- Anderson, Oscar Daniel, Ph D Cornell Univ , Dept of Psychology, Ithaca, N Y (1, 1939)
- Anderson, Rubert S , Ph D Univ of South Dakota School of Medicine, Vermillion *Prof of Physiology* (1, 1948)
- Anderson, Rudolph J , Ph D Sterling Lab , Yale Univ , New Haven, Conn *Prof of Chemistry* (2, 1915)
- Anderson, W A D , M A , M D Marquette Univ School of Medicine, Milwaukee, Wis *Prof of Pathology and Bacteriology* (4, 1941)
- Anderson, William E , M A Eastern State Farmers' Exchange, Westbrook Farm, Rockville, Conn *Biochemist* (2, 1931, 5, 1933)
- Andervont, H B , Sc D Natl Cancer Inst , Bethesda, Md *Biologist, USPHS* (4, 1939)
- Andrews, James C , Ph D Univ of North Carolina, Chapel Hill *Prof of Biological Chemistry and Nutrition* (2, 1925)
- Andrus, E Cowles, M D 24 E Eager St , Baltimore 2, Md *Asst Visiting Physician, Assoc Prof of Medicine, Johns Hopkins Univ* (1, 1925)
- Anfinsen, Christian B , Jr , Ph D Harvard Univ Med School, 25 Shattuck St , Boston 15, Mass *Asst Prof , Div of Biophysics* (2, 1946)
- Angerer, Clifford, Ph D Ohio State Univ , Columbus *Assoc Prof of Physiology* (1, 1943)
- Angevine, D Murray, M D Univ of Wisconsin Med School, Madison *Prof of Pathology* (4, 1940)
- Anker, H S , M D , Ph D Univ of Chicago, Dept of Biochemistry, 947 E 58th St , Chicago 37, Ill *Research Assoc and Asst Prof* (2, 1949)
- Annegers, John H , Ph D , M D Northwestern Univ Med School, Dept of Physiology, 313 E Chicago Ave , Chicago 11, Ill *Asst Prof of Physiology* (1, 1949)
- Ansbacher, Stefan, D Sc 17 Loel Court, Rockville Center, N Y (2, 1939)
- Anslow, W Parker, Jr , Ph D New York Univ College of Medicine, 477 First Ave , New York City 16 *Asst Prof of Physiology* (2, 1948)
- Anson, Mortimer L , Ph D Continental Foods, Inc , Hoboken, N J *Dir of Chemical Research* (2, 1937)
- Apperly, Frank L , M A , D Sc , M D Med College of Virginia, Richmond *Prof of Pathology* (4, 1936)
- Archibald, Reginald M , Ph D , M D Rockefeller Inst for Med Research, 66th St and York Ave , New York City 21 *Member, Physician to Hospital* (2, 1947)
- Arkin, Aaron, M D , Ph D Suite 2006, 25 E Washington St , Chicago, Ill *Rush Prof of Medicine, Univ of Illinois, Prof and Chairman of Dept of Medicine, Cook County Grad School* (1, 1914, 3, 1919)
- Armstrong, Harry G , M D Headquarters US Air Force Washington, 25, DC *Surgeon General* (1, 1948)

- Armstrong, Philip B**, M D Syracuse Univ College of Medicine, Syracuse 10, N Y *Prof of Anatomy* (1, 1945)
- Armstrong, W D**, M D, Ph D Univ of Minnesota, 17 Med Sciences Bldg, Minneapolis *Prof and Head of Physiological Chemistry* (2, 1938)
- Arnold, Aaron**, Ph D Sterling-Winthrop Research Inst, Rensselaer, N Y *Head of Nutritional Research Lab* (5, 1947)
- Arnold, Lloyd, A M**, M D 1538 E 57th St, Chicago, Ill (4, 1930, 6, 1925)
- Arnow, L Earle**, Ph D, M D Sharp & Dohme, Med Research Div, Glenolden, Pa *Dir of Research* (2, 1940)
- Aronson, Joseph D**, M D Univ of Pennsylvania, Phipps Inst, Philadelphia 4 *Assoc Prof of Bacteriology* (4, 1927, 6, 1925)
- Artom, Camillo**, M D Wake Forest College, Bowman Gray School of Medicine, Winston-Salem, N C *Prof of Biochemistry* (2, 1944)
- Ascham, Leah**, Ph D Kansas State College, Manhattan *Prof in School of Home Economics* (5, 1935)
- Asenjo, Conrado F**, Ph D School of Tropical Medicine, San Juan, Puerto Rico *Assoc Prof of Chemistry and Head of Dept of Chemistry and Nutrition* (2, 1944)
- Ashburn, Llewellyn L**, M D U S Marine Hospital, Baltimore 11, Md *Sr Surgeon, U S Public Health Service* (4, 1947)
- Ashby, Winifred M**, Ph D 305 10th St, N E Washington, D C *Sr Scientist, Federal Security Agency* (6, 1923)
- Ashman, Richard**, Ph D Louisiana State Univ School of Medicine, New Orleans *Prof of Physiology* (1, 1925)
- Astwood, Edwin Bennet**, M D, Ph D Pratt Diagnostic Hospital, 30 Bennet St, Boston, Mass *Research Prof of Medicine, Tufts Med School* (1, 1939)
- Atkin, Lawrence**, Ph D The Fleischmann Labs, 810 Grand Concourse, New York City 51 *Asst to Dir of Research* (2, 1946, 5, 1946)
- Aub, Joseph C**, M D Massachusetts General Hospital, Fruit St, Boston 14 *Prof of Research Medicine, Harvard Med School* (1, 1919, 5, 1933)
- Austin, J Harold**, M D 711 Maloney Clinic, 36th and Spruce Sts, Philadelphia 4, Pa *Dir of Pepper Lab* (2, 1922)
- Avery, O T**, M D, Sc D Hoods Hill Rd, Nashville, Tenn *Member Emeritus, Rockefeller Inst for Med Research* (4, 1921, 6R, 1920)
- Axelrod, A E**, Ph D Univ of Pittsburgh, Dept of Chemistry, Pittsburgh, Pa *Research Biochemist, Inst of Pathology, Western Pennsylvania Hospital, Asst Research Prof, Dept of Chemistry* (5, 1949)
- Axelrod, Bernard**, Ph D Western Regional Research Lab, 800 Buchanan St, Albany, Calif *Assoc Chemist, Enzyme Research Div* (2, 1948)
- Axtmayer, Joseph H**, Ph D Univ of Puerto Rico, Rio Piedras *Prof of Chemistry* (5, 1935)
- Bach, L M N**, Ph D Tulane Univ School of Medicine, New Orleans, La *Prof of Physiology* (1, 1948)
- Bachem, Albert**, Ph D Univ of Illinois College of Medicine, Chicago 12 *Prof of Biophysics* (1, 1933)
- Bachman, Carl**, M D Univ of Pennsylvania School of Medicine, 3400 Spruce St Philadelphia 4 *Prof and Dir of Obstetrics and Gynecology* (2, 1941)
- Bachrach, William H**, M D, Ph D Univ of Southern California School of Medicine, Dept of Physiology, Los Angeles 7 *Research Assoc* (1, 1949)
- Baer, Erich**, Ph D Banting Inst, Banting and Best Dept of Med Research, 100 College St, Toronto, Ont, Canada *Assoc Prof* (2, 1942)
- Baernstein, Harry D**, Ph D Natl Insts of Health, Bethesda, Md *Sr Biochemist* (2, 1934)
- Baetjer, Anna M**, D Sc Johns Hopkins School of Hygiene and Public Health, 615 N Wolfe St, Baltimore 5, Md *Asst Prof of Physiological Hygiene* (1, 1929)
- Bahrs, Alice M**, Ph D 2735 Orchard St, Corvallis Ore (1, 1933)
- Bailey, Cameron Vernon**, C M, M D New York Univ and Hospital 303 E 20th St, New York City *Chn Prof of Medicine* (2, 1920, 5, 1933)
- Bailey, Orville T**, M D Harvard Univ Med School, 25 Shattuck St, Boston 15, Mass *Asst Prof of Pathology* (4, 1939)
- Bailey, Percival**, M D, Ph D Univ of Illinois College of Medicine, 1853 W Polk St, Chicago 12, Ill *Prof of Neurology and Neurosurgery* (1, 1941)
- Baitsell, George Alfred**, Ph D Yale Univ, Osborn Zoological Lab, 165 Prospect St, New Haven, Conn *Prof of Biology* (1, 1915)
- Baker, A B**, M D Univ of Minnesota Hospital, 19 Millard Hall, Minneapolis *Dir and Prof of Neurology and Neuropathology* (4, 1940)
- Baker, James A**, D V M, Ph D Cornell Univ New York State Veterinary College, Ithaca *Prof of Bacteriology* (4, 1947)
- Baker, Roger D**, M D Med College of Alabama, Birmingham 5 *Prof of Pathology* (4, 1939)
- Baldes, Edward J**, Ph D 427 Fifth Ave, S W, Rochester, Minn *Asst Prof of Physics, Mayo Foundation, Univ of Minnesota Grad School* (1, 1930)
- Baldwin, Francis Marsh**, Ph D Univ of Southern California, Los Angeles *Prof of Zoology and Dir of Exper Marine Biology* (1, 1919)
- Bale, William F**, Ph D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Prof of Radiation Biology* (1, 1943)

- Ball, Eric G**, Ph D Harvard Med School, 25 Shattuck St, Boston 15, Mass *Prof of Biological Chemistry* (2, 1934)
- Ball, Howard A**, M D 233 A St, San Diego, Calif *Pathologist, Paradise Valley Hospital* (4, 1937)
- Balls, Arnold Kent**, Ph D Enzyme Research Lab, U S Bureau of Agricultural and Industrial Chemistry, Western Regional Research Lab, 800 Buchanan St, Albany 6, Calif *Head Chemist* (2, 1932)
- Bang, Frederick B**, M D Johns Hopkins Hospital, Baltimore, Md *Assoc Prof in Medicine* (4, 1947)
- Banus, Mario Garcia**, D Sc Bright Meadows, Chestertown, Md (1, 1927)
- Bard, Philip**, Ph D, Johns Hopkins Univ School of Medicine, 710 N Washington St, Baltimore, Md *Prof and Dir of Dept of Physiology* (1, 1929)
- Barker, H A**, Ph D Univ of California, 3048 Life Sciences Bldg, Berkeley 4, *Prof of Plant Nutrition (Agric)* (2, 1946)
- Barker, S B**, Ph D State Univ of Iowa College of Medicine, Iowa City *Assoc Prof of Physiology* (1, 1938)
- Barlow, O W**, M D, Ph D 3 Warwick Rd, Winchester, N H (3, 1944)
- Barnes, B O**, Ph D Box 967, Station Hospital, KAAF, Kingman, Ariz *Prof of Health Education, Univ of Denver* (1, 1932)
- Barnes, LaVerne A**, Ph D Naval Med Research Inst, Natl Naval Med Center, Bethesda 14, Md *Head, Bacteriology Facility* (6, 1931)
- Barnes, Richard Henry**, Ph D Sharp & Dohme, Glenolden, Pa *Dir of Biochemical Research, Med Research Div* (2, 1941, 5, 1944)
- Barnes, Thomas C**, D Sc Hahnemann Med College and Hosp of Philadelphia, Philadelphia, Pa *Assoc Prof of Pharmacology* (1, 1942, 3, 1948)
- Barnum, Cyrus P, Jr**, Ph D Univ of Minnesota, 210 Millard Hall, Minneapolis 14 *Assoc Prof of Physiological Chemistry* (2, 1946)
- Barott, Herbert G**, E E U S Dept of Agriculture, Natl Agricultural Research Center, Beltsville, Md *Biophysicist, Animal Nutrition Div, Bur of Animal Industry* (5, 1938)
- Barrera, S Eugene**, M D Albany Med College, New Scotland Ave, Albany, N Y (1, 1937)
- Barron, Donald H**, Ph D Yale Univ School of Medicine, New Haven, Conn *Assoc Prof of Physiology* (1, 1943)
- Barron, L S Guzman**, M D Univ of Chicago, Dept of Medicine, Chicago 37, Ill *Assoc Prof of Biochemistry* (2, 1931)
- Bartley, S Howard**, Ph D P O Box 763, East Lansing, Mich (1, 1935)
- Bass, Allan D**, M D Univ of Syracuse School of Medicine, Syracuse, N Y *Prof of Pharmacology* (3, 1944)
- Batchelder, Esther L**, Ph D 8433 Woodcliff Court, Silver Spring, Md *Head of Food and Nutrition Div, Bureau of Human Nutrition and Home Economics* (5, 1933)
- Bateman, John B**, Ph D Physical and Chemical Div, Camp Detrick, Frederick, Md (1, 1945)
- Bates, Robert W**, Ph D E R Squibb and Sons, Biological Labs, New Brunswick, N J *Head of Endocrine Development Dept* (2, 1936)
- Batson, Herbert C**, Ph D Army Med Center, AMDR & GS, Washington, D C *Scientific Dir, Dept of Biological Products* (6, 1949)
- Batterman, Robert C**, M D New York Univ College of Medicine, 477 First Ave, New York City *Instr in Therapeutics* (3, 1941)
- Baudisch, Oskar**, Ph D Saratoga Springs, N Y *Dir of Research, Saratoga Springs Authority of the State of New York* (2, 1931)
- Bauer, J H**, M D Rockefeller Foundation, 20 Rue de la Baume, Paris, (8^e) France (4, 1935)
- Bauer, Walter**, M D Massachusetts General Hospital, Boston *Assoc Prof and Tutor in Medicine, Harvard Med School* (1, 1929)
- Bauernfeind, J C**, Ph D Hoffmann-LaRoche, Inc, Nutley 10, N J *Chief of Applied Nutrition* (5, 1947)
- Bauman, Louis**, M D Columbia Presbyterian Med Center, 180 Fort Washington Ave New York City 32 *Asst Prof of Clin Medicine (retired), Columbia Univ* (2, 1912)
- Baumann, Carl A**, Ph D Univ of Wisconsin, Biochemistry Dept, Madison *Prof of Biochemistry* (2, 1938, 5, 1938)
- Baumann, Emil J**, Ph D 7 Church Lane, Scarsdale, N Y *Chemist, Montefiore Hospital* (2, 1922)
- Baumberger, J Percy**, Sc D Stanford Univ, Physiology Dept, Stanford Univ, Calif *Prof of Physiology* (1, 1921)
- Baxter, James H**, M D Johns Hopkins Hospital, Dept of Medicine, Baltimore, Md (3, 1948)
- Bayne-Jones, Stanhope**, M A, M D New York Hospital, Cornell Med Center, 525 E 68th St, New York City 21 *Pres, Joint Admin Board* (4, 1927, 6, 1917)
- Bazett, Henry C**, M A, M D Univ of Pennsylvania School of Medicine, Philadelphia *Prof of Physiology* (1, 1921)
- Beach, Elot F**, Ph D Metropolitan Life Insurance Co, 1 Madison Ave, New York City 10 *Research Biochemist* (2, 1941, 5, 1942)
- Beadle, Buell W**, M S, Ph D George W Gooch Lab, Ltd, 2580 E 8th St, Los Angeles 23, Calif *Director* (2, 1947)
- Bean, John W**, Ph D, M D Univ of Michigan, Ann Arbor *Prof of Physiology* (1, 1932)
- Beard, Howard H**, Ph D Terrell's Labs of

- Clinical Medicine, Med Arts Bldg, Rm 24, Fort Worth, Tex *Biochemist* (2, 1928, 5, 1933)
- Beard, Joseph W**, M D Duke Hospital, Durham, N C *Prof of Surgery, Assoc Prof of Virology* (4, 1938, 6, 1940)
- Beatty, Clarissa H**, Ph D Univ of Oregon Med School, Portland *Research Fellow* (1, 1949)
- Beazell, James Myler**, Ph D, M D 104 S Michigan Ave, Chicago, Ill *Instr in Physiology and Pharmacology, Northwestern Univ School of Medicine* (1, 1939)
- Beck, Claude S**, M D Lakeside Hospital, Cleveland, Ohio *Prof of Neurosurgery, Western Reserve Univ, Assoc Surgeon, Lakeside Hospital* (4, 1930)
- Beck, Lyle V**, Ph D 5609 Roosevelt St, Bethesda, Md (1, 1941)
- Becker, R Frederick**, M S, Ph D Daniel Baugh Inst of Anatomy, 307 S 11th St, Philadelphia, Pa (1, 1949)
- Beckman, Harry**, M D Marquette Univ School of Medicine, Milwaukee, Wis *Prof and Dir of Dept of Pharmacology* (3, 1937)
- Beecher, Henry K**, M D Massachusetts General Hospital, Boston *Anesthetist-in-Chief, Dorr Prof of Research in Anesthesia, Harvard Med School* (3, 1940)
- Behnke, Albert R**, M S, M D Naval Med Research Inst, Bethesda, Md *Exec Dir* (1, 1946)
- Behre, Jeanette Allen**, Ph D Columbia Univ College of Physicians and Surgeons, Dept of Biochemistry, 630 W 168th St, New York City 32 *Associate* (2, 1925)
- Behrens, Otto K**, Ph D Lilly Research Labs, Eli Lilly and Co, Indianapolis 6, Ind *Head, Bio-organic Chemical Research* (2, 1949)
- Behrmann, Vivian G**, Ph D Wayne Univ, Detroit, Mich *Instr, Grad School, Res Physiologist, Henry Ford Hospital* (1, 1948)
- Belding, David L**, M D Boston Univ School of Medicine, Boston, Mass *Prof Emeritus of Bacteriology and Exper Pathology* (4, 1927)
- Belding, Harwood S**, Ph D QMC Climatic Lab, Lawrence, Mass *Director* (1, 1945)
- Belkin, Morris**, Ph D Natl Cancer Inst, Bethesda 14, Md *Sr Pharmacologist* (3, 1949)
- Bell, E T**, M D 110 Anatomy Bldg, Univ of Minnesota, Minneapolis *Prof Emeritus of Pathology* (4, 1931)
- Bender, M B**, M D New York Univ College of Medicine, New York City *Assoc Prof of Neurology and Head of Lab of Exper Medicine* (1, 1947)
- Benditt, Earl P**, M D Univ of Chicago Clinics, Dept of Pathology, Chicago 37, Ill *Asst Prof* (4, 1947)
- Benham, Olive Ray**, B S Connecticut State Dept of Health, Bureau of Labs, Hartford *Chief Serologist* (6, 1944)
- Bennett, A Lawrence**, Ph D, M D Univ of Nebraska College of Medicine, Omaha *Prof of Physiology and Pharmacology* (1, 1941)
- Bennett, Granville A**, M D Univ of Illinois College of Medicine, 1853 W Polk St, Chicago *Prof of Pathology* (4, 1931)
- Bennett, Henry S**, M D Univ of Washington School of Medicine, Seattle *Dept of Anatomy* (1, 1946)
- Bennett, Leslie L**, M D Univ of California, Berkeley 4 *Asst Prof of Physiology* (1, 1945)
- Bennett, Mary Adelia**, Ph D Inst for Cancer Research, 7701 Burholme St Fox Chase, Philadelphia 11, Pa *Research Biochemist* (2, 1941)
- Benson, Clara C**, Ph D 160 Dorset St, West, Port Hope, Ontario, Canada *Prof Emeritus of Food Chemistry, Univ of Toronto* (2, 1906)
- Benton, Joseph G**, Ph D, M D Goldwater Memorial Hospital, 111 New York Univ Med Research Service, Welfare Island 17, N Y *Research Asst, Instr in Physical Medicine, New York Univ College of Medicine* (3, 1949)
- Berg, Benjamin N**, M D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Assoc in Pathology* (4, 1928)
- Berg, Clarence P**, Ph D State Univ of Iowa, Dept of Biochemistry, Chemistry Bldg, Iowa City *Prof of Biochemistry* (2, 1933, 5, 1936)
- Berg, William N**, Ph D 225 W 106th St, New York City *Biochemist* (2, 1906)
- Bergeim, Olaf**, Ph D Univ of Illinois College of Medicine, 1853 W Polk St, Chicago 12 *Prof of Biochemistry* (1, 1916, 2, 1914)
- Bergmann, Werner**, Ph D Yale Univ, Sterling Chemistry Lab, New Haven, Conn *Prof of Chemistry* (2, 1934)
- Berkson, Joseph**, M D, D Sc Mayo Clinic, Rochester, Minn (1, 1933)
- Bernard, Richard**, Ph D Laval Univ, Dept of Biology, Blvd de l'Entente, Quebec, Canada *Asst Prof of Physiology* (1, 1947)
- Bernheim, Frederick**, Ph D Box 3109, Duke Univ Med School, Durham, N C *Prof of Pharmacology* (2, 1933, 3, 1935)
- Bernthal, Theodore G**, M S, M D Med College, State of South Carolina, Dept of Physiology, Charleston 16 *Prof of Physiology* (1, 1932)
- Berry, George Packer**, M D Harvard Med School, Boston 15, Mass *Dean and Prof of bacteriology* (4, 1938, 6, 1934)
- Berryman, George H**, Ph D 6012 Woodlawn Ave, Chicago 37, Ill *Head of Nutrition Div, QM Food and Container Inst* (1, 1949)
- Bessey, Otto A**, Ph D Univ of Illinois College of Medicine, 1853 W Polk St, Chicago 12 *Prof and Head of Dept of Biological Chemistry* (2, 1938, 5, 1943)
- Best, Charles H**, M D, D Sc Univ of Toronto Toronto, Ontario, Canada *Dir of Banting and*

- Best Dept of Med Research and Dept of Physiology* (1, 1923, 2, 1923)
- Bethell, Frank H**, M D 409 Lenawee Drive, Ann Arbor, Mich *Prof of Internal Medicine and 1st Dir of the Thomas Henry Simpson Memorial Inst* (4, 1936)
- Bethke, Roland M**, Ph D Ohio Agricultural Exper Station, Wooster *In Charge of Nutritional Investigations* (2, 1928, 5, 1933)
- Beutner, R**, M D, Ph D 235 N 15th St, Philadelphia, Pa *Prof and Head of Dept of Pharmacology, Hahnemann Med College* (1, 1921, 3, 1921)
- Beyer, Karl H**, Ph D, M D Sharp & Dohme, Inc Med Research Div, Glenolden, Pa *Dir of Pharmacological Research* (1, 1942, 3, 1944)
- Bickford, Reginald G**, M D Mayo Clinic, Section on Physiology, Rochester, Minn *Head of Lab of Neurophysiology and Electroencephalography* (1, 1949)
- Bier, Otto**, M D Instituto Biologico, Caixa Postal 119A, São Paulo, Brazil, (6, 1947)
- Breter, Raymond N**, M D, Ph D Univ of Minnesota, Minneapolis *Prof of Pharmacology* (3, 1930)
- Bills, Charles E**, Ph D Stringtown Rd Route 12, Evansville, Ind *Independent Investigator* (2, 1928, 5, 1935)
- Bing, Franklin C**, Ph D 1135 Fullerton Ave, Chicago, Ill *Dir of American Inst of Baking, Asst Prof of Physiology, Northwestern Univ Med School* (2, 1931, 5, 1934)
- Bing, Richard J**, M D Johns Hopkins Hospital, Dept of Surgery, Baltimore 5, Md *Assoc Prof of Medicine and Surgery* (1, 1942)
- Binkley, Francis**, Ph D Univ of Utah School of Medicine, Salt Lake City *Assoc Prof* (2, 1947)
- Binkley, Stephen Bennett**, Ph D Bristol Labs, Inc, Syracuse 1, N Y *Asst Dir of Research* (2, 1911)
- Bird, Herbert R**, Ph D Bureau of Animal Industry, Agricultural Research Center, Beltsville, Md *Sr Biochemist* (5, 1947)
- Bird, Orson D**, Ph D Parke, Davis and Co, Research Labs, Detroit 32, Mich *Research Biochemist* (2, 1947)
- Bisbey, Bertha**, Ph D Univ of Missouri, Gwynn Hall, Columbia *Prof of Nutrition* (5, 1933)
- Bischoff, Fritz E**, Ph D Cottage Hospital, Santa Barbara, Calif *Dir of Research* (2, 1928, 5, 1933)
- Bishop, George H**, Ph D Washington Univ Med School Euclid and Kingshighway, St Louis, Mo *Prof of Biophysics* (1, 1923)
- Biskind, Gerson R**, M D 210 Stockton St, San Francisco, Calif *Pathologist, Mt Zion Hospital, Clin Instr in Pathology, Univ of California Med School* (4, 1914)
- Black, Alex**, Ph D Pennsylvania State College, Dept of Animal Nutrition, State College *Prof of Animal Nutrition* (5, 1947)
- Black, Edgar C**, Ph D Univ of British Columbia, Dept of Biology and Botany, Vancouver, B C, Canada (1, 1943)
- Black, Simon**, Ph D Univ of Chicago, Chicago 37, Ill *Asst Prof of Biochemistry, Dept of Medicine* (2, 1948)
- Blair, Edgar A**, Ph D Field Research Lab, Med Dept, Fort Knox, Ky *Lt Col* (1, 1936)
- Blair, Henry A**, Ph D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Prof of Physiology and Dir of Dept of Radiation Biology* (1, 1934)
- Blake, Francis G**, M D, Sc D Yale Univ School of Medicine, New Haven, Conn *Sterling Prof of Medicine* (4, prior to 1920, 6, 1921)
- Blanchard, Ernest W**, Ph D Schieffelin and Co, 30 Cooper Sq, New York City 3 *Dir of Research* (1, 1946)
- Blankenhorn, M A**, M D Univ of Cincinnati, Cincinnati, Ohio *Prof of Medicine* (4, 1932)
- Blatherwick, Norman R**, Ph D Metropolitan Life Insurance Co, 1 Madison Ave, New York City *Dir of Biochemical Lab* (1, 1915, 2, 1915, 5, 1934)
- Blau, Nathan F**, Ph D Veterans Admin Hospital, 401 S Holyoke Ave, Wichita 8, Kan *Research Biochemist* (2, 1928)
- Blish, Morris J**, Ph D Internatl Minerals and Chemical Corp, Box G, Rossford, Ohio *Research Dir* (2, 1944)
- Bliss, Alfred**, Ph D Tufts College Med School, Boston, Mass *Assoc Prof of Physiology* (1, 1947)
- Bliss, Chester Itiner**, Ph D Conn Agricultural Exper Station, P O Box 1106, New Haven *Biometrician, Lecturer in Biometry, Yale Univ* (3, 1944)
- Bliss, Eleanor A**, Sc D Johns Hopkins Hospital, Dept of Preventive Medicine, 615 N Wolfe St, Baltimore, Md *Assoc in Preventive Medicine, Johns Hopkins Univ School of Medicine* (6, 1931)
- Bloch, Konrad**, Ph D Univ of Chicago, Dept of Biochemistry, Chicago 37, Ill *Assoc Prof of Biochemistry* (2, 1944)
- Block, Richard J**, Ph D 15 Cooper Rd, Searsdale, N Y *Dir of Research, C M Armstrong Co, Assoc Dept of Physiology and Biochemistry, New York Med College, Flower and Fifth Ave Hospital* (2, 1934, 5, 1933)
- Block, Walter D**, Ph D 813 E McCreight Ave, Springfield, Ohio, (2, 1942)
- Bloom, William**, M D 1410 E 56th St, Chicago, Ill *Prof of Anatomy, Univ of Chicago* (4, 1930)
- Bloomfield, A L**, M D Stanford Univ Hospital, San Francisco, Calif *Prof of Medicine* (3, 1927, 4, 1927)

- Bloor, W R , Ph D Univ of Rochester School of Medicine and Dentistry, Rochester 7, N Y *Prof of Biochemistry* (1R, 1915, 2, 1910)
- Blum, Harold F , Ph D Princeton Univ , Dept of Biology, Princeton, N J *Physiologist, Natl Cancer Inst , and Visiting Lecturer* (1, 1928)
- Blumberg, Harold, Sc D Research Lab , Endo Products, Inc , 84-40 101st St , Richmond Hill 18, N Y (5, 1942)
- Blumenstock, Julius, M D Veterans Admin Hospital, Sheridan, Wyo (1, 1925)
- Blumgart, Herrmann L , M D Beth Israel Hospital, 330 Brookline Ave , Boston, Mass *Physician-in-Chief, Prof of Medicine, Harvard Med School* (1, 1927)
- Blunt, Katharine, Ph D 38 Glenwood Ave , New London, Conn *Pres Emeritus, Connecticut College for Women* (2, 1921)
- Bobb, J Richard R , M D Univ of Minnesota Med School, Dept of Physiology, Minneapolis 14 *Instr in Physiology, U S Public Health Postdoctorate Research Fellow* (1, 1949)
- Bock, Joseph C , Ph D 2324 N 46th St , Milwaukee 10, Wis *Prof Emeritus of Biochemistry, Marquette Univ Med School, Biochemist, Milwaukee County Hospital* (2, 1916)
- Bodansky, Aaron, Ph D Hospital for Joint Diseases, 1919 Madison Ave , New York City *Biological Chemist* (2, 1926)
- Bodansky, Oscar, Ph D , M D Memorial Hospital Cancer Center, 444 E 68th St , New York City 21 *Chief, Clin Biochemistry, Assoc Member, Sloan-Kettering Inst for Cancer Research* (2, 1937, 3, 1942)
- Bodian, David, Ph D , M D Johns Hopkins Univ , 1901 E Madison St , Baltimore, Md *Assoc Prof of Epidemiology* (6, 1949)
- Bodine, Joseph Hall, Ph D State Univ of Iowa, Iowa City *Prof and Head of Dept of Zoology* (1, 1925)
- Boell, Edgar J , Ph D Yale Univ , Osborn Zoological Lab , New Haven, Conn *Ross G Harrison Prof of Exper Zoology* (1, 1942)
- Boger, William P , M D Sharp & Dohme, Inc , Med Research Div , Glenolden, Pa *Assoc Med Dir , Instr in Medicine, Univ of Pennsylvania School of Medicine and Grad School of Medicine* (3, 1948)
- Bogert, L Jean, Ph D Hotel Claremont, Berkeley, Calif (2, 1917)
- Bogert, Marston Taylor, Sc D 1158 Fifth Ave , New York City 29 *Prof Emeritus of Organic Chemistry, Columbia Univ , Scientific Consultant to Evans Research and Development Corp* (2, 1925)
- Bohr, David F , M D Univ of Michigan, Physiology Lab , Ann Arbor *Asst Prof* (1, 1949)
- Boivin, André, M D La Faculté de Médecine de Strasbourg, Strasbourg, France *Professor* (6, 1949)
- Bolliger, Adolph, Ph D Univ of Sydney, Gordon Craig Research Lab , Sydney, Australia *Dir of Research* (2, 1928)
- Bollman, J L , M D Mayo Clinic, Rochester, Minn *Chairman of Div of Exper Medicine, Prof of Physiology, Mayo Foundation* (4, 1927)
- Bond, Glenn C , Ph D , M D The Upjohn Co , Research Lab , Kalamazoo, Mich *Asst Dept Head of Bacteriology Research* (6, 1939)
- Bondi, Amedeo Hahnemann Med College, Philadelphia, Pa *Prof and Head of Dept of Bacteriology* (6, 1948)
- Bonner, David M , Ph D Yale Univ , Osborn Botanical Lab , New Haven, Conn *Assoc Prof and Research Assoc* (2, 1948)
- Bonnycastle, Desmond D , M D , Ph D Yale Univ School of Medicine, New Haven, Conn *Asst Prof of Pharmacology* (3, 1947)
- Bonsnes, Roy W , Ph D Cornell Univ Med College, 1300 York Ave , New York City 21 *Asst Prof of Biochemistry in Obstetrics* (2, 1947)
- Booher, Lela E , Ph D General Mills, Inc , 1081 21st Ave , S E , Minneapolis, Minn *Chief Nutritionist and Dir of Nutrition Lab* (2, 1933, 5, 1933)
- Booker, Walter M , Ph D Howard Univ School of Medicine, Washington, D C *Assoc Prof of Pharmacology* (1, 1948, 3, 1948)
- Boor, Alden K , Ph D Camp Detrick, Basic Science Div , Frederick, Md (2, 1931)
- Boothby, Walter M , M A , M D Univ of Lund, Lund, Sweden *Research Consultant Aviation Medicine Inst of Physiology, Chief Emeritus, Clin Metabolism Sect , Mayo Clinic* (1R, 1915, 2, 1920, 3R, 1923, 4R, 1924)
- Bordley, James, III, M D Mary Imogene Bassett Hospital, Cooperstown, N Y (1, 1938)
- Borek, Ernest, Ph D College of the City of New York, Convent Ave and 140th St , New York City *Asst Prof , Research Assoc in Biochemistry, Columbia Univ* (2, 1947)
- Boroff, Daniel A , M A , M S 1721 Ashland Ave , Evanston, Ill (6, 1947)
- Borsook, Henry, M D , Ph D California Inst of Technology, Pasadena 4 *Prof of Biochemistry* (2, 1931)
- Bosshardt, David K , Ph D Sharp & Dohme, Med Research Div , Glenolden, Pa *Research Biochemist* (5, 1947)
- Bostick, Warren L , M D Univ of California Med School, Dept of Pathology, San Francisco 22, *Asst Prof of Pathology* (4, 1949)
- Bosworth, Alfred Willson, A M , M D R F D 4, Circleville, Ohio *Consulting Chemist* (2, 1936, 5, 1935)
- Bott, Phyllis A , Ph D Woman's Med College of Pennsylvania, Henry Ave and Abbotsford Rd ,

- Philadelphia *Prof and Chairman of Dept of Physiological Chemistry* (2, 1938)
- Boucher, Robert V**, Ph D 303 Frear Labs, State College, Pa *Prof of Agricultural and Biological Chemistry* (5, 1945)
- Bouman, H D**, M D Univ of Wisconsin Med School, Madison *Prof of Physical Medicine* (1, 1943)
- Bourne, Wesley, M D**, M Sc McGill Univ, Montreal, Quebec, Canada *Prof of Anesthesia* (3, 1936)
- Bourque, Joseph E**, M D, Ph D Univ of Illinois College of Medicine, Dept of Physiology, 1853 W Polk St, Chicago 12 *Asst Prof of Physiology* (1, 1949)
- Bourquin, Helen**, Ph D 1331 N Tejon St, Colorado Springs, Colo (1, 1925)
- Bowen, William J**, Ph D USPHS, Inst of Exper Biology & Medicine, Bethesda 14, Md *Sr Asst Scientist* (1, 1948)
- Bowman, Donald E**, Ph D 6956 Warwick Rd, Indianapolis, Ind *Assoc Prof of Biochemistry, Indiana Univ School of Medicine* (2, 1944)
- Bowman, Katherine L**, B A 20 Plaza St, Brooklyn 17, N Y (6, 1946)
- Boxer, George E**, Ph D 605 Girard Ave, Westfield, N J *Sr Chemist, Research and Development Div, Merck & Co, Inc* (2, 1946)
- Boyd, Eldon M**, M A, M D Queen's Univ, Kingston, Ontario, Canada *Prof and Head of Dept of Pharmacology* (3, 1941)
- Boyd, M John**, Ph D Hahnemann Med College, 235 N 15th St, Philadelphia 2, Pa *Prof of Biol Chemistry* (2, 1947)
- Boyd, T E**, Ph D 9 Walworth Ave, Scarsdale, N Y (1, 1924)
- Boyd, William C**, Ph D Boston Univ School of Medicine, 80 E Concord St, Boston, Mass *Assoc Prof of Biochemistry* (6, 1933)
- Boyden, Allan A** Rutgers Univ, New Brunswick, N J *Prof of Zoology* (6, 1948)
- Boyden, Edward A**, Ph D Univ of Minnesota, Minneapolis 14 *Prof and Chairman of Dept of Anatomy* (1, 1929)
- Boyer, Paul D**, Ph D Univ of Minnesota College of Agriculture, Div of Biochemistry, St Paul 1 *Assoc Prof* (2, 1944)
- Boyle, Paul E**, D M D Univ of Pennsylvania School of Dentistry, 40th and Spruce Sts, Philadelphia 4 *Prof of Oral Pathology* (4, 1939)
- Bozicevich, John**, M A USPHS, Natl Insts of Health, Bethesda, Md *Head, Subsection of Immunology, Trop Diseases Div* (6, 1948)
- Bozler, Emil**, Ph D Ohio State Univ, Columbus *Prof of Physiology* (1, 1932)
- Bradbury, James T**, Sc D Univ of Louisville School of Medicine, 101 W Chestnut St, Louisville 2, Ky (1, 1941)
- Bradley, Harold C**, Ph D 2639 Durant Ave, Berkeley, Calif (1, 1911, 2, 1908)
- Bradley, Stanley E**, M D Columbia Univ College of Physicians and Surgeons, 620 W 168th St, New York City 32 *Asst Prof* (1, 1947)
- Bradley, William B**, Ph D American Inst of Baking, 1046 Elmwood Ave, Wilmette, Ill *Dir of Labs* (1, 1939)
- Branch, Charles F**, M D American College of Surgeons, 40 E Erie St, Chicago 11, Ill *Asst Dir* (4, 1940)
- Branch, E Arnold G**, M D Lancaster Hospital, St John, New Brunswick, Canada *Dir of Labs* (4, 1929)
- Brand, Erwin**, Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Assoc Prof of Biological Chemistry* (2, 1929)
- Brandes, W W**, M D Roosevelt Hospital, W 59th St, New York City (4, 1931)
- Branham, Sara E**, Ph D, M D, Natl Insts of Health, Bethesda, Md *Sr Bacteriologist* (6, 1926)
- Branion, Hugh Douglas**, Ph D Ontario Agricultural College, Guelph, Canada *Prof and Head of Dept of Animal Nutrition* (5, 1933)
- Brassfield, Charles R**, Ph D Univ of Michigan, Ann Arbor *Assoc Prof of Physiology* (1, 1937)
- Bratton, Andrew Calvin, Jr**, M D, Ph D Parke, Davis and Co, Research Labs, Detroit 32, Mich *Dir of Pharmacological Research* (3, 1941)
- Brauer, Ralph W**, Ph D Louisiana State Univ School of Medicine, New Orleans *Asst Prof of Pharmacology* (3, 1948)
- Braun, Herbert A**, Ph D Fed Security Agency, Food and Drug Admin, Washington, D C *Assoc Pharmacologist* (3, 1941)
- Brazier, Mary A B**, Ph D Massachusetts General Hospital, Electroencephalographic Lab, Boston 14 *Research Assoc in Neuropathology, Harvard Med School* (1, 1947)
- Brecher, George**, M D Natl Insts of Health, Bethesda 14, Md *Chief of Unit on Morphologic Hematology* (4, 1949)
- Brecher, Gerhard A**, M D, Ph D Western Reserve Univ Med School, Dept of Physiology, Cleveland 6, Ohio *Sr Instructor* (1, 1949)
- Breedis, Charles**, M D Univ of Pennsylvania School of Medicine, Philadelphia *Instr in Pathology* (4, 1948)
- Brewer, Carl R**, Ph D Camp Detrick, Frederick, Md *Chief, Bacterial Nutrition Branch, Biological Div, Chemical Corps* (2, 1948)
- Brewer, John H**, Ph D Hynson Westcott and Dunning, Baltimore, Md *Dir of Biological Research* (6, 1948)
- Brewer, Nathan R**, Ph D Univ of Chicago, Chicago, Ill *Lecturer in Physiology* (1, 1948)
- Bridge, Edward M**, M D Univ of Buffalo School of Medicine, 24 High St, Buffalo 9, N Y *Prof of Pharmacology* (2, 1940)

- Briggs, A P , M D Univ of Georgia Med College, Augusta *Prof of Biochemistry* (2, 1923)
- Briggs, David R , Ph D Univ of Minnesota, Div of Agricultural Biochemistry, Univ Farm, St Paul *Prof of Agricultural Biochemistry, Chemist, Minn Agricultural Exper Station* (2, 1946)
- Briggs, George M , Ph D Univ of Minnesota, Univ Farm, St Paul *Asst Prof of Poultry Nutrition* (5, 1947)
- Brink, Frank Jr , Ph D Johns Hopkins Univ , Biological Labs , Baltimore 18, Md (1, 1942)
- Brinkhous, K M , M D Univ of North Carolina School of Medicine, Dept of Pathology, Chapel Hill *Prof of Pathology* (4, 1939)
- Britton, Sydney W , M D Univ of Virginia School of Medicine, Charlottesville *Prof of Physiology* (1, 1925)
- Brobeck, John R , M D , Ph D Yale Univ School of Medicine, New Haven, Conn *Asst Prof of Physiology* (1, 1943)
- Brodie, Bernard B , Ph D New York Univ Research Service, Goldwater Memorial Hospital, New York City 17 *Assoc Prof of Biochemistry* (2, 1940, 3, 1945)
- Brody, Samuel, Ph D Univ of Missouri College of Agriculture and Agricultural Experiment Station, Dairy Building, Columbia *Prof of Dairy Husbandry* (2, 1929, 5, 1933)
- Broh-Kahn, Robert H , M D May Inst for Med Research, Cincinnati, Ohio *Asst Dir* (1, 1948)
- Bromley, Reginald B , Ph D Johns Hopkins School of Medicine, Dept of Physiology, 710 N Washington St , Baltimore 5, Md *Prof of Physiology* (1, 1949)
- Bronfenbrenner, J J , Ph D , D P H Washington Univ School of Medicine, St Louis, Mo *Prof of Bacteriology and Immunology* (4, 1940, 6, 1918)
- Bronk, Detlev W , Ph D , Sc D Johns Hopkins Univ , Baltimore, Md *Pres , Chairman of Natl Research Council* (1, 1927)
- Brookes, Margaret C Hessler, Ph D Univ of Chicago, Chicago, Ill *Asst Prof , Dept of Home Economics* (5, 1935)
- Brookhart, John M , Ph D Univ of Oregon School of Medicine, Dept of Physiology, Portland *Assoc Prof* (1, 1946)
- Brooks, Chandler McCuskey, Ph D The Long Island College of Medicine, Dept of Physiology and Pharmacology, Brooklyn, N Y (1, 1934)
- Brooks, Clyde, Ph D , M D Univ Clinic, 2506 Ponce de Leon Blvd , Coral Gables, Fla (1, 1910, 3, 1912)
- Brooks, Matilda Moldenhauer, Ph D Univ of California, Dept of Physiology, Berkeley *Research Assoc in Biology* (1, 1923)
- Broun, Goronwy Owen, M D 1325 S Grand Blvd , St Louis, Mo *Prof of Internal Medicine, St Louis Univ* (4, 1927)
- Brown, Claude P , M D 1930 Chestnut St , Philadelphia Pa (6, 1913)
- Brown, Dugald E S , Ph D Bermuda Biological Station, St George's W , Bermuda (1, 1932)
- Brown, Ethan Allen, L R C P (Eng) , A R C S (London), 75 Bay State Rd , Boston, Mass *Lecturer in Medicine, Tufts College Med School, Physician-in-Chief, Allergy Clinic, Boston Dispensary* (6, 1946)
- Brown, Frank A , Jr , Ph D Northwestern Univ , Zoological Labs , Evanston, Ill *Assoc Prof of Zoology* (1, 1940)
- Brown, George B , Ph D Sloan-Kettering Inst for Cancer Research, 444 E 68th St , New York City 21 *Member, Asst Prof of Biochemistry, Cornell Univ Med College* (2, 1947)
- Brown, Gordon Campbell, Sc D School of Public Health, Ann Arbor, Mich *Assoc Prof of Epidemiology* (6, 1949)
- Brown, John B , Ph D Ohio State Univ , Columbus *Prof of Physiological Chemistry* (2, 1927, 5, 1934)
- Brown, R A , Ph D Parke Davis and Co , Research Labs , Detroit 32, Mich *Head of Div of Nutritional Research* (5, 1946)
- Brown, Rachel, Ph D 26 Buckingham Drive, Albany, N Y *Sr Biochemist, Div of Labs and Research, N Y State Dept of Health* (6, 1933)
- Brown, Robert V , Ph D Univ of Tennessee, Dept of Pharmacology, Memphis 3 *Assoc Prof* (1, 1945)
- Browne, J S L , M D , Ph D Royal Victoria Hospital, Univ Clinic, Montreal, Que , Canada *Asst Prof of Medicine, McGill Univ* (1, 1934)
- Brownell, Katharine A , Ph D Ohio State Univ , Dept of Physiology, Columbus *Research Assoc* (1, 1943)
- Brozek, Josef, Ph D Univ of Minnesota, Stadium South Tower, Minneapolis 14 *Assoc Prof , Lab of Physiological Hygiene, School of Public Health* (1, 1947)
- Brues, Austin M , M D Argonne National Labs , P O Box 5207, Chicago, Ill *Dir of Biology Div , Assoc Prof of Medicine and Instr of Radiobiology and Biophysics, Univ of Chicago* (1, 1940)
- Bruesch, S R , M D , Ph D Univ of Tennessee, Div of Anatomy, Memphis 3 *Prof of Anatomy* (1, 1949)
- Bruger, Maurice, M D , M Sc 301 E 20th St , New York City 3 *Assoc Prof of Medicine, New York Univ Post-Grad Med School, Chief, Div of Pathological Chemistry, New York University Hospital* (2, 1935, 5, 1935)
- Bruhn, John M , Ph D Med College of Alabama, Dept of Physiology, 620 S 20th St , Birmingham 5 *Prof of Physiology and Pharmacology* (1, 1939)
- Bruner, Harry Davis, M D , Ph D Med Div ORINS, Box 117, Oak Ridge, Tenn (3, 1945)
- Brunschwig, Alexander, M D Cornell Univ Med College, New York City *Prof of Clin Surgery, Attending Surgeon, Memorial Hosp* (4, 1937)

- Bryan, W Ray, Ph D Glen Rd , Rockville, Md
Principal Biologist, Natl Cancer Inst (1, 1934, 4, 1940)
- Buchanan, J William, Ph D Univ of Southern California, Alan Hancock Foundation, Los Angeles
Prof of Zoology (1, 1927)
- Buchanan, John M , Ph D Univ of Pennsylvania School of Medicine, Dept of Physiological Chemistry, Philadelphia
Asst Prof (2, 1949)
- Buchbinder, Lean, Ph D Dept of Health, 125 Worth St , New York City (6, 1934)
- Buchbinder, William C , M D 104 S Michigan Ave , Chicago, Ill
Asst Prof of Medicine, Northwestern Univ Med School, Assoc in Medicine, Michael Reese Hospital (1, 1940)
- Bucher, Gladys R , Ph D Univ of Illinois, Dept of Biology, Chicago Div , Navy Pier, Chicago 12 (1, 1946)
- Buckner, G Davis, Ph D Kentucky Agricultural Exper Station, Lexington
In Charge of Animal Nutrition (2, 1920)
- Bucy, Paul C , M D 4833 S Woodlawn Ave , Chicago, Ill
Prof of Neurology and Neurological Surgery, Univ of Illinois (1, 1933)
- Buddingh, G John, M D Louisiana State Univ School of Medicine, New Orleans
Prof of Microbiology (4, 1940)
- Bueding, Ernest, M D Western Reserve Univ School of Medicine, Dept of Pharmacology, Cleveland 6, Ohio
Assoc Prof (2, 1946, 3, 1949)
- Buell, Mary V , Ph D Univ of Wisconsin Enzyme Inst , Madison
Research Assoc (2, 1921)
- Bukantz, Samuel C , M D Washington Univ School of Medicine, St Louis 10, Mo
Research Asst in Medicine (6, 1943)
- Bulatao, Emilio, M D Univ of the Philippines, Manila, P I
Prof of Physiology and Biochemistry (1, 1924)
- Bull, Henry B , Ph D Northwestern Univ Med School, 303 E Chicago Ave , Chicago 11, Ill
Prof of Chemistry (2, 1937)
- Bullock, Theodore H , Ph D Univ of California, Los Angeles
Assoc Prof of Zoology (1, 1948)
- Bunde, Carl A , M D , Ph D Pitman-Moore Co , Indianapolis 6, Ind
Research Dir (1, 1943)
- Bunney, William Edward, Ph D E R Squibb and Sons, New Brunswick, N J
Vice Pres , Dir of Manufacturing Labs (6, 1931)
- Bunting, Charles H , M D 139 Armory St , Hamden, Conn
Prof Emeritus of Pathology, Univ of Wisconsin, Lecturer in Pathology, Yale Med School (4, 1913)
- Bunzell, H H , Ph D Box 44, General Post Office, New York City 1
Dir of Bunzell Labs (2, 1908)
- Burchell, Howard B , M D , Ph D 1506 Durand Court, Rochester, Minn
Instr in Medicine, Mayo Foundation, Consultant in Medicine, Mayo Clinic (1, 1942)
- Burdick, H O , Sc D Alfred Univ , Alfred, N Y
Prof of Biology (1, 1940)
- Burdon, Kenneth L , Ph D Baylor Univ College of Medicine, Houston, Tex
Prof of Bacteriology, Consultant, USPHS (6, 1936)
- Burk, Dean, Ph D Natl Cancer Inst , Bethesda, Md
Principal Chemist, USPHS (2, 1939)
- Burns, Edward L , M D Mercy Hospital, Toledo, Ohio
Pathologist (4, 1939)
- Burr, George O , Ph D Exper Station H S P A , Honolulu, Hawaii
Head of Dept of Biochemistry and Physiology (2, 1928, 5, 1933)
- Burris, Robert H , Ph D Univ of Wisconsin, Dept of Biochemistry, Madison 6
Assoc Prof of Biochemistry (2, 1946)
- Burrows, William, Ph D Univ of Chicago, Dept of Bacteriology and Parasitology, Chicago 37, Ill
Prof of Bacteriology (6, 1947)
- Burton, Alan C , Ph D Univ of Western Ontario, Dept of Med Research, London, Ontario, Canada
Asst Prof of Med Research (1, 1937)
- Burton-Opitz, Russell, M D , Ph D 218 Bridle Way, Palisade, N J
Attending Cardiologist, Lenox Hill Hospital, Attending Physician, Cumberland Hospital (1R, 1902, 2, 1906, 3R, 1919)
- Buschke, William H , M D Manhattan Eye, Ear and Throat Hospital, 210 E 64th St , New York City 21
Research Ophthalmologist, Head of Ayer Foundation Ophthalmic Research Lab (1, 1947)
- Bush, Milton T , Ph D Vanderbilt Univ School of Medicine, Nashville, Tenn
Assoc Prof of Pharmacology (3, 1938)
- Butler, G C , Ph D Univ of Toronto, Dept of Biochemistry, Toronto, Ont , Canada
Assoc Prof (2, 1949)
- Butler, Thomas C , M D Johns Hopkins School of Medicine, 710 N Washington St , Baltimore 5, Md
Assoc Prof of Pharmacology and Exper Therapeutics (3, 1938)
- Butt, Hugh R , M D Mayo Clinic, 102 Second Ave , S W , Rochester, Minn
Consultant in Medicine, Asst Prof of Medicine, Mayo Foundation (5, 1942)
- Butts, Joseph S , Ph D Oregon State College, Corvallis
Prof of Biochemistry and Head of Agricultural Chemistry (2, 1936, 5, 1936)
- Byers, Sanford O , Ph D 2200 Scott St , San Francisco 15, Calif
Research Biochemist, Harold Brunn Inst for Cardiovascular Research, Mount Zion Hospital (1, 1949)
- Cahen, Raymond L , Ph D , M D Maltbie Chemical Co , Research Labs , P O Box 270, Morristown, N J
Dir of Pharmacological Research (3, 1949)
- Cahill, William M , Ph D , M D 3320 Baldwin St , Los Angeles 31, Calif (2, 1940)
- Cajori, Florian A , Ph D Univ of Colorado Med School, Dept of Biochemistry, Denver 7
Asst Prof of Biochemistry (2, 1922, 5, 1933)
- Caldwell, Mary L , Ph D Columbia Univ , Dept of Chemistry, New York City
Prof of Chemistry (2, 1924, 5, 1933)

- Callison, Elizabeth C, M S U S Dept of Agriculture, Agricultural Research Station, Food and Nutrition Div, Bureau of Human Nutrition, Beltsville, Md *Nutrition Physiologist* (5, 1949)
- Calloway, Nathaniel Oglesby, Ph D, M D Univ of Illinois College of Medicine, 1819 W Polk St, Chicago 12 *Asst in Medicine* (3, 1945)
- Calvin, D Bailey, Ph D Univ of Texas Med Branch, Galveston *Prof of Biological Chemistry and Dean of Student and Curricular Affairs* (1, 1934, 2, 1939)
- Calvin, Melvin, Ph D Univ of California, Dept of Chemistry, Berkeley 4 *Prof of Chemistry* (2, 1949)
- Camunopetros, John, M D Hellenic Pasteur Inst, 103 Queen Sophie Ave, Athens, Greece *Chief of the Service of Exper Medicine* (6, 1946)
- Camp, Walter J R, M D, Ph D Univ of Illinois College of Medicine, 1853 W Polk St, Chicago, Ill *Prof of Pharmacology and Toxicology, State Toxicologist* (3, 1926)
- Campbell, Berry, Ph D Univ of Minnesota, Minneapolis 14 *Assoc Prof of Anatomy* (1, 1945)
- Campbell, Dan H, Ph D California Inst of Technology, Dept of Chemistry, Pasadena *Assoc Prof of Chemistry* (6, 1938)
- Campbell, James, Ph D Univ of Toronto, Toronto, Ont, Canada *Asst Prof of Physiology, Lt Comdr, (S B) R C N V R* (1, 1943)
- Campbell, Walter Ruggles, M D Univ of Toronto, 69 Madison Ave, Toronto, Ont, Canada *Assoc Prof of Medicine* (2, 1922)
- Cannan, R Keith, D Sc New York Univ College of Medicine, 477 First Ave, New York City *Prof of Chemistry* (2, 1931)
- Cannon, Paul R, M D, Ph D Univ of Chicago, Chicago, Ill *Prof of Pathology* (4, 1930, 6, 1929)
- Cantarow, Abraham, M D Jefferson Med College, Philadelphia 7, Pa *Prof of Biochemistry* (1, 1932, 3, 1935)
- Cantoni, G L, M D New York Univ College of Medicine, Dept of Pharmacology, New York City (3, 1945)
- Canzanelli, Attilio, M D Tufts College Med School, 416 Huntington Ave, Boston, Mass *Prof of Exper Physiology* (1, 1934)
- Carlson, A J, Ph D, M D Univ of Chicago, Hull Physiological Lab, Chicago, Ill *Prof Emeritus of Physiology* (1, 1904, 5, 1933)
- Carlson, Loren D, Ph D Univ of Washington School of Medicine, Dept of Physiology and Biophysics, Seattle 5 (1, 1945)
- Carmichael, Emmett B, Ph D Med College of Alabama, Dept of Biochemistry, Birmingham 5 *Prof and Head of Dept of Biochemistry* (1, 1931, 2, 1946)
- Carmichael, Leonard, Ph D Sc D Tufts College, Medford, Mass *Pres, Dir of Research Lab of Sensory Psychology and Physiology* (1, 1937)
- Carpenter, Frederick H, Ph D Univ of California, Dept of Biochemistry, Berkeley 4 *Asst Prof* (2, 1949)
- Carpenter, Thorne M, Ph D 27 Market St, Foxboro, Mass (1R, 1915, 2, 1909, 5, 1935)
- Carr, C Jelleff, Ph D Univ of Maryland School of Medicine, Baltimore *Assoc Prof of Pharmacology* (3, 1940)
- Carr, Jesse L, M D Univ of California Med School, Third and Parnassus Aves, San Francisco *Clin Prof of Pathology* (4, 1940)
- Carruthers, Christopher, Ph D Washington Univ School of Medicine, Dept of Anatomy, 4580 Scott Ave, St Louis 10, Mo *Research Assoc* (2, 1948)
- Carter, Herbert E, Ph D Univ of Illinois, 452 Noyes Lab, Urbana *Prof of Biochemistry* (2, 1937, 5, 1941)
- Cartland, George F, Ph D The Upjohn Co, Research Dept, Kalamazoo, Mich *Head of Antibiotics Research* (2, 1936)
- Cary, Charles A, S B U S Dept of Agriculture, Bureau of Dairy Industry, Dairy Research Lab, Beltsville, Md *Chief of Div of Nutrition and Physiology* (2, 1920)
- Casey, Albert Eugene, M D 1907 Wellington Rd, Birmingham 9, Ala *Pathologist, Baptist Hospital, Assoc Prof of Pathology, Med College of Alabama* (4, 1933)
- Cash, James Robert, M D Univ Hospital, Charlottesville, Va *Prof of Pathology, Univ of Virginia* (4, 1924)
- Cassidy, Harold G, Ph D Yale Univ, Sterling Chemical Lab, New Haven, Conn *Assoc Prof of Chemistry* (2, 1949)
- Castle, Edward S, Ph D Harvard Univ Biological Labs, Divinity Ave, Cambridge, Mass *Assoc Prof of General Physiology* (1, 1934)
- Castle, William B, M D Boston City Hospital, Boston, Mass *Prof of Medicine, Harvard Med School, Dir of Thorndike Memorial Lab* (4, 1942)
- Catchpole, Hubert Ralph, Ph D Univ of Chicago College of Medicine, 1853 W Polk St, Chicago 12, Ill *Research Assoc in Pathology* (1, 1941)
- Cathcart, E P, M D, D Sc Univ of Glasgow, Glasgow, Scotland *Dean of Univ* (5, 1935)
- Catron, Lloyd, M D City Hospital, Akron, Ohio *Pathologist* (4, 1939)
- Cattell, McKeen, Ph D, M D Cornell Univ Med College, 1300 York Ave, New York City *Prof of Pharmacology* (1, 1923, 3, 1924)
- Cavelti, Philip A, M D 672 S Westlake Ave, Los Angeles 34, Calif (6, 1947)
- Cederquist, Dena C, Ph D Michigan State College, School of Home Economics, East Lansing *Assoc Prof (Research) of Foods and Nutrition* (5, 1949)
- Cerecedo, Leopold R, Ph D Fordham Univ, New York City *Prof of Biochemistry* (2, 1931, 5, 1945)

- Chadwick, Leigh Edward**, Ph D Med Div, Army Chemical Center, Md (1, 1944)
- Chaikoff, I L**, Ph D, M D Univ of California, Berkeley *Assoc Prof of Physiology* (1, 1932)
- Chalkley, Harold W**, Ph D USPHS, Natl Insts of Health, Bethesda, Md *Sr Physiologist* (1, 1932)
- Chamberlain, W Edward**, M D Temple Univ Med School, Philadelphia, Pa *Prof of Radiology* (1, 1948)
- Chambers, Alfred H**, Ph D Univ of Vermont School of Medicine, Dept of Physiology, Burlington (1, 1946)
- Chambers, Leslie Addison**, Ph D Camp Detrick, Frederick, Md *Chief of Physical and Chemical Div* (1, 1940, 6, 1948)
- Chambers, William H**, Ph D Med Div, Army Chemical Center, Md *Chief of Toxicology Branch* (1, 1924, 5, 1933)
- Chandler, Caroline A**, M D Johns Hopkins School of Hygiene and Public Health, 615 N Wolfe St, Baltimore 5, Md *Asst Prof of Preventive Medicine* (6, 1938)
- Chandler, Joseph P**, Ph D Univ of Michigan Med School, Room G455, Univ Hosp, Ann Arbor *Asst Prof of Biological Chemistry, Biochemist, Univ Hosp* (2, 1944, 5, 1944)
- Chang, Min Cheuh**, Ph D Worcester Foundation, Shrewsbury, Mass *Assoc Fellow* (1, 1946)
- Chanutin, Alfred**, Ph D Box 1862, University Station, Charlottesville, Va *Prof of Biochemistry, Univ of Virginia* (2, 1925)
- Chapanis, Alphonse**, Ph D Johns Hopkins Univ, Baltimore, Md *Asst Prof of Psychology* (1, 1948)
- Chapman, C W**, Ph D Univ of Maryland, Baltimore *Prof of Pharmacology* (3, 1932)
- Chargaff, Erwin**, Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Assoc Prof of Biological Chemistry* (2, 1935)
- Charipper, Harry Adolph**, Ph D Washington Square College of Arts and Sciences, 100 Washington Square E, New York City *Prof and Chairman of Dept of Biology* (1, 1941)
- Chase, Aurin M**, Ph D Princeton Univ, Dept of Biology, Princeton, N J *Research Assoc, Asst Prof* (1, 1939)
- Chase, Harold F**, M D Univ of Virginia Hospital, Charlottesville (3, 1944)
- Chase, Merrill W**, Ph D Rockefeller Inst, 66th St and York Ave, New York City *Member of Staff* (6, 1938)
- Chasis, Herbert**, M D, Med Sc D 44 E 67th St, New York City *Asst Prof of Medicine, New York Univ College of Medicine* (1, 1941)
- Chatfield, Charlotte**, BS Food and Agriculture Organization of the United Nations, Washington, D C *Nutrition Officer* (5, 1941)
- Chatterjee, Hernendra Nath**, M D Calcutta Univ, Calcutta, India *Professor* (6, 1948)
- Cheldelin, Vernon H**, Ph D Univ of Wisconsin, Enzyme Inst, Madison (2, 1947, 5, 1946)
- Chen, Graham**, Sc D, M D Parke Davis and Co, Detroit, Mich (3, 1944)
- Chen, K K**, Ph D, M D Lilly Research Labs, Indianapolis, Ind *Dir of Pharmacological Research, Prof of Pharmacology, Indiana Univ School of Medicine* (1, 1929, 3, 1942)
- Cheney, Ralph H**, Sc D Brooklyn College, Biology Dept, Bedford Ave and Ave H, Brooklyn 10, N Y (3, 1934)
- Chenoweth, Maynard Burton**, M D Univ of Michigan Med School, Dept of Pharmacology, Ann Arbor *Assoc Prof of Pharmacology* (3, 1945)
- Chesley, Leon C**, Ph D Margaret Hague Maternity Hospital, 88 Clifton Place, Jersey City 4, N J *Chief Chemist* (1, 1949)
- Chesney, Alan M**, M D Johns Hopkins Hospital, Baltimore, Md *Dean of Johns Hopkins Med School, Assoc Prof of Medicine* (4, 1925)
- Child, George P**, Ph D Albany Med College, Albany 3, N Y *Asst Prof of Pharmacology* (3, 1949)
- Choucroun, Nine**, Dept of Public Health and Preventive Medicine, 1300 York Ave, New York City 22 *Research Assoc, Cornell Med College* (6, 1949)
- Chow, Bacon F**, Ph D Johns Hopkins Univ School of Hygiene, 615 N Wolfe St, Baltimore 14, Md *Assoc Prof of Biochemistry* (2, 1940, 5, 1948, 6, 1944)
- Christensen, Halvor N**, Ph D Tufts College Med School, Boston, Mass *Prof and Head of Dept of Biochemistry* (2, 1947)
- Christensen, L Royal**, Ph D New York Univ College of Medicine, Dept of Microbiology, 477 First Ave, New York City *Asst Prof* (6, 1942)
- Christian, Henry A**, M D 20 Chapel St, Brookline, Mass *Hersey Prof Emeritus of the Theory and Practice of Physics, Harvard Univ, Physician-in-Chief, Emeritus, Peter Bent Brigham Hospital* (4, 1924)
- Christman, Adam A**, Ph D Univ of Michigan Med School, Ann Arbor *Prof of Biological Chemistry* (2, 1929)
- Chu, Wei-chang**, M D 546 W 124th St, Apt 53, New York City (3, 1945)
- Clark, Ada R**, Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Assoc in Bacteriology, Teaching and Research* (6, 1936)
- Clark, Byron B**, Ph D Tufts College Med School, 416 Huntington Ave, Boston 15, Mass *Prof of Pharmacology* (3, 1940)
- Clark, Ernest D**, Ph D 826 Skinner Bldg, Seattle 1, Wash *Dir of the Labs, Northwest Branch, Natl Cannery Assoc* (2, 1912)

- Clark, George, Ph D Chicago Med School, Dept of Anatomy, 710 S Wolcott Ave, Chicago 12, Ill *Assoc Prof of Neuroanatomy* (1, 1943)
- Clark, Guy W, Ph D Lederle Labs, Inc, Pearl River, N Y *Tech Dir* (2, 1922)
- Clark, Janet Howell, Ph D Univ of Rochester, Anderson Hall, Rochester, N Y *Dean of the College for Women and Prof in the Div of Biological Sciences* (1, 1922)
- Clark, Paul F, Ph D Univ of Wisconsin Med School, Madison *Prof of Med Microbiology* (4, 1923, 6, 1928)
- Clark, William G, Ph D V A Center, Sawtelle and Wilshire Blvds, Los Angeles, Calif *Pharmacologist and Physiologist, Research Assoc, Univ of Calif School of Medicine* (1, 1942, 3, 1949)
- Clark, William Mansfield, Ph D Johns Hopkins Univ, Baltimore, Md *Prof of Physiological Chemistry* (2, 1920)
- Clarke, Hans Thacher, D Sc Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Prof of Biological Chemistry* (2, 1929)
- Clarke, Robert W Route 3, Helmwoods, Elizabethtown, Ky *Physiologist, Med Dept Field Research Lab, Fort Knox* (1, 1936)
- Clausen, Samuel Wolcott, M D Univ of Rochester School of Medicine, Rochester, N Y *Prof of Pediatrics* (2, 1922)
- Cleghorn, Robert Allen, M D, D Sc McGill Univ, Dept of Psychiatry, Montreal, Quebec, Canada (1, 1937)
- Clowes, George Henry Alexander, Ph D Eli Lilly & Co, Indianapolis 6, Ind *Dir of Research Emeritus* (2, 1914, 6, 1919)
- Coburn, Alvin F, M D Rheumatic Fever Research Inst, Chicago, Ill *Director* (6, 1948)
- Code, Charles F, Ph D, M D Mayo Foundation, Rochester, Minn *Prof of Physiology* (1, 1939)
- Coffey, Julia M, A B Div of Labs and Research, New York State Dept of Health, Albany *Assoc Bacteriologist* (6, 1937)
- Coghill, Robert D, Ph D Abbott Labs, N Chicago, Ill *Dir of Research* (2, 1932)
- Cohen, Barnett, Ph D Johns Hopkins Univ School of Medicine, 710 N Washington St, Baltimore 5, Md *Assoc Prof of Physiological Chemistry* (2, 1935)
- Cohen, Philip P, Ph D, M D Univ of Wisconsin, Service Memorial Inst, Madison *Prof of Physiological Chemistry* (2, 1941)
- Cohen, Saul L, Ph D Univ of Minnesota, 207 Millard Hall, Minneapolis *Asst Prof of Physiological Chemistry* (2, 1948)
- Cohen, Seymour S, Ph D Children's Hospital, 1840 Bainbridge St, Philadelphia, Pa *Asst Prof of Physiological Chemistry, Univ of Pennsylvania School of Medicine* (2, 1946)
- Cohen, Sophia M, B S New York State Dept of Health, Div of Labs and Research, Albany *Sr Bacteriologist* (6, 1938)
- Cohn, Alfred E, M D 300 Central Park W, New York City *Member of Rockefeller Inst for Med Research* (1R, 1911, 3, 1913)
- Cohn, Clarence, M D Michael Reese Hospital, Med Research Inst, Chicago, Ill *Dir of Dept of Biochemistry* (1, 1948)
- Cohn, Edwin J, Ph D 183 Brattle St, Cambridge, Mass *Prof of Biological Chemistry, Harvard Med School, Univ Prof, Harvard Univ* (1, 1919, 2, 1919)
- Cohn, Mildred, Ph D Washington Univ School of Medicine, Dept of Biochemistry, 4580 Scott Ave, St Louis 10, Mo *Research Assoc* (2, 1949)
- Cohn, Waldo E, Ph D Oak Ridge Natl Lab, Biology Div, Oak Ridge, Tenn *Biochemist* (2, 1944)
- Cole, Harold H, Ph D Univ of California, College of Agriculture, Div of Animal Husbandry, Davis *Professor* (1, 1947)
- Cole, Harold N, Ph B, M D 1352 Hanna Bldg, Cleveland, Ohio *Clin Prof of Dermatology and Syphilology, Western Reserve Univ* (3, 1925)
- Cole, Kenneth S, Ph D Univ of Chicago, Inst of Radiobiology and Biophysics, Chicago 37, Ill *Prof of Biophysics* (1, 1934)
- Cole, Milton B, M.D 10616 Euclid Ave, Cleveland, Ohio *Dir of Asthma, Hay Fever and Allergy Foundation* (6, 1931)
- Cole, Versa V, Ph D, M D Indiana Univ School of Medicine, 1040-1232 W Michigan St, Indianapolis *Assoc Prof of Pharmacology* (3, 1941)
- Collett, Mary Elizabeth, Ph D Western Reserve Univ, Mather College, Cleveland, Ohio *Assoc Prof of Biology* (1, 1921)
- Collier, H Bruce, Ph D Univ of Alberta, Dept of Biochemistry, Edmonton, Alta, Canada *Prof of Biochemistry* (2, 1944)
- Collings, William Doyne, Ph D Michigan State College, Dept of Physiology, East Lansing (1, 1944)
- Collins, Dean A, Ph D, M D Temple Univ School of Medicine, 3400 N Broad St, Philadelphia 40, Pa *Prof of Pharmacology* (1, 1938)
- Collins, Russell J, A M, M D St John, New Brunswick, Canada *Med Superintendent of St John Tuberculosis Hospital* (3, 1915)
- Collip, J B, Ph D M D Univ of Western Ontario, R R 3, London, Ontario, Canada *Dean of Medicine and Prof of Med Research* (1, 1920, 2, 1920)
- Colowick, Sidney P, Ph D Univ of Illinois College of Medicine, Dept of Biological Chemistry, 1853 W Polk St, Chicago 12 *Assoc Prof* (2, 1944)
- Coman, Dale R, M D Univ of Pennsylvania School of Medicine, McManes Lab of Pathol-

- ogy, Philadelphia *Assoc Prof of Pathology* (4, 1939)
- Comroe, Julius H, Jr**, M D Univ of Pennsylvania Grad School of Medicine, Philadelphia *Prof of Physiology and Pharmacology* (1, 1943, 3, 1939)
- Conant, James B**, Ph D Harvard Univ, 5 Univ Hall, Cambridge, Mass *President* (2, 1932)
- Concepcion, Isabelo**, M D 589 Zamora, Pasay, Rizal, Philippines Faculty of Medicine, Univ Santo Tomas, Manila, Philippines *Prof of Biochemistry and Nutrition* (1, 1919)
- Conklin, Ruth E**, Ph D Vassar College, Poughkeepsie, N Y *Prof of Physiology* (1, 1940)
- Conn, Jerome W**, M D Univ of Michigan Med School, Ann Arbor *Assoc Prof of Internal Med* (5, 1942)
- Consolazio, William V**, BS Office of Naval Research, 23 Argyle Ave, Garrett Park, Md *Head of Biochemistry Branch, Biological Sciences Div* (2, 1949)
- Cook, Donald Hunter**, Ph D Univ of Miami, Coral Gables 34, Fla *Prof of Chemistry* (2, 1929)
- Cooke, Robert A**, A M, M D 60 E 58th St, New York City *Dir of Dept of Allergy, Roosevelt Hospital* (6, 1920)
- Coolidge, Thomas B**, M D, Ph D Univ of Chicago, Abbot Hall, Chicago 37, Ill *Assoc Prof, Dept of Biochemistry and Walter G Zoller Memorial Dental Clinic* (2, 1942)
- Coon, Julius M**, Ph D, M D Univ of Chicago, Dept of Pharmacology, Chicago 37, Ill *Assoc Prof of Pharmacology, Dir of Toxicity Lab* (3, 1941)
- Coons, Callie Mae**, Ph D U S Dept of Agriculture, Bureau of Human Nutrition and Home Economics, Washington, D C *Asst Chief* (5, 1933)
- Cooper, Merlin L**, M D Children's Hospital Research Foundation, Elland Ave and Bethesda, Cincinnati 29, Ohio *Assoc Prof of Bacteriology, Asst Prof of Pediatrics, Univ of Cincinnati College of Medicine* (6, 1949)
- Cooper, Ruth S** Princeton Univ, Dept of Biology, Princeton, N J (6, 1949)
- Cope, Otis M**, M D Univ of Florida, School of Pharmacy, Gainesville (1, 1929)
- Copley, Alfred Lewin**, M D New York Univ, Dept of Biology, Lab of Cellular Physiology, Washington Square, New York City 3 *Research Assoc in Medicine, Asst Clin Prof, New York Med College* (1, 1944)
- Corbin, Kendall B**, M D 919 80th St, S W, Rochester, Minn *Consultant in Neurology, Mayo Clinic, Prof of Neuroanatomy, Mayo Foundation* (1, 1941)
- Corcoran, Arthur Curtis**, C M, M D Cleveland Clinic Foundation, Cleveland 6, Ohio (1, 1940)
- Corey, Edward Lyman**, Ph D Univ of Virginia School of Medicine, University, Va *Asst Prof of Physiology* (1, 1931)
- Cori, Carl F**, M D Washington Univ School of Medicine, Kingshighway and Euclid Ave, St Louis 10, Mo *Prof of Biochemistry* (2, 1925, 3, 1934)
- Cori, Gerty T**, M D Washington Univ School of Medicine, St Louis 10, Mo *Prof of Biochemistry* (2, 1927, 3, 1934)
- Corley, Ralph Conner**, Ph D Purdue Univ, Dept of Chemistry, Lafayette, Ind *Prof of Biochemistry* (2, 1927)
- Corper, Harry J**, M D, Ph D 1295 Clermont St, Denver 7, Colo *Dir of Research, Natl Jewish Hospital and Univ of Colorado School of Medicine* (2, 1912)
- Corson, Samuel A**, Ph D Howard Univ School of Medicine, Dept of Physiology, Washington, D C (1, 1943)
- Cotts, Gerhard K**, M D Lynchburg State Colony, Lynchburg, Va *Clinical Dir* (3, 1937)
- Co Tui, Frank**, M D New York Univ College of Medicine, 477 First Ave, New York City *Assoc Prof of Exper Surgery* (3, 1931)
- Cournand, Andre Frederic**, M D Chest Service, Bellevue Hospital, C D Building, 1st Ave at 28th St, New York City *Assoc Prof of Medicine, College of Physicians and Surgeons, Columbia Univ* (1, 1944)
- Cowgill, George Raymond**, Ph D Yale Univ, Nutrition Lab, 333 Cedar St, New Haven 11, Conn *Prof of Nutrition, Dept of Physiological Chemistry* (1, 1923, 2, 1922, 5, 1933)
- Cox, Alvin J, Jr**, M D Stanford Univ School of Medicine, Dept of Pathology, 2398 Sacramento St, San Francisco 15, Calif *Prof of Pathology* (4, 1949)
- Cox, Gerald J**, Ph D Univ of Pittsburgh School of Dentistry, Pittsburgh 13, Pa *Prof of Dental Research* (2, 1930, 5, 1935)
- Cox, Herald R**, Sc D Lederle Labs Div, Pearl River, N Y *Dir, Viral and Rickettsial Research* (6, 1946)
- Cox, Warren M, Jr**, Ph D Mead Johnson & Co, Evansville, Ind *Dir of Research* (2, 1935, 5, 1945)
- Craig, Francis Northrop**, Ph D Med Div, Army Chemical Center, Md *Physiologist* (1, 1946)
- Craig, L C**, Ph D Rockefeller Inst for Med Research, 66th St and York Ave, New York City 21 *Assoc Member* (2, 1938)
- Crampton, E W**, Ph D McGill Univ, Macdonald College, Montreal, Quebec, Canada *Prof of Nutrition* (5, 1940)
- Crandall, Lathan A, Jr**, M D, Ph D Miles Labs, Inc, Elkhart, Ind (1, 1930, 5, 1940)
- Cranston, Elizabeth M**, Ph D Univ of Minnesota Med School, Dept of Pharmacology, Minneapolis 14 *Instructor* (3, 1946)

- Cravens, W W , Ph D Univ of Wisconsin, Poultry Dept , Madison *Assoc Prof of Poultry Husbandry* (5, 1947)
- Craver, Bradford N , Ph D , M D Ciba Pharmaceutical Products, Inc , Lafayette Park, Summit, N J *Sr Pharmacologist* (3, 1946)
- Crawford, Madeleine Field, Ph D 9 High Rock St , Needham, Mass *Assoc in Physiology, Harvard School of Public Health* (1, 1933)
- Crescitelli, Frederick, Ph D Univ of California, Dept of Zoology, Los Angeles *Physiologist* (1, 1946)
- Cressey, Norman L , M D Veterans Hospital, Newington, Conn (6, 1943)
- Cretcher, Leonard H , Ph D Univ of Pittsburgh, Mellon Inst of Industrial Research, Pittsburgh Pa *Asst Dir and Head of Dept of Research in Pure Chemistry* (2, 1930)
- Crider, Joseph O , M D Jefferson Med College, Philadelphia, Pa *Prof of Physiology* (1, 1935)
- Crisler, George R , Ph D , M D 157 E New England Ave , Winter Park, Fla (1, 1930)
- Crismon, Jefferson Martineau, M D Stanford Univ , Calif *Assoc Prof of Physiology* (1, 1944)
- Crittenden, Phoebe J , Ph D Goucher College, Dept of Physiology and Hygiene, Towson 4, Md (1, 1937, 3, 1937)
- Crozier, William J , Ph D Harvard Univ , Biological Labs , Cambridge, Mass *Prof of General Physiology* (1, 1928)
- Csonka, F A , Ph D U S Dept of Agriculture, Bureau of Human Nutrition and Home Economics, Beltsville, Md *Sr Chemist* (2, 1924)
- Cullen, Stuart C , M D Univ Hospital, Iowa City, Iowa *Asst Prof of Surgery-Anesthesia* (3, 1944)
- Cunningham, Raymond W , Ph D Lederle Labs , Inc , Pearl River, N Y *Head, Pharmacology Research* (3, 1941)
- Cunningham, Robert Sydney, M D , Sc D Albany Med College, Albany, N Y *Prof of Anatomy and Dean* (1, 1923)
- Cureton, Thomas Kirk, Jr , Ph D Univ of Illinois, School of Physical Education, Urbana *Assoc Prof of Physical Education* (1, 1946)
- Curnen, Edward C , M D Yale Univ School of Medicine, New Haven 11, Conn (6, 1941)
- Curtis, George Morris, Ph D , M D Ohio State Univ , Kinsman Hall, Columbus *Prof of Surgery, Chairman, Dept of Research Surgery* (1, 1933, 4, 1933)
- Curtis, Howard J , Ph D Vanderbilt Univ School of Medicine, Nashville 4, Tenn *Prof of Physiology* (1, 1940)
- Cutting, Reginald A , M D , Ph D Georgetown Univ School of Medicine, 3900 Reservoir Rd , N W , Washington, D C *Prof of Physiology and Dir of the Dept* (1, 1939)
- Cutting, Windsor C , M D Stanford Univ School of Medicine, San Francisco, Calif *Prof of Therapeutics* (3, 1939)
- Daft, Floyd Shelton, Ph D Natl Insts of Health, Bethesda, Md *Chief, Biochemistry and Nutrition Lab , Asst Dir , Exper Biology and Medicine Inst* (2, 1949, 5, 1941)
- Daggs, Ray Gilbert, Ph D Med Dept , Field Research Lab , Fort Knox, Ky *Dir of Research* (1, 1935, 5, 1933)
- Dakin, Henry D , D Sc , Ph.D Scarborough-on-Hudson, N Y (2, 1906)
- Dalldorf, Gilbert, M D New York State Dept of Health, Albany *Dir , Div of Labs and Research* (4, 1947)
- Dalton, Albert J , Ph D Natl Cancer Inst , Bethesda, Md *Principal Cytologist* (4, 1942)
- Dam, Henrik, Ph D Biologisk Afdeling Danmarks Tekniske Højskole, Østervoldgade 10 L, Copenhagen, K, Denmark *Professor* (2, 1944, 5, 1943)
- D'Amour, Fred E , Ph D 2311 S Josephine St , Denver, Colo *Assoc Prof , Dept of Zoology, Univ of Denver* (1, 1934)
- D'Amour, Marie C , Ph D , M D 2311 S Josephine St , Denver, Colo (1, 1934)
- D'Angelo, Savino A , Ph D New York Univ , Dept of Biology, Washington Square, New York City 3 *Asst Prof of Biology* (1, 1947)
- Daniel, Louise J , Ph D Cornell Univ , Savage Hall, Ithaca, N Y *Asst Prof of Biochemistry* (2, 1949)
- Daniels, Amy L , Ph D 720 N Van Buren St , Iowa City, Iowa (2, 1919, 5, 1933)
- Danielson, Irvin S , Ph D Lederle Labs , Amer Cyanamid Co , 18 Bogert Ave , Pearl River, N Y *Head, Biol Production, Animal Industry Section* (2, 1937)
- Danowski, T S , M D Univ of Pittsburgh School of Medicine, Pittsburgh, Pa *Renzhausen Prof of Research Medicine* (1, 1947)
- Darby, William J , M D , Ph D Vanderbilt Univ School of Medicine, Div of Nutrition, Nashville, Tenn *Prof of Biochemistry, Asst Prof of Medicine* (2, 1949, 5, 1945)
- Darling, Robert Croly, M D 157 Glenwood Ave , Leonia, N J Columbia Univ College of Physicians and Surgeons, Dept of Medicine, New York City 32 (1, 1944)
- Darrow, Chester W , Ph D Inst for Juvenile Research, 907 S Wolcott St , Chicago, Ill *Research Psychologist, Assoc in Physiology, Univ of Illinois College of Medicine* (1, 1937)
- Darrow, Daniel Cady, M D Yale Univ School of Medicine, New Haven, Conn *Prof of Pediatrics* (2, 1936)
- Daubert, B F , Ph D Univ of Pittsburgh, 220 Alumni Hall, Dept of Chemistry, Pittsburgh 13, Pa *Research Prof and Research Admin* (2, 1947)
- Davenport, Horace Willard, Ph D Univ of Utah,

- Dept of Physiology, Salt Lake City 1 (1, 1942)
- David, Norman Austin**, M D Univ of Oregon Med School, Portland *Prof of Pharmacology* (3, 1934)
- Davidsohn, Israel**, M D Mount Sinai Hospital, Chicago, Ill *Pathologist and Dir of Labs, Chicago Med School, Prof of Pathology and Chairman of Dept* (4, 1939, 6, 1929)
- Davidson, Charles S**, M D Boston City Hospital, Thorndike Memorial Lab, Boston 18, Mass *Assoc in Medicine, Harvard Med School, Assoc Dir, 2nd and 4th Med Services, Boston City Hospital* (5, 1949)
- Davies, Philip W**, Ph D Johns Hopkins Univ, Biophysics Dept, Baltimore 18, Md (1, 1948)
- Davis, Bernard D**, M D Cornell Univ Med College, New York City *Research Assoc, Surgeon, USPHS* (6, 1948)
- Davis, George Kelso**, Ph D Nutrition Lab, Animal Industry Dept, Agricultural Exper Station, Gainesville, Fla *Nutritional Technologist and Biochemist, Prof of Nutrition, Univ of Florida, Florida Agricultural Exper Station* (5, 1944)
- Davis, Hallowell**, M D Central Inst for the Deaf, 818 S Kingshighway, St Louis 10, Mo (1, 1925)
- Davis, Harry A**, M D College of Med Evangelists, Dept of Surgery, 2007 Wilshire Blvd, Los Angeles 5, Calif (4, 1944)
- Davis, John Emerson**, Ph D Univ of Arkansas School of Medicine, Little Rock *Prof of Pharmacology and Physiology* (1, 1941, 3, 1941)
- Dawson, Charles R**, Ph D Columbia Univ, 411 Havemeyer Hall, New York City 27 *Assoc Prof of Chemistry* (2, 1946)
- Dawson, James Robertson, Jr**, M D Univ of Minnesota School of Medicine, Minneapolis 14 *Prof of Pathology* (4, 1940)
- Day, Harry G**, D Sc Indiana Univ, Dept of Chemistry, Bloomington *Assoc Prof* (2, 1948, 5, 1940)
- Day, Paul L**, Ph D Univ of Arkansas School of Medicine, Little Rock *Prof of Biochemistry* (2, 1934, 5, 1933)
- De, N N**, M B Indian Inst of Science, P O Malleswaram, Bangalore, India *Asst Prof of Pharmacology* (3, 1948)
- Dearborn, Earl H**, Ph D Johns Hopkins Univ School of Medicine, 800 N Washington St, Baltimore 5, Md *Instr in Pharmacology and Exper Therapeutics* (3, 1946)
- de Beer, Edwin J**, Ph D The Wellcome Research Labs, Tuckahoe, N Y *Asst Dir of Research* (3, 1944)
- De Bodo, Richard C**, M D 477 First Ave, New York City *Assoc Prof of Pharmacology, New York Univ College of Medicine* (1, 1932, 3, 1931)
- De Boer, Benjamin**, Ph D St Louis Univ School of Medicine, 1402 S Grand Blvd, St Louis 4, Mo *Asst Prof of Pharmacology* (1, 1947, 3, 1948)
- DeEds, Floyd**, Ph D 344 Santa Ana Ave, San Francisco, Calif *Principal Pharmacologist, Western Regional Research Lab, Albany, Calif* (2, 1937, 3, 1927)
- Defandorf, James Holmes**, Ph D Office of the Chief of the Chemical Warfare Service, Washington, D C *Colonel, Sn C* (3, 1940)
- de Gara, Paul F**, M D 200 Pinehurst Ave, New York City *Instr in Pathology, Cornell Univ Med College, Physician, New York Hospital* (6, 1941)
- DeGraff, Arthur C**, M D New York Univ College of Medicine, New York City *Prof of Therapeutics* (3, 1937)
- de Gutierrez-Mahoney, C G**, M D St Vincent's Hospital, New York City *Dir, Neurological Div and Neurosurgeon-in-Chief* (1, 1940, 4, 1941)
- Deichmann, William B**, Ph D Albany Med College, Albany, N Y *Assoc Prof and Head, Div of Pharmacology* (3, 1941)
- del Pozo, E C**, M D Medellin 196, Mexico, D.F., Mexico (1, 1943)
- Dempsey, Edward W**, Ph D Harvard Med School, Boston, Mass *Assoc Prof of Anatomy* (1, 1940)
- Denslow, J S**, D O Kirksville College of Osteopathy, Still Memorial Research Trust, Kirksville, Mo *Researcher* (1, 1949)
- Denstedt, Orville F**, Ph D McGill Univ, Dept of Biochemistry, Montreal, Que, Canada *Assoc Prof* (2, 1948)
- Derbyshire, Arthur J**, Ph D Harper Hospital, EEG Dept, Detroit, Mich (1, 1939)
- de Savitsch, Eugene**, M D Suite 24, 1150 Connecticut Ave, Washington, D C *Clinical Instr in Surgery, Georgetown Univ School of Medicine, Surgeon, Doctors Hospital* (4, 1934)
- Dettwiler, Herman A**, Ph D Eli Lilly and Co, Indianapolis, Ind *Asst Dir, Biological Div* (6, 1946)
- Deuel, Harry J, Jr**, Ph D Univ of Southern California, Los Angeles *Prof of Biochemistry and Dean of Grad School* (1, 1928, 2, 1924, 5, 1933)
- Deulofeu, Venancio D** Chem Casilla Correo 2539, Buenos Aires, Argentina *Prof of Organic Chemistry, Univ of Buenos Aires* (2, 1942)
- Deutsch, Harold F**, Ph D Univ of Wisconsin, Dept of Physiological Chemistry, Madison 6 *Assoc Prof* (2, 1948)
- Dewey, Virginia C**, Ph D Amherst College, Biological Lab, Amherst, Mass *Research Assoc, Dept of Biology* (2, 1949)

- Dey, Frederick L, Ph D, M D Box 11, Submarine Base, New London, Conn *Lt (j g)*, *U S N R* (1, 1945)
- Deyrup, Ingrith J, Ph D Barnard College, Columbia Univ, Dept of Zoology, New York City 27 *Asst Prof* (1, 1949)
- Dickison, H L, Ph D Bristol Labs, Inc, Bldg 6, Syracuse 1, N Y (3, 1946)
- Dieckmann, William J, M D The Chicago Lying-In Hospital, 5841 Maryland Ave, Chicago 37, Ill *Mary Campan Ryerson Prof and Chairman of Dept of Obstetrics and Gynecology, Univ of Chicago* (3, 1947)
- Dienes, Louis, M D Massachusetts General Hospital, Boston *Bacteriologist* (6, 1924)
- Dill, David Bruce, Ph D Med Div, Army Chemical Center, Md *Scientific Dir* (1, 1941, 2, 1927, 5, 1936)
- Dille, James M, Ph D, M D Univ of Washington School of Medicine, Seattle 5 *Prof of Pharmacology, Asst Dean* (3, 1939)
- Dillon, Robert T, Ph D G D Searle and Co, Box 5110, Chicago 80, Ill *Head, Analytical Div* (2, 1934)
- Dingle, John H, Sc D, M D Western Reserve Univ School of Medicine, Cleveland 6, Ohio *Prof of Preventive Medicine* (6, 1941)
- Di Palma, Joseph R, M D Long Island College of Medicine, 350 Henry St, Brooklyn, N Y *Assoc in Physiology* (1, 1943)
- Dische, Zacharias, M D Columbia Univ College of Physicians and Surgeons, Dept of Biochemistry, 630 W 168th St, New York City 32 (2, 1944)
- Dixon, Harold M, M D Army Inst of Pathology, Washington 25, D C (4, 1936)
- Doan, Charles A, M D Ohio State Univ College of Medicine, Columbus *Dean, Prof of Medicine* (4, 1928)
- Dobriner, Konrad, M D Sloan-Kettering Inst, 444 E 68th St, New York City 21 *Member* (2, 1946)
- Dodds, Mary L, Ph D Pennsylvania State College, State College *Prof, Foods and Nutrition Research* (5, 1948)
- Dohan, F Curtis, M D 80 Princeton Rd, Cnywyd, Pa *Fellow, George S Cox Med Research Inst, Assoc in Medicine, Univ of Pennsylvania* (1, 1941)
- Doisy Edward A, Ph D St Louis Univ School of Medicine, St Louis 4, Mo *Prof of Biological Chemistry* (2, 1920)
- Dolman, C E, D P H, Ph D Univ of British Columbia, Vancouver, B C, Canada *Head of Dept of Bacteriology and Preventive Medicine* (6, 1947)
- Dominguez, Rafael, M D Western Reserve Univ, Cleveland, Ohio *Assoc in Pathology, Dir of Labs and Research, St Luke's Hospital* (1, 1935)
- Donahue, D D, D Sc Natl Insts of Health, Div of Industrial Hygiene, Bethesda, Md *Physiologist, Toxicology Section* (3, 1941)
- Dorfman, Albert, Ph D, M D Univ of Chicago, Dept of Pediatrics, Chicago, Ill *Asst Prof* (2, 1948)
- Dorfman, Ralph I, Ph D Western Reserve Univ School of Medicine, Dept of Biochemistry, Cleveland, Ohio *Asst Prof of Biochemistry* (2, 1940)
- Dotti, Louis Basil, Ph D St Luke's Hospital, Amsterdam Ave and 113th St, New York City *Chemist, Lecturer in Physiology and Biochemistry, New York Med College* (1, 1937)
- Doty, J Roy, Ph D American Dental Assoc, 222 E Superior St, Chicago, Ill *Sr Chemist* (2, 1941)
- Doudoroff, Michael, Ph D Univ of California, Dept of Bacteriology, 3519 Life Sciences Bldg, Berkeley 4 *Assoc Prof* (2, 1946)
- Dounce, Alexander L, Ph D Strong Memorial Hospital, 260 Crittenden Blvd, Rochester N Y *Instr in Biochemistry, Univ of Rochester School of Medicine and Dentistry* (2, 1944)
- Doupe, Joseph, M D Medical College, Dept of Physiology and Med Research, Bannatyne and Emily, Winnipeg, Manitoba, Canada *Professor* (1, 1949)
- Dow, Philip, Ph D Univ of Georgia School of Medicine, Augusta *Assoc Prof of Physiology* (1, 1939)
- Dow, Robert S, M D, Ph D Univ of Oregon Med School, Portland, *Assoc Prof of Anatomy* (1, 1940)
- Downs, Ardrey W, M D, D Sc Univ of Alberta, Edmonton, Alberta, Canada *Prof of Physiology and Pharmacology* (1, 1917)
- Downs, Cora M, Ph D 1625 Alabama St, Lawrence, Kan (6, 1929)
- Doyle, William Lewis, Ph D 930 E 58th St, Chicago 37, Ill *Assoc Prof of Anatomy, Univ of Chicago* (1, 1946)
- Drabkin, David L, M D Univ of Pennsylvania Grad School of Medicine, Philadelphia 4 *Prof and Chairman of Dept of Physiological Chemistry* (2, 1928, 5, 1934)
- Dragstedt, Carl A, Ph D, M D Northwestern Univ Med School, 303 E Chicago Ave, Chicago, Ill *Prof of Pharmacology* (1, 1928, 3, 1932)
- Dragstedt, Lester R, M D, Ph D Univ of Chicago, Chicago, Ill *Prof of Surgery* (1, 1920)
- Draize, J H, Ph D Food and Drug Admin, Div of Pharmacology, Federal Security Agency, Washington, D C *Pharmacologist* (3, 1940)
- Drake, T G H, M B Univ of Toronto, Toronto, Canada *Jr Demonstrator in Pediatrics, Dept*

- of Medicine, Assoc Dir, Research Lab, Hospital for Sick Children (5, 1936)
- Draper, William B**, M Sc, M D Univ of Colorado School of Medicine, 4200 E 9th Ave, Denver Assoc Prof of Physiology and Pharmacology (1, 1947, 3, 1938)
- Dreisbach, Robert H**, Ph D, M D Stanford Univ School of Medicine, San Francisco 15, Calif Asst Prof (3, 1945)
- Dreyer, Nicholas Bernard**, M A Univ of Vermont School of Medicine, Burlington Assoc Prof of Physiology and Pharmacology (3, 1942)
- Drill, Victor Alexander**, Ph D, M D Wayne Univ College of Medicine, Detroit 26, Mich Prof of Pharmacology (1, 1943, 3, 1946)
- Drinker, Cecil K**, M D P O Box 502, Falmouth, Mass (1, 1915)
- Dripps, Robert D**, M D Univ of Pennsylvania School of Medicine, Philadelphia 4 Prof of Anesthesiology, Lecturer in Pharmacology (1, 1947, 3, 1946)
- Driver, Robert L**, M D, Ph D Humboldt, Tennessee (1, 1945, 3, 1947)
- Drury, Douglas R**, M D Univ of Southern California, Los Angeles Prof of Physiology (1, 1932)
- Dubin, Harry E**, Ph D 11 W 42nd St, New York City 18 President, H E Dubin Labs, Inc (2, 1925)
- Dubin, Isadore N**, M D Natl Cancer Inst, Bethesda, Md (4, 1947)
- Dubnoff, Jacob W**, Ph D 1201 E California St, Pasadena 4, Calif Sr Research Fellow, California Inst of Technology (2, 1946)
- DuBois, Eugene F**, M D Cornell Univ Med School, 1300 York Ave, New York City Prof and Head of Dept of Physiology and Biophysics, Attending Physician, New York Hospital (1, 1913, 3, 1921, 5, 1935)
- Du Bois, Kenneth P**, Ph D Univ of Chicago, Dept of Pharmacology, Chicago 37, Ill Asst Prof of Pharmacology (3, 1946)
- Dubos, Rene J**, Ph D, D Sc Rockefeller Inst for Med Research, 66th St and York Ave, New York City Head of Dept of Bacteriology (6, 1938)
- Dugal, L Paul**, Ph D Laval Univ Med School, Research Dept on Acclimatization, Quebec City, Canada Research Prof and Head of Dept, Assoc Dir of Inst of Hygiene (1, 1947)
- Dukes, H H**, D V.M, M S Cornell Univ, New York State Veterinary College, Ithaca Prof of Veterinary Physiology (1, 1934)
- Dulaney, Anna D**, Ph D Univ of Tennessee, Pathological Inst, Memphis Assoc Prof of Bacteriology, Med School (6, 1924)
- Dumke, Paul Rudolph**, M D Clinical Research Section, Med Research Lab, Army Chemical Center, Md Instr in Pharmacology, Univ of Pennsylvania, Captain, M C (3, 1942)
- Dunlap, Charles E**, M D Tulane Univ of Louisiana, 1430 Tulane Ave, New Orleans Prof of Pathology (4, 1942)
- Dunn, Max Shaw**, Ph D Univ of California, Los Angeles Prof of Chemistry (2, 1933)
- Dunn, Thelma Brumfield**, M D Natl Cancer Inst, Bethesda, Md Pathologist (4, 1945)
- Durlacher, Stanley H** Med Div, Army Chemical Center, Md Chief, Section on Pathology (1, 1949)
- Dury, Abraham**, Ph D Dorn Lab for Med Research, Bradford Clinic, Bennett at Pleasant St, Bradford, Pa Asst Dir of Research (1, 1948)
- Dutcher, James D**, Ph D Squibb Inst for Med Research, New Brunswick, N J Research Assoc, Div of Organic Chemistry (2, 1946)
- Dutcher, R Adams**, D Sc Pennsylvania State College, State College Prof and Head of Dept of Agricultural Biochemistry (2, 1920, 5, 1933)
- Duval, Charles Warren**, M D Sacred Heart Hospital, Pensacola, Fla Prof Emeritus of Pathology and Bacteriology, Tulane Univ (4, 1913)
- du Vigneaud, Vincent**, Ph D Cornell Univ Med College, 1300 York Ave, New York City 21 Prof of Biochemistry (2, 1929, 5, 1934)
- Dworkin, Simon**, D D S, M D McGill Univ, Biology Building, Montreal, Quebec, Canada Lecturer in Physiology, Faculty of Medicine (1, 1931)
- Dye, J A**, Ph D Cornell Univ, James Law Hall Ithaca, N Y Prof of Physiology (1, 1929)
- Dye, Marie**, Ph D Michigan State College, East Lansing Dean, School of Home Economics (2, 1929, 5, 1933)
- Dyer, Helen M**, Ph D Natl Cancer Inst Bethesda, Md Biochemist (2, 1936, 5, 1937)
- Dziemian, Arthur J**, Ph D Med Div, Army Chemical Center, Md Physiologist, Biophysics Section (1, 1948)
- Eadie, George S**, Ph D Duke Univ School of Medicine, Box 3709, Durham, N C Prof of Physiology and Pharmacology (1, 1929, 3, 1940)
- Eagle, Harry**, M D Natl Insts of Health, Bethesda, Md Chief of Section on Exper Therapeutics, Microbiological Inst (3, 1946, 4, 1936, 6, 1946)
- Eakin, Robert E**, Ph D Univ of Texas, Dept of Chemistry, Austin Assoc Prof of Chemistry (2, 1948)
- Earle, D P, Jr**, M D, Med Sc D New York Univ College of Medicine, 477 First Ave, New York City 16 Assoc Prof of Medicine (1, 1947)
- Earle, Wilton R**, Ph D Natl Cancer Inst, Bethesda, Md Cytologist, Head of Tissue Culture Unit (4, 1940)
- Eaton, Monroe D**, M D Harvard Med School, Boston, Mass Assoc Prof of Bacteriology and Immunology (6, 1937)

- Eckenhoff, James E, M D Hospital of the Univ of Pennsylvania, Philadelphia *Assoc in Clinical Pharmacology and Anesthesiology* (1, 1948)
- Ecker, E E, Ph D Western Reserve Univ School of Medicine, 2085 Adelbert Rd, Cleveland, Ohio *Prof of Immunology* (4, 1925, 6, 1947)
- Eckstein, Gustav, M D Univ of Cincinnati College of Medicine, Cincinnati, Ohio *Assoc Prof of Physiology* (1, 1948)
- Eckstein, Henry C, Ph D Univ of Michigan, 320 W Med Building, Ann Arbor *Assoc Prof of Biological Chemistry* (2, 1925)
- Eckstein, R W, M A, M D Western Reserve Univ, Dept of Medicine, Cleveland, Ohio *Sr Instr, in charge of Cardiovascular Exper Med Research Lab* (1, 1947)
- Eddy, Bernice E, Ph D Natl Insts of Health, Inst of Microbiology, Bethesda 14, Md *Sr Bacteriologist* (6, 1949)
- Eddy, Nathan B, M D Natl Insts of Health, Bethesda, Md *Principal Pharmacologist* (3, 1929)
- Eddy, Walter H, Ph D Box 969 Lake Worth, Fla *Scientific Dir, American Chlorophyll, Inc* (2, 1913, 5, 1933)
- Edelmann, Abraham, Ph D Brookhaven Natl Labs, Upton, L I, N Y *Physiologist* (1, 1948)
- Ederstrom, Helge E, Ph D St Louis Univ School of Medicine, Dept of Physiology, 1402 S Grand Blvd, St Louis 4, Mo *Asst Prof* (1, 1949)
- Edholm, O G, M B Univ of Western Ontario Med School, London, Ontario, Canada *Head, Dept of Physiology* (1, 1948)
- Edsall, Geoffrey, M D Boston Univ School of Medicine, 80 E Concord St, Boston 18, Mass *Prof of Bacteriology* (6, 1943)
- Edsall, John Tileston, M D Harvard Med School, Boston, Mass *Assoc Prof of Biological Chemistry, Tutor in Biochemical Sciences* (2, 1931)
- Edwards, Dayton J, Ph D Cornell Univ Med College, 1300 York Ave, New York City *Assoc Prof of Physiology, Asst Dean* (1, 1921)
- Edwards, Jesse E, M D Mayo Clinic, Rochester 4, Minn *Asst Prof of Pathologic Anatomy, Mayo Foundation* (4, 1941)
- Edwards, J Graham, Ph D 24 High St, Buffalo, N Y *Assoc Prof of Anatomy, Univ of Buffalo* (1, 1932)
- Eggerth, Arnold H, Ph D Hoagland Lab, 335 Henry St, Brooklyn, N Y *Assoc Prof of Bacteriology, Long Island College of Medicine* (4, 1925)
- Ehrenstein, Maximilian R, Ph D Univ of Pennsylvania Hospital, 806 Maloney Clinic, 36th and Spruce Sts, Philadelphia 4 *Assoc Prof of Physiological Chemistry assigned to Medicine, Univ of Pennsylvania School of Medicine* (2, 1942)
- Ehrlich, William E, M D Univ of Pennsylvania, Philadelphia *Prof of Pathology, Grad School of Medicine, Chief, Div of Pathology, Philadelphia General Hospital* (4, 1945)
- Eichelberger, Lillian, Ph D Univ of Chicago, Dept of Surgery, Chicago, Ill *Assoc Prof of Biochemistry* (2, 1937)
- Eichna, Ludwig W, M D New York Univ College of Medicine, Dept of Medicine, 477 First Ave, New York City 16 *Assoc Prof of Medicine, Visiting Physician, Bellevue Hospital* (1, 1949)
- Eiler, John J, Ph D Univ of California Med Center, San Francisco 22 *Assoc Prof of Biochemistry and Pharmacology, Univ of California College of Pharmacy* (2, 1948)
- Eisenman, Anna J, Ph D U S Public Health Service Hospital, Lexington, Ky *Biological Chemist* (2, 1930)
- Elberg, Sanford S, Ph D Univ of California, Berkeley *Assoc Prof of Bacteriology* (6, 1948)
- Elderfield, Robert C, Ph D Columbia Univ, New York City *Prof of Chemistry* (2, 1934)
- Elftman, Herbert, Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City *Assoc Prof in Anatomy*, (1, 1940)
- Eliot, Martha M, M D World Health Organization, Palais des Nations, Geneva, Switzerland. *Asst Dir General* (5, 1933)
- Elkinton, J Russell, M D Univ of Pennsylvania Hospital, Dept of Medicine Philadelphia (1, 1947)
- Elliott, Henry W, Ph D Univ of California Med School, San Francisco *Instr in Pharmacology and Lecturer in Dental Pharmacology and Toxicology* (3, 1948)
- Elliott, K Allan C, Ph D Montreal Neurological Inst, 3801 Univ St, Montreal, Que, Canada *Asst Prof of Exper Neurology and Biochemistry* (2, 1937)
- Ellis, C H, Ph D Labs of Gordon A Alles, 770 S Arroyo Parkway, Pasadena 5, Calif *Research Assoc in Physiology* (1, 1947)
- Ellis, Fred W, Ph D Univ of North Carolina, Chapel Hill *Asst Prof of Pharmacology* (3, 1945)
- Ellis, Lillian N, Ph D Adelphi College, Garden City, N Y *Instr in Chemistry* (5, 1940)
- Ellis, Max Mapes, Ph D Univ of Missouri Med School, Columbia *Prof of Physiology and Pharmacology* (1, 1923)
- Ellis, N R, M S U S Dept of Agriculture, Bureau of Animal Industry, Beltsville, Md *1st Chief, Animal Husbandry Div* (2, 1928, 5, 1933)

- Ellis, Sidney, Ph D Temple Univ Med School, Dept of Pharmacology Philadelphia, Pa (3, 1947)
- Elrod, Ralph P, Ph D Univ of South Dakota Med School, Vermillion *Chairman of Dept of Microbiology* (6, 1947)
- Elser, William J, M D Kent, Conn (6, 1920)
- Elvehjem, Conrad Arnold, Ph D Univ of Wisconsin, Biochemistry Bldg, Madison *Chairman, Dept of Biochemistry, Dean of Grad School* (2, 1931, 5, 1933)
- Embree, Norris Dean, Ph D Distillation Products, Inc, 755 Ridge Rd W, Rochester 13, N Y *Dir of Research* (2, 1946)
- Emerson, George A, Ph D Univ of Texas, Med Branch, Galveston *Prof of Pharmacology* (3, 1935)
- Emerson, Gladys A, Ph D Merck Inst of Therapeutic Research, Rahway, N J *Nutritionist* (5, 1942)
- Emerson, Oliver H, Ph D U S Dept of Agriculture, Western Regional Research Lab, Albany 6, Calif *Assoc Chemist* (2, 1938)
- Emery, Frederick E, D V M, Ph D Univ of Arkansas School of Medicine, Little Rock *Prof of Physiology and Pharmacology* (1, 1930)
- Emmart, Emily W, Ph D Natl Insts of Health, Bethesda 14, Md (3, 1947)
- Emmett, Arthur D, Ph D Star Route 1, Lewiston, Mich (2, 1908, 5, 1933)
- Enders, John F, Ph D Harvard Univ Med School, Dept of Bacteriology, Boston, Mass *Assoc Prof of Bacteriology and Immunology, Chief, Research Div of Infectious Diseases, Children's Hospital* (6, 1936)
- Endicott, Kenneth M, M D USPHS, Natl Insts of Health, Bethesda 14, Md *Chief of Section on Metabolic and Degenerative Disease* (4, 1947)
- Engel, Frank L, M D Duke Univ School of Medicine, Durham, N C *Asst Prof of Medicine* (1, 1947)
- Engel, Lewis L, Ph D, Massachusetts General Hospital, Huntington Labs, Boston *Research Assoc in Biological Chemistry, Harvard Med School, Tutor in Biological Sciences, Harvard Univ* (2, 1949)
- Engel, Ruben W, Ph D Alabama Polytechnic Inst, Lab of Animal Nutrition, Auburn *Animal Nutritionist* (5, 1948)
- Engle, Earl Theron, Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City *Prof of Anatomy* (1, 1930)
- English, James, Jr, Ph D Yale Univ, Sterling Chemistry Lab, New Haven, Conn *Asst Prof of Chemistry* (2, 1946)
- Enright, John B, Ph D State of California Dept of Public Health, Berkeley *Supervising Bacteriologist* (6, 1948)
- Epstein, Albert A, M D 1111 Madison Ave, New York City *Physician, Beth Israel Hospital and Hospital for Joint Diseases* (2, 1912)
- Ercoli, N, M D, Ph D Warner Inst for Therapeutic Research, New York City 11 *Dir of Pharmacological Research* (3, 1947)
- Erickson, Cyrus C, M D Duke Univ School of Medicine, Durham, N C *Assoc Prof of Pathology* (4, 1941)
- Erickson, John Otto, Ph D Veterans Admin Center, Radioisotope Lab, Wilshire and Sawtelle Blvds, Los Angeles 25, Calif (6, 1946)
- Eschenbrenner, Allen B, M D Natl Insts of Health, Bethesda 14, Md (4, 1946)
- Espe, Dwight L, Ph D State College Station, Dept of Dairy Husbandry, Fargo, N D (1, 1940)
- Essex, Hiram E, Ph D Mayo Foundation, Inst of Exper Medicine, Rochester, Minn *Prof of Physiology* (1, 1932, 3, 1940)
- Ettlinger, C H, M D, C M Queen's Univ, Kingston, Ontario, Canada *Prof of Physiology, Asst Dir, Div of Med Research, Natl Research Council, Ottawa* (1, 1943)
- Evans, Earl Alison, Jr, Ph D Univ of Chicago, Dept of Biochemistry, Chicago, Ill *Prof and Chairman of Dept* (2, 1939)
- Evans, Everett Idris, M D, Ph D Med College of Virginia, Richmond *Prof of Surgery, Dir, Lab of Surgical Research* (1, 1935)
- Evans, Gerald Taylor, M D, Ph D Univ of Minnesota Hospitals, Minneapolis *Dir of Lab Service, Assoc Prof of Medicine, Univ of Minnesota* (1, 1942)
- Evans, Herbert M, M D Univ of California, Berkeley *Prof of Anatomy and Dir of Inst of Exper Biology* (1, 1919)
- Evans, Titus C, Ph D State Univ of Iowa, College of Medicine, Iowa City *Research Prof, Head of Radiation Research Lab* (1, 1949)
- Eveleth, D F, Ph D, D V M North Dakota Agricultural College, Fargo *Prof of Veterinary Science, North Dakota Agricultural Exper Station* (2, 1939)
- Everett, Mark R, Ph D Univ of Oklahoma School of Medicine, 800 N E 13th St, Oklahoma City 4 *Dean, School of Medicine, Supt of Univ Hospitals* (2, 1929)
- Everson, Gladys, Ph D Iowa State College, Ames *Assoc Prof of Nutrition* (5, 1948)
- Ewing, P L, Ph D Univ of Texas School of Medicine, Galveston *Assoc Prof of Pharmacology* (3, 1938)
- Eyster, John A English, M D Univ of Wisconsin, Madison *Prof of Physiology* (1, 1906, 3R, 1908)
- Fahr, George, M D Univ of Minnesota, 102 Millard Hall, Minneapolis *Prof of Clinical Medicine* (1, 1913, 3, 1940)

- Failey, Crawford F, Ph D 416 S 6th St, Terre Haute, Ind *Prof of Biochemistry, Univ of Chicago* (2, 1933)
- Fairhall, Lawrence T, Ph D USPHS, Washington, D C *Principal Industrial Toxicologist* (2, 1924)
- Falk, Carolyn R, B A 40 E 66th St, New York City *Bacteriologist, Bureau of Labs, Dept of Health* (6, 1943)
- Falk, K George, Ph D 40 E 66th St, New York City *Dir, Lab of Industrial Hygiene* (2, 1913)
- Farah, Alfred E, M D Univ of Washington School of Medicine, Seattle *Asst Prof of Pharmacology* (3, 1948)
- Farber, Sidney, M D Harvard Med School, 25 Shattuck St, Boston, Mass *Asst Prof of Pathology* (4, 1934)
- Farmer, Chester J, A M Northwestern Univ Med School, 303 E Chicago Ave, Chicago, Ill *Prof of Chemistry* (2, 1935)
- Farr, Lee E, M D Brookhaven Natl Lab, Upton, L I, N Y *Dir, Dept of Med Sciences, Physician-in-Chief, Brookhaven Natl Lab Hospital* (4, 1941)
- Farrar, George E, Jr, M D Wyeth Inc, 1600 Arch St, Philadelphia 3, Pa *Med Dir* (3, 1947)
- Farrell, James L, Ph D, M D 636 Church St, Evanston, Ill (1, 1938)
- Fassett, David W, M D Eastman Kodak Co, Lab of Industrial Medicine, Kodak Park Works, Rochester, N Y (3, 1942)
- Fay, Marion, Ph D Woman's Med College of Pennsylvania, Philadelphia 29 *Dean, Prof of Physiological Chemistry* (2, 1937)
- Featherstone, Robert M, Ph D State Univ of Iowa, College of Medicine, Iowa City *Asst Prof of Pharmacology* (3, 1947)
- Feigen, George A, Ph D Stanford Univ, Dept of Physiology, Stanford, Calif *Instructor* (1, 1948)
- Feldman, Harry A, M D 704 Crawford Ave, Syracuse 10, N Y (6, 1943)
- Feldman, William H, D V M, M S Mayo Foundation, Rochester, Minn *Prof in the Div of Exper Surgery and Pathology* (4, 1934)
- Fell, Norbert, Ph D Camp Detrick, Frederick, Md *Chief, Pilot Plant Div* (6, 1944)
- Feller, A E, M D Western Reserve School of Medicine, Cleveland 6, Ohio *Assoc Prof of Preventive Medicine* (6, 1943)
- Fellows, Edwin J, Ph D Temple Univ School of Medicine, Philadelphia, Pa *Asst Prof of Pharmacology* (3, 1939)
- Felsenfeld, Oscar, M D, D T M & H Hektoen Research Inst, 629 South Wood St, Chicago 12, Ill *Dir of Bacteriology* (6, 1949)
- Felton, Lloyd D, M D, D Sc USPHS, Natl Insts of Health, Bethesda, Md *Med Dir* (6, 1926)
- Fenn, Wallace Osgood, Ph D Univ of Rochester School of Medicine and Dentistry, 260 Crittenden Blvd, Rochester, N Y *Prof of Physiology* (1, 1924)
- Fenning, Con, M D Univ of Utah School of Medicine, Salt Lake City *Prof of Pharmacology and Physiology* (1, 1942)
- Fenton, P F, Ph D Brown Univ, Providence, R I *Assoc Prof of Biology* (1, 1947, 5, 1949)
- Ferguson, Frederick P, Ph D Univ of Maryland School of Medicine, Dept of Physiology, Baltimore 1 (1, 1949)
- Ferguson, James Kenneth Wallace, M A, M D 76 Kilbarry Rd, Toronto, Ont, Canada *Prof of Pharmacology, Univ of Toronto, Wing Comdr, R C A F* (1, 1933, 3, 1941)
- Ferguson, John, Ph D Creighton Univ School of Medicine, Omaha 2, Neb *Asst Prof of Physiology* (1, 1949)
- Ferguson, John Howard, M A, M D Univ of North Carolina School of Medicine, Dept of Physiology, Chapel Hill *Prof of Physiology and Acting Prof of Pharmacology* (1, 1933)
- Ferguson, L Kraeer, M D 133 S 36th St, Philadelphia 4, Pa *Prof of Surgery, Grad School, Univ of Pennsylvania, Surgeon, Doctors' Hosp and Woman's Med College, Philadelphia General Hosp* (4, 1935)
- Ferguson, Ralph L, M D Univ of South Dakota Med School, Dept of Pathology, Vermillion *Prof of Pathology* (4, 1949)
- Ferry, John Douglass, Ph D Univ of Wisconsin, Dept of Chemistry, Madison *Prof of Chemistry* (2, 1941)
- Ferry, Ronald M, M D 966 Memorial Drive, Cambridge, Mass *Assoc Prof of Biochemistry, Harvard Univ* (2, 1924)
- Fetcher, Edwin S, Ph D Steamboat Springs, Colo (1, 1944)
- Fetter, Dorothy, Ph D Brooklyn College, Dept of Hygiene, Brooklyn, N Y *Instr in Physiology* (1, 1944)
- Fevold, Harry L, Ph D Quartermaster Food and Container Inst, 1849 W Pershing Rd, Chicago 9, Ill *Chief, Food Research Div* (2, 1942)
- Field, John, II, Ph D Navy Dept Office of Naval Research, Med Sciences Div, Washington, D C *Head of Ecology Branch* (1, 1930)
- Fincke, Margaret L, Ph D Oregon State College, Corvallis *Assoc Prof of Foods and Nutrition, School of Home Economics* (5, 1940)
- Findley, Thomas, Jr, M D Ochsner Clinic, 3503 Prytania, New Orleans, La *Head of Dept of Internal Medicine, Asst Prof of Clinical Medicine, Tulane Univ School of Medicine* (1, 1938)

- Finerty, John C**, Ph D Univ of Texas Med Branch, Dept of Anatomy, Galveston Assoc Prof of Anatomy (1, 1947)
- Finland, Maxwell, M D** Boston City Hospital, Boston, Mass Asst Prof of Medicine, Harvard Med School (6, 1941)
- Finnegan, J K**, Ph D Med College of Virginia, Richmond 19 Asst Prof of Pharmacology (3, 1947)
- Firor, Warfield Monroe, M D** Johns Hopkins Hospital, Baltimore, Md Assoc Prof of Surgery, Johns Hopkins Univ (1, 1932)
- Fischel, Edward E**, M D, D Med Sc 23 Haven Ave, New York City 32 Fellow in Medicine, Columbia Univ (6, 1948)
- Fischer, Ernst, M D** Med College of Virginia, Richmond Prof of Physiology (1, 1936)
- Fischer, Hermann O L**, Ph D Univ of California, Virus Lab, Forestry Bldg, Berkeley 4 Lecturer, Dept of Biochemistry (2, 1940)
- Fischer, Martin H**, M D Univ of Cincinnati College of Medicine, Eden Ave, Cincinnati 19, Ohio Prof of Physiology (1, 1901, 2, 1919)
- Fishberg, Ella H**, M A, M D Beth Israel Hospital, Stuyvesant Park E, New York City Biochemist (2, 1931)
- Fisher, Alpert Madden, Ph D** Univ of Toronto, Connaught Med Research Labs, Toronto 5, Ont, Canada Research and Admin Assoc (2, 1944)
- Fisher, Kenneth C**, Ph D Univ of Toronto, Toronto, Ont, Canada Asst Prof of Physiological Zoology (1, 1940)
- Fishman, William H**, Ph D Tufts College Med School, 30 Bennet St, Boston 15, Mass Research Prof of Biochemistry (2, 1947)
- Fiske, Cyrus H**, M D Harvard Med School, Boston, Mass Prof of Biological Chemistry (2, 1914)
- Fitzhugh, O Garth, Ph D** Federal Security Agency, Food and Drug Admin, Div of Pharmacology, Washington, D C Pharmacologist (3, 1940)
- Fleischmann, Walter, M D**, Ph D Med Div, Army Chemical Center, Md Chief, Physiology Section, Instr in Pediatrics, Johns Hopkins Univ (1, 1940)
- Fleisher, Moyer S**, M D Jewish Hospital, St Louis, Mo Research Bacteriologist (4, 1924, 6, 1932)
- Flexner, Louis B**, M D Carnegie Labs, Carnegie Inst of Washington, Wolfe and Madison Sts, Baltimore 5, Md Staff member, Dept of Embryology (1, 1933, 2, 1948)
- Flick, John A** Univ of Pennsylvania School of Medicine, Dept of Bacteriology, Philadelphia 4 (6, 1949)
- Flock, Eunice V**, Ph D Mayo Clinic, Rochester, Minn Assoc Prof in Exper Medicine, Mayo Foundation, Univ of Minnesota (2, 1940)
- Florman, Alfred L**, M D Mt Sinai Hospital, New York City Investigator in Virology (6, 1942)
- Flosdorf, Earl W**, Ph D Forest Grove, Pa Dir of Research, Univ of Pennsylvania School of Medicine (6, 1941)
- Floyd, Cleveland, M D**, Sc D 246 Marlborough St, Boston, Mass Chief Examiner, Boston Health Dept (6, 1916)
- Foa, Piero Pio, Ph D** 710 S Wolcott St, Chicago, Ill Assoc Prof of Physiology and Pharmacology, Chicago Med School (1, 1944)
- Folch, Jordi, M D** McLean Hospital, Waverly, Mass Asst Prof of Biological Chemistry, Harvard Med School, Dir of Scientific Research, McLean Hospital (2, 1941)
- Folkers, Karl, Ph D** Merck and Co, Inc, Rahway, N J Dir of Organic and Biochemical Research (2, 1947)
- Follensby, Edna M**, Ph D 80 E Concord St, Boston, Mass Research Asst, Evans Memorial, Special Instr in Biology, Simmons College (6, 1933)
- Follis, Richard H, Jr, M D** Johns Hopkins Univ School of Medicine, Baltimore, Md Assoc Prof of Pathology (4, 1942)
- Fontaine, Thomas Davis, Ph D** U S Dept of Agriculture, Bureau of Agric and Indust Chemistry, Beltsville, Md Biochemist, Head, Div of Biologically Active Compounds (2, 1946)
- Foot, Nathan Chandler, M D** Cornell Univ Med College, New York City Prof Emeritus of Surgical Pathology (4, 1924)
- Forbes, Alexander, A.M**, M D Harvard University, Biological Labs, Divinity Ave, Boston, Mass (1, 1910)
- Forbes, Ernest B**, Ph D State College, Pa Prof Emeritus of Animal Nutrition (1R, 1917, 5, 1935)
- Forbes, John C**, Ph D Med College of Virginia, Richmond Research Prof of Biochemistry (2, 1937)
- Forbes, William H**, Ph D Harvard Univ, Boston, Mass Asst Dir, Fatigue Lab, Asst Prof of Industrial Physiology (1, 1943)
- Forster, Francis M**, M D Jefferson Med College, Philadelphia, Pa Asst Prof of Neurology (1, 1948)
- Fosdick, Leonard S**, Ph D 311 E Chicago Ave, Chicago, Ill Prof of Chemistry, Northwestern Univ (2, 1944)
- Foster, G L**, Ph D Columbia Univ, College of Physicians and Surgeons, 630 W 168th St, New York City Prof of Biological Chemistry (2, 1923)
- Foster, Harry E**, M D Fairmont Hotel, San Francisco, Calif (6, 1913)

- Foster, Jackson W, Ph D Univ of Texas, Dept of Bacteriology, Austin 12 *Prof of Bacteriology* (2, 1946)
- Foster, Robert H K, Ph D, M D St Louis Univ School of Medicine, St Louis, Mo *Prof and Dir of Dept of Pharmacology* (1, 1940, 3, 1944)
- Foster, Ruth A C, Ph D Princeton Univ, Princeton, N J (6, 1943)
- Fothergill, LeRoy D, M D Camp Detrick, Frederick, Md *Asst Technical Dir* (6, 1936)
- Fox, Sidney W, Ph D Iowa State College, Chemistry Dept, Ames *Prof of Chemistry, Prof in charge, Chemistry Section, Iowa Agricultural Exper Station* (2, 1946)
- Fraenkel, Gottfried S, Ph D Univ of Illinois, Urbana *Prof of Entomology* (5, 1949)
- Fraenkel-Conrat, Heinz, M D, Ph D U S Dept of Agriculture, Western Regional Research Lab, Albany 6, Calif *Sr Chemist* (2, 1942)
- Francis, Thomas, Jr, M D Univ of Michigan School of Public Health, Ann Arbor *Henry Sewall Prof of Epidemiology* (4, 1940, 6, 1930)
- Franke, Florent E, M D 9 Sylvester Ave, Webster Groves, Mo *Asst Prof of Physiology, St Louis Univ School of Medicine* (1, 1934)
- Frankel, Edward M, Ph D 214 River Rd, Nyack 9, N Y *Consulting Chemist* (2, 1916)
- Fraps, R M, Ph D Bureau of Animal Husbandry, Beltsville, Md *Sr Physiologist* (1, 1947)
- Fraser, Donald T, M B, D P H Univ of Toronto, Connaught Labs, Toronto 5, Canada *Prof of Hygiene and Preventive Medicine* (6, 1935)
- Frear, Donald E H, Ph D Pennsylvania State College, Dept of Agricultural and Biological Chemistry, State College *Prof of Agricultural and Biological Chemistry* (2, 1946)
- Fredette, Victorian Univ of Montreal, Montreal, Que, Canada *Asst Prof of Bacteriology, Assoc Dir, Inst of Microbiology* (6, 1948)
- Free, Alfred H, Ph D Miles Labs, Inc, Research Lab, Elkhart, Ind *Head of Biochemistry Section* (2, 1946, 5, 1944)
- Freeman, Harry, M D Worcester State Hospital, Worcester, Mass *Internist, Research Service* (1, 1939)
- Freeman, Leslie Willard, Ph D, M D Univ of Indiana, Dept of Surgery, Indianapolis *Asst Prof of Surgery, Dir of Surgical Research* (1, 1944)
- Freeman, Norman E, M D Univ of California Med School, Dept of Surgery, San Francisco 22 (1, 1936)
- Freeman, Smuth, M D, Ph D Northwestern Univ School of Medicine, 303 E Chicago Ave, Chicago, Ill *Prof and Chairman of Dept of Exper Medicine* (1, 1937)
- French, Cyrus E, Ph D Pennsylvania State College, State College *Assoc Prof of Animal Nutrition* (5, 1948)
- French, C Stacy, Ph D Carnegie Institution of Washington, Stanford Univ, Calif *Dir, Div of Plant Biology* (1, 1947, 2, 1946)
- Freund, Jules, M D Public Health Research Inst of the City of New York, New York City *Chief of the Div of Applied Immunology* (6, 1924)
- Frey, Charles N, Ph D Standard Brands Inc, 595 Madison Ave at 57th St, New York City 22 *Dir, Scientific Relations* (5, 1948)
- Fried, Josef, Ph D Squibb Inst for Med Research, New Brunswick, N J *Assoc Member, Div of Organic Chemistry* (2, 1948)
- Friedemann, Theodore E, Ph D Northwestern Univ Med School, 303 E Chicago Ave, Chicago, Ill *Assoc Prof of Physiology* (2, 1925)
- Friedemann, Ulrich, M D Jewish Hospital of Brooklyn, Dept of Bacteriology, Classon and St Marks Ave, Brooklyn, N Y (6, 1938)
- Friedenwald, Jonas S, M A, M D 1212 Eutaw Place, Baltimore 17, Md *Assoc Prof of Ophthalmology, Johns Hopkins Hospital* (1, 1947)
- Friedewald, William F, M D Emory Univ School of Medicine, Atlanta, Ga *Prof of Bacteriology, Assoc Prof of Medicine* (4, 1941)
- Friedgood, Harry B, M D Univ of California, Los Angeles *Assoc Clinical Prof of Medicine, Pres and Chairman, California Inst of Cancer Research* (1, 1936)
- Friedman, Maurice H, Ph D, M D 2040 Belmont Rd, Washington 9, D C (1, 1929)
- Friedman, Meyer, M D Harold Brunn Inst for Cardiovascular Research, Mt Zion Hospital, 2200 Post St, San Francisco, Calif *Director* (1, 1947)
- Friedman, M H F, Ph D Jefferson Med College of Philadelphia, 1025 Walnut St, Philadelphia, Pa *Assoc Prof of Physiology* (1, 1941)
- Friedman, Nathan B, M D Cedars of Lebanon Hospital, 4833 Fountain Ave, Los Angeles, Calif (4, 1942)
- Friedman, Sydney M, M D, Ph D McGill Univ, Dept of Anatomy, Montreal 2, Que, Canada *Asst Prof of Anatomy* (1, 1947)
- Friedman, Townsend B Children's Memorial Hospital, Chicago, Ill *Attending Allergist* (6, 1948)
- Frost, Douglas Van Anden, Ph D Abbott Labs, N Chicago, Ill *Head of Nutritional Research* (2, 1946, 5, 1947)
- Fruton, J S, Ph D Yale School of Medicine, 333 Cedar St, New Haven, Conn *Assoc Prof of Physiological Chemistry* (2, 1938)

- Fugo, Nicholas W**, Ph D Univ of Chicago, Dept of Obstetrics and Gynecology, Chicago, Ill (3, 1944)
- Fuhrman, Frederick A**, Ph D Stanford Univ, Dept of Physiology, Stanford Univ, Calif *Asst Prof of Physiology* (1, 1946)
- Fulton, John Farquhar**, Ph D, M D Yale Univ School of Medicine, New Haven, Conn *Sterling Prof of Physiology* (1, 1925)
- Funk, Casimir, D Sc**, Ph D 186 Riverside Drive, New York City 24 (2, 1921)
- Furchgott, Robert F**, Ph D Washington Univ School of Medicine, Euclid Ave and Kingshighway, St Louis 10, Mo *Asst Prof of Pharmacology* (2, 1948)
- Furth, Jacob**, M D Oak Ridge Natl Lab, Oak Ridge, Tenn *Chief of Pathology Section, Div of Biology* (4, 1932, 6, 1930)
- Gaebler, Oliver H**, Ph D, M D Henry Ford Hospital, Detroit, Mich *Head, Dept of Biochemistry, Edsel B Ford Inst for Med Research* (2, 1927)
- Gaffron, Hans**, Ph D Univ of Chicago, Dept of Chemistry, 5747 Ellis Ave, Chicago 37, Ill *Assoc Prof of Biochemistry, Member, Inst of Radio Biology and Biophysics* (2, 1941)
- Gagge, Adolf Pharo**, Ph D Aeromedical Research Lab, Wright Field, Dayton, Ohio *Lt Col, Chief, Biophysics Branch, Air Corps, U S Army* (1, 1939)
- Galambos, Robert**, Ph D, M D Psycho-Acoustic Lab, Cambridge, Mass *Research Fellow, Harvard Univ* (1, 1942)
- Gall, Edward A**, M D Cincinnati General Hospital, Cincinnati, Ohio *Mary M Emery Prof of Pathology, Univ of Cincinnati College of Medicine* (4, 1941)
- Gallagher, Thomas F**, Ph D Sloan-Kettering Inst, 444 E 68th St, New York City 21 *Member* (2, 1932)
- Gallup, Willis D**, Ph D Oklahoma Agricultural and Mechanical College, Stillwater *Chemist and Prof of Agricultural Chemistry* (2, 1932)
- Gamble, James L**, M D, S M 33 Edgehill Rd, Brookline, Mass *Prof of Pediatrics, Harvard Med School* (2, 1922, 5, 1933)
- Gantt, W Horsley**, M D Johns Hopkins Hospital, Phipps Psychiatric Clinic, Baltimore, Md *Assoc in Psychiatry* (1, 1935)
- Garbat, Abraham L**, M D 103 E 78th St, New York City *Dir, Med Service, Lenox Hill Hospital, Clinical Prof of Medicine, New York Univ Med School* (6, 1913)
- Gardner, Ernest**, M D Wayne Univ College of Medicine, Dept of Anatomy, 1512 St Antoine St, Detroit 26, Mich *Asst Prof of Anatomy* (1, 1949)
- Garner, Raymond L**, Ph D Univ of Michigan Med School, 218 W Med Bldg, Ann Arbor *Asst Prof of Biological Chemistry* (2, 1947)
- Garrey, Walter Eugene**, Ph D, M D Vanderbilt Univ School of Medicine, Nashville, Tenn *Prof Emeritus of Physiology* (1R, 1910, 2, 1906)
- Gasser, Herbert S**, A M, M D Rockefeller Inst for Med Research, 66th St and York Ave, New York City *Dir of Labs* (1, 1915, 3, 1924)
- Gassner, Frank X**, M S, D V M Colorado A and M College, Fort Collins *Assoc Prof of Physiology, Colorado State College, Assoc Pathologist, Colorado State Exper Station* (1, 1947)
- Gates, Olive**, M D Harvard Med School, 25 Shattuck St, Boston, Mass *Assoc Pathologist* (4, 1940)
- Gaunt, Robert**, Ph D Syracuse Univ, Syracuse, N Y *Prof and Chairman of Dept of Zoology* (1, 1939)
- Gay, Leslie N**, M D 1114 St Paul St, Baltimore, Md *Dir of Allergy Clinic, Johns Hopkins Hospital, Assoc Prof of Medicine, Johns Hopkins Univ* (6, 1927)
- Geiling, E M K**, M D, Ph D Univ of Chicago, Chicago 37, Ill *Frank P Hixon Distinguished Service Prof of Pharmacology and Chairman of Dept* (1, 1933, 2, 1927, 3, 1925)
- Gelfan, Samuel**, Ph D Yale Univ School of Medicine, 333 Cedar St, New Haven 11, Conn *Asst Prof of Physiology* (1, 1930)
- Gellhorn, Alfred**, M D Columbia Univ College of Physicians and Surgeons, Dept of Pharmacology, 630 W 168th St, New York City 32 *Assoc Prof of Pharmacology* (3, 1946)
- Gellhorn, Ernst**, M D, Ph D Univ of Minnesota, Room 116, Med Sciences, Minneapolis *Prof of Neurophysiology* (1, 1930)
- Gemmell, Chalmers L**, M D Univ of Virginia Med School, Charlottesville *Prof of Pharmacology* (1, 1928, 2, 1935, 3, 1946)
- Gerard, R W**, Ph D, M D Univ of Chicago, Chicago, Ill *Prof of Physiology* (1, 1927)
- Gersh, Isadore**, Ph D Univ of Chicago, Dept of Anatomy, Chicago 37, Ill *Assoc Prof of Anatomy* (4, 1947)
- Gerstenberger, Henry John**, M D Western Reserve Univ School of Medicine, Cleveland, Ohio *Prof Emeritus of Pediatrics, Dir of Pediatrics, Babies and Children's Hospital* (5, 1938)
- Gesell, Robert**, M D Univ of Michigan, Ann Arbor *Prof of Physiology* (1, 1913)
- Gettler, Alexander O**, Ph D New York Univ, 29 Washington Square, New York City *Prof of Chemistry and Toxicology, Toxicologist to Chief Med Examiner's Office* (2, 1916)
- Gey, George Otto**, M D Johns Hopkins Univ, Baltimore, Md *Instr in Surgery* (1, 1940)
- Gibbard, J**, M Sc Dept of Natl Health and Welfare, Ottawa, Ont, Canada *Chief, Lab of Hygiene* (6, 1946)
- Gibbs, Frederick Andrews**, M D 720 N Michigan Ave, Suite 610 Chicago Ill (1 1935)

- Gibbs, Owen Stanley, M D P O Box 166, White haven, Tenn *Dir*, *Gibbs Med Research Lab* (1, 1935, 3, 1930)
- Gibson, Robert Banks, Ph D Univ Hospital, Iowa City, Iowa *Assoc Prof of Biochemistry, State Univ of Iowa* (1, 1907, 2, 1906)
- Gies, William John, Ph D Columbia Univ, 632 W 168th St, New York City *Prof of Biological Chemistry* (1R, 1898, 2, 1906, 3R, 1909)
- Gilbert, Ruth, A M, M D R F D 2, Altamont, N Y *Asst Dir*, *Diagnostic Labs*, New York *State Dept of Health*, Albany (6, 1920)
- Gilman, Alfred, Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Prof of Pharmacology* (1, 1935, 3, 1934)
- Gilson, Arthur S, Jr, Ph D Washington Univ Med School, St Louis, Mo *Assoc Prof of Physiology* (1, 1927)
- Givens, Maurice H, Ph D Box 5116, Biltmore, N C (1, 1917, 2, 1915)
- Gjessing, Erland C, Ph D Univ of Virginia, Box 1062, Univ Station, Charlottesville *Asst Prof of Biochemistry* (2, 1948)
- Glass, Howard G, Ph D 514 Wesley Ave, Oak Park, Ill (3, 1947)
- Glazko, Anthony J, Ph D Parke, Davis and Co, Research Labs, Detroit 32, Mich *Research Biochemist* (1, 1942)
- Glick, David, Ph D Univ of Minnesota, 225 Med Sciences Bldg, Minneapolis 14 *Assoc Prof of Physiological Chemistry* (2, 1936)
- Glickman, Nathaniel, M S Univ of Illinois College of Medicine, Dept of Medicine, 1853 W Polk St, Chicago 12 *Asst Prof of Medicine and Research Physiologist* (1, 1947)
- Goebel, Walther F, Ph D Rockefeller Inst for Med Research, 66th St and York Ave, New York City *Member* (2, 1929, 6, 1937)
- Goerner, Alfred, Pharm D, M D 366 Sterling Place, Brooklyn, N Y *Asst Clinical Prof of Medicine*, Long Island College of Medicine (2, 1939)
- Goettsch, Marianne, Ph D School of Tropical Medicine of Columbia Univ, San Juan, Puerto Rico *Asst Prof of Chemistry* (2, 1933, 5, 1941)
- Goetzl, Franz R, Ph D, M D Permanente Foundation, Dept of Med Research, Oakland 11, Calif *Director* (1, 1947)
- Gold, Harry, M.D Cornell Univ Med College, New York City *Prof of Clinical Pharmacology, Attending Physician-in-Charge, Cardiovascular Research Unit, Beth Israel Hospital* (3, 1927)
- Goldblatt, Harry, M D Cedars of Lebanon Hospital, Los Angeles, Calif *Dir*, *Inst for Med Research* (1, 1945, 4, 1927)
- Golden, Alfred, M D Veterans Admin Hosp, Buffalo, N Y *Chief of Lab Service*, Univ of Buffalo, *Dept of Physiology* (4, 1947)
- Goldfarb, Walter, M D 25 E 86th St, New York City (1, 1938)
- Goldforb, A J, Ph D College of the City of New York, New York City *Prof of Biology* (1, 1930)
- Goldie, Horace, M D, D T M 7910 Lynnbrook Drive, Bethesda, Md (6, 1943)
- Goldring, William, M D New York Univ College of Medicine, 477 First Ave, New York City *Assoc Prof of Medicine* (1, 1939)
- Goldschmidt, Samuel, Ph D Univ of Pennsylvania Med School, Philadelphia *Prof of Physiology* (1, 1919, 2, 1915)
- Goldsmith, Grace A, M D Tulane Univ of Louisiana, New Orleans *Asst Prof of Medicine* (5, 1943)
- Goldstein, Avram, M D Harvard Med School, Boston, Mass *Instr in Pharmacology* (3, 1948)
- Golub, Orville Joseph, Ph D Bio-Service Labs, Inc, 10717 Venice Blvd, Los Angeles 24, Calif *Associate* (6, 1944)
- Gomori, George, M D, Ph D Univ of Chicago, Chicago, Ill *Prof of Medicine* (4, 1948)
- Goodale, Walter T, M D 79 Webster Rd, Weston 93, Mass *Research Fellow*, *Harvard Med School*, *Asst in Medicine*, *Peter Bent Brigham Hospital* (1, 1949)
- Goodman, Louis Sanford, M S, M D Univ of Utah School of Medicine, Salt Lake City *Prof of Pharmacology and Chairman of Dept of Pharmacology* (1, 1946, 3, 1937)
- Goodner, Kenneth, Ph D Jefferson Med College, Philadelphia, Pennsylvania *Prof of Bacteriology* (6, 1932)
- Goodpasture, Ernest William, M D Vanderbilt Univ Med School, Nashville, Tenn *Prof of Pathology and Dean* (4, 1923)
- Gordon, Albert S, Ph D New York Univ, Washington Square College of Arts and Sciences, New York City *Assoc Prof of Biology* (1, 1942)
- Gordon, Francis B, M D Camp Detrick, Biology Dept, Frederick, Md *Chief of MV Div* (4, 1947)
- Gordon, Harry H, M D 4200 E 9th Ave, Denver, Colo *Prof of Pediatrics*, *Univ of Colorado Med School*, *Pediatrician in Chief*, *Colorado Gen Hospital* (5, 1940)
- Gordon, Irving, M D New York State Dept of Health, Div of Labs and Research, New Scotland Ave, Albany 1 *Assoc Med Bacteriologist*, *Assoc Prof of Medicine and Bacteriology*, *Albany Med College* (6, 1943)
- Gordon, William G, Ph D U S Dept of Agriculture, Eastern Regional Research Lab, Philadelphia 18, Pa *Sr Chemist* (2, 1939)
- Gortner, Ross Aiken, Jr, Ph D Wesleyan Univ, Shanklin Lab, Middletown, Conn *Assoc Prof of Biochemistry* (5, 1947)
- Gortner, Willis A, Ph D Pineapple Research Inst of Hawaii, Honolulu, T H *Head of Dept of Chemistry* (2, 1947)

- Goss, Harold, Ph D Univ of California College of Agriculture, Davis *Prof of Animal Husbandry* (2, 1936, 5, 1933)
- Goth, Andres, M D Southwestern Med College, 2211 Oak Lawn Ave, Dallas 4, Tex *Assoc Prof of Pharmacology* (3, 1947)
- Gottschall, Russell Y, Ph D Michigan Dept of Health, Bureau of Labs, Lansing *Bacteriologist* (6, 1939)
- Goudsmit, Arnoldus, Jr, M D, Ph D 4141 Windsor Rd, Youngstown 7, Ohio (1, 1940)
- Gould, R Gordon, Ph D Presbyterian Hospital, 1753 W Congress St, Chicago 12, Ill *Assoc Attending Biochemist, Assoc Prof of Biological Chemistry, Univ of Illinois College of Medicine* (2, 1949)
- Govier, William M, M D Upjohn Co, Research Div, Kalamazoo 99, Mich (3, 1944)
- Grabfield, G Philip, M D 27 Forest St, Milton, Mass *Assoc in Medicine and Pharmacology, Harvard Med School, Col M C, U S A* (3, 1923)
- Grady, Hugh G, M D Armed Forces Inst of Pathology, Washington, D C *Scientific Dir, Am Registry of Pathology* (4, 1940)
- Graef, Irving, M D New York Univ College of Medicine, New York City *Asst Prof of Clin Medicine* (4, 1941)
- Graham, Claire E, Ph D Wilson Labs, 4221 S Western Ave, Chicago, Ill *Dir of Research* (2, 1948)
- Graham, Clarence H, Ph D Columbia Univ, New York City 27 *Prof of Psychology* (1, 1933)
- Graham, Helen Tredway, Ph D Euclid Ave and Kingshighway, St Louis, Mo *Assoc Prof of Pharmacology, Washington Univ School of Medicine* (1, 1933, 3, 1931)
- Granick, S, Ph D Rockefeller Inst for Med Research, York Ave at 66th St, New York City 21 *Associate* (2, 1949)
- Grant, E Rhoda, Ph D Univ of Illinois Med College, Clinical Science Dept, 1853 West Polk St, Chicago 12, Ill *Researcher in Clin Science* (1, 1949)
- Grant, R Lorimer, Ph D Federal Security Agency, Food and Drug Admin, Div of Pharmacology, Washington 25, D C *Pharmacologist* (2, 1938)
- Grant, Wilson Clark, Ph D 65 Beucler Place, Bergenfield, N J *Asst Prof of Physiology, Columbia Univ College of Physicians and Surgeons* (1, 1949)
- Grau, Charles R, Ph D Univ of California, Div of Poultry Husbandry, Berkeley 4 *Asst Prof of Poultry Husbandry and Asst Poultry Husbandman in Exper Station* (5, 1949)
- Graubard, Mark, Ph D Univ of Minnesota, Dept of Physiology, Minneapolis (1, 1940)
- Grauer, Robert C, M.D Allegheny General Hospital, Pittsburgh, Pa *Dir of Research, and Head of Dept of Endocrinology and Metabolism, William H Singer Memorial Research Lab, Prof of Medicine, School of Medicine, Univ of Pittsburgh* (4, 1941)
- Gray, John S, Ph D, M D Northwestern Univ Med School, 303 E Chicago Ave, Chicago 11, Ill *Prof and Chairman of Dept of Physiology* (1, 1937)
- Gray, M Geneva, Ph D Labs of Arthur D Little Inc, Cambridge, Mass *Dir of Pharmacological Research* (3, 1946)
- Gray, Samuel H, M D Jewish Hospital of St Louis, Kingshighway and Forest Park Blvd, St Louis, Mo *Dir of Labs, Assoc Prof of Pathology, Washington Univ* (4, 1939)
- Gray, Stephen W, Ph D Emory Univ School of Medicine, Emory Univ, Ga *Asst Prof of Anatomy* (1, 1948)
- Graybiel, Ashton, M D U S Naval School of Aviation Medicine and Research, Naval Air Station, Pensacola, Fla *Coordinator of Research* (1, 1948)
- Greaves, J D, Ph D U S Dept of Agriculture, Western Regional Research Lab, 800 Buchanan St, Albany 6, Calif *Biochemist* (2, 1938)
- Greaves, Joseph E, Ph D Utah State Agricultural College, Dept of Bacteriology and Biochemistry, Logan (2, 1940)
- Greeley, Paul O, Ph D, M D Univ of Southern California Med School, Dept of Aviation Medicine, Univ Park, Los Angeles (1, 1940)
- Green, Arda Alden, M D Cleveland Clinic, Research Div, Euclid and E 93rd St, Cleveland 6, Ohio (2, 1932)
- Green, Daniel M, M D G D Searle Co, Chicago 80, Ill *Dir of Biological Research* (1, 1948, 3, 1942)
- Green, David E, Ph D Univ of Wisconsin, Enzyme Inst, P O Box 2066 Madison 5 *Prof of Enzyme Chemistry* (2, 1941)
- Green, Harold David, M D Wake Forest College, Bowman Gray School of Medicine, Winston-Salem 7, N C *Prof of Physiology and Pharmacology* (1, 1936, 3, 1945)
- Green, Robert Holt Yale Univ School of Medicine, 333 Cedar St, New Haven, Conn (6, 1949)
- Greenberg, David Morris, Ph D Univ of California, Berkeley 4 *Prof and Chairman, Div of Biochemistry* (2, 1927, 5, 1946)
- Greenberg, Louis D, Ph D Univ of California Med Center, 3rd and Parnassus Aves, San Francisco 22 *Asst Prof of Pathology, Univ of California Med School* (2, 1946)
- Greene, Carl Hartley, Ph D, M D 401 Clinton Ave, Brooklyn 5, N Y *Assoc Clin Prof of Medicine, New York Univ Post-Grad Med School* (1, 1921, 2, 1922, 4, 1924)

- Greene, Harry S N, M D, C M Yale Univ School of Medicine, Dept of Pathology, New Haven, Conn *Prof of Pathology* (4, 1937)
- Greene, James Alexander, M D Baylor Univ College of Medicine, Buffalo Drive, Houston, Tex *Prof and Chairman of Dept of Internal Medicine and Dean of Clin Faculty* (1, 1939)
- Greene, Ronald R, M D Northwestern Univ Med School, 303 E Chicago Ave, Chicago, Ill *Instr in Physiology, Instr in Obstetrics and Gynecology* (1, 1941)
- Greengard, Harry, Ph D, M D Northwestern Univ Med School, 303 E Chicago Ave, Chicago, Ill *Asst Prof of Physiology* (1, 1939)
- Greenstein, Jesse P, Ph D Natl Cancer Inst, Bethesda, Md *Chief Biochemist* (2, 1935)
- Greenwald, Isidor, Ph D New York Univ College of Medicine, 477 First Ave, New York City *Assoc Prof of Chemistry* (2, 1912, 5, 1933)
- Greep, Roy O, Ph D Harvard School of Dental Medicine, 25 Shattuck St, Boston 15, Mass *Assoc Prof of Dental Science* (1, 1940)
- Greer, C M, M S Vanderbilt Univ School of Medicine, Nashville, Tenn *Research Assoc in Pharmacology* (3, 1938)
- Gregersen Magnus I, Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Prof of Physiology* (1, 1933)
- Gregg, Donald Eaton, Ph D, M D Field Research Lab, Med Dept, Fort Knox, Ky *Chief Research Physician* (1, 1933)
- Gregory, John E, Hahnemann Med College, Philadelphia, Pa *Prof of Pathology* (6, 1948)
- Gregory, Raymond L, Ph D, M D Univ of Texas School of Medicine, 1419 24th St, Galveston *Prof of Medicine* (1, 1945)
- Greig, Margaret E, Ph D Vanderbilt Univ School of Medicine, Nashville 4, Tenn *Assoc Prof in Pharmacology* (3, 1946)
- Greisheimer, Esther M, Ph D M D Temple Univ Med School, 3400 N Broad St, Philadelphia, Pa *Prof of Physiology* (1, 1925)
- Grenell, Robert G, Ph D Johns Hopkins Univ, Dept of Biophysics, Baltimore, Md (1, 1945)
- Griffin, Angus, Ph D George Washington Univ School of Medicine, Dept of Bacteriology, 1335 H St, N W, Washington, D C *Assoc Prof of Bacteriology* (6, 1940)
- Griffith, Fred R, Jr, Ph D Univ of Buffalo Med School, 24 High St, Buffalo, N Y *Prof of Physiology* (1, 1923, 5, 1933)
- Griffith, Wendell H, Ph D Univ of Texas Med School, Galveston *Prof and Chairman of Dept of Biochemistry and Nutrition* (2, 1923, 5, 1934)
- Grimson, Keith S, M D Duke Univ School of Medicine, Durham, N C *Prof of Surgery* (1, 1943, 3, 1949)
- Grindlay, John H, M D Mayo Clinic, Rochester, Minn (1, 1945)
- Groat, Richard A, Ph D Wake Forest College, Bowman Gray School of Medicine, Winston-Salem 7, N C *Assoc Prof of Anatomy* (1, 1945)
- Groat, William A, M D 713 E Genesee St, Syracuse, N Y *Prof of Clinical Pathology, Syracuse Univ College of Medicine* (6, 1917)
- Grodkins, Fred S, Ph D, M D Northwestern Univ Med School, 303 E Chicago Ave, Chicago 11, Ill *Assoc Prof of Physiology* (1, 1945)
- Groedel, Franz M, M D 829 Park Ave, New York City *Research Fellow, Fordham Univ, Biology Dept* (1, 1949)
- Grollman, Arthur, M D, Ph D Southwestern Med College, 2211 Oak Lawn Ave, Dallas, Tex *Prof of Medicine and Chairman of Dept of Exper Medicine, Prof of Pharmacology and Chairman of Dept of Physiology and Pharmacology* (1, 1928, 3, 1933)
- Gross, Erwin G, Ph D, M D State Univ of Iowa, Med Labs, Iowa City *Prof of Pharmacology* (1, 1927, 2, 1923, 3, 1927)
- Gross, Robert E, M D Children's Hosp, 300 Longwood Ave, Boston 15, Mass *Surgeon-in-Chief, Ladd Prof of Children's Surgery* (4, 1940)
- Grossman, Morton Irvin, Ph D, M D Univ of Illinois College of Medicine, Chicago 12 *Assoc Prof of Physiology* (1, 1946)
- Groupé, Vincent, Ph D Rutgers Univ, Dept of Microbiology, New Jersey Agricul Exper Station, New Brunswick *Assoc Prof in Animal Diseases* (6, 1946)
- Gruber, Charles M, M D, Ph D Jefferson Med College, 1025 Walnut St, Philadelphia, Pa *Prof of Pharmacology*, (1, 1914, 3, 1919)
- Gruber, Charles M, Jr, M D Jefferson Med College Hospital, Philadelphia, Pa *Research Fellow in Hematology* (3, 1948)
- Gruhzit, Oswald M, M D Parke, Davis and Co, Research Labs, Detroit, Mich *Research in Pathology and Pharmacology* (4, 1928)
- Grundfest, Harry, Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Assoc in Neurology* (1, 1932)
- Gudernatsch, F, Ph D 41 Fifth Ave, New York City 3 (1, 1930)
- Guerra, Francisco, M Sc, M D Facultad de Medicina, Univ Nacional de Mexico, Mexico, D F *Prof of Pharmacology* (3, 1947)
- Guerrant, N B, Ph D Pennsylvania State College, State College *Prof of Biological Chemistry* (2, 1934, 5, 1933)
- Guest, George Martin, M S, M D Children's Hospital, Cincinnati 29, Ohio *Prof of Pediatrics, Univ of Cincinnati College of Medicine and Grad School* (2, 1933)

- Guest, Maurice Mason, Ph D Wayne Univ College of Medicine, Dept of Physiology, Detroit 26, Mich *Assoc Prof of Physiology* (1, 1946)
- Gulick, Addison, Ph D 308 Westmount Ave, Columbia, Mo *Prof of Physiological Chemistry, Univ of Missouri* (1, 1915, 5, 1933)
- Gunn, Francis D, M D, Ph D Univ of Utah School of Medicine, Salt Lake City *Prof and Head of Dept of Pathology* (4, 1938)
- Gunsalus, Irwin C, Ph D Indiana Univ, Bloomington *Prof of Bacteriology* (2, 1946)
- Gurin, Samuel, Ph D Univ of Pennsylvania School of Medicine, Philadelphia *Prof of Physiological Chemistry* (2, 1938)
- Gustavson, R G, Ph D Univ of Nebraska, Lincoln *Chancellor* (2, 1927)
- Gustus, Edwin L, Ph D Bjorksten Research Lab, 13791 Ave O, Chicago 33, Ill *Vice President* (2, 1934)
- Guterman, Henry S, M D Michael Reese Hospital, Chicago 16, Ill *Asst Dir, Dept of Metabolic and Endocrine Research* (1, 1949)
- Guthrie, Charles Claude, M D, Ph D Univ of Pittsburgh Med School, Pittsburgh, Pa *Prof of Physiology and Pharmacology* (1, 1905, 3, 1909)
- Gutierrez-Noriega, Carlos, M D Facultad de Medicina, Av Grau, Lima, Peru *Prof of Pharmacology* (3, 1948)
- Gutman, Alexander B, M D Columbia Research Service, Welfare Island, New York City 17 *Director* (2, 1947)
- Guttman, Rita M, Ph D Brooklyn College, Brooklyn, N Y *Instr in Physiology* (1, 1946)
- Guyton, Arthur C, M D Univ of Mississippi School of Medicine, Dept of Physiology, University *Acting Chairman, Dept of Physiology* (1, 1949)
- Gyorgy, Paul, M D Univ of Pennsylvania School of Medicine, 3400 Spruce St Philadelphia 4 *Prof of Clinical Pediatrics* (2, 1938, 5, 1939)
- Haag, Harvey B, M D Med College of Virginia, Richmond *Prof of Pharmacology* (3, 1934)
- Haag, J R, Ph D Oregon Agric Exper Station, Corvallis *Chemist* (2, 1947, 5, 1941)
- Haas, Erwin, Ph D Cedars of Lebanon Hospital, Inst for Med Research, Los Angeles 27, Calif *Research Assoc* (2, 1946)
- Haberman, Sol, Ph.D Wm Buchanan Blood, Plasma and Serum Center, Baylor Hospital, Dallas, Tex *Chief of Bacteriology and Serology Services* (6, 1944)
- Hadidian, Zareh, Ph D Tufts College Med School, Boston, Mass (1, 1945)
- Hafkesbring, H Roberta, Ph D Woman's Med College of Pennsylvania, East Falls, Philadelphia *Prof of Physiology* (1, 1931)
- Haggard, Howard W, M D 4 Hillhouse Ave, New Haven, Conn *Dir of Lab of Applied Physiology, Yale Univ* (1, 1919, 2, 1920)
- Hahn, Paul F, Ph D Meharry Med College, Nashville, Tenn *Dir of Cancer Research Labs* (1, 1946, 4, 1939)
- Haig, Charles, Ph D New York Med College, Fifth Ave at 105th St, New York City *Assoc Prof of Physiology and Biochemistry* (1, 1942)
- Haist, Reginald E, M D, Ph D Univ of Toronto, Toronto, Ontario, Canada *Assoc Prof of Physiology* (1, 1943)
- Halbert, Seymour P, M D Columbia Univ College of Physicians and Surgeons, Dept of Ophthalmology, 630 W 168th St, New York City 32 (6, 1947)
- Haldi, John, Ph D Emory Univ School of Dentistry, Emory University, Ga *Prof of Physiology* (1, 1928)
- Hale, Wm M, M D Brookhaven Natl Lab, Upton, L I, N Y *Head, Div of Bacteriology and Virology, Bacteriologist-in-Chief, Brookhaven Natl Lab Hosp* (4, 1941, 6, 1935)
- Haley, Thomas J, Ph D 4133 W 22nd Place, Los Angeles 16, Calif *Chief, Div of Pharmacology and Toxicology, A E Project, Med School, Univ of California* (3, 1949)
- Hall, Charles E, Ph D Univ of Texas, Med Branch, Dept of Physiology, Galveston *Asst Prof* (1, 1949)
- Hall, F G, Ph D Duke Univ School of Medicine, Dept of Physiology and Pharmacology, Durham, N C (1, 1937)
- Hall, George Edward, M D, Ph D Univ of Western Ontario, Ottaway Ave and Waterloo St, London, Ontario, Canada *Dean of the Faculty of Medicine* (1, 1938)
- Hall, Victor E, M A, M D Stanford Univ, Dept of Physiology, Stanford University, Calif *Prof of Physiology* (1, 1934)
- Hall, W Knowlton, Ph D Univ of Georgia School of Medicine, Augusta *Assoc Prof of Biochemistry* (2, 1948)
- Hallenbeck, George Aaron, Ph D, M D Mayo Clinic, Rochester, Minn *Research Assoc* (1, 1946)
- Halliday, Nellie, Ph D Laguna Honda Home, Lab of Exper Oncology, San Francisco, Calif (5, 1933)
- Halpert, Béla, M D Veterans Admin Hospital, 2002 Holcombe Blvd, Houston 4, Texas
- Halstead, Ward C, Ph D, Univ of Chicago, Dept of Medicine, Chicago, Ill *Assoc Prof of Exper Psychology, Div of Psychiatry* (1, 1942)
- Ham, Arthur W, M B Univ of Toronto, Toronto 5, Ontario, Canada *Prof of Anatomy in charge of Histology* (4, 1939)

- Hambourger, Walter E , Ph D , M D G D Searle and Co , P O Box 5110, Chicago, Ill *Chief Pharmacologist* (3, 1934)
- Hamilton, Bengt L K , M D U S Marine Hospital, Staten Island 4, N Y *Med Dir , USPHS* (2, 1925)
- Hamilton, James B , Ph D Long Island College of Medicine, Dept of Anatomy, 350 Henry St Brooklyn 2, N Y (1, 1938)
- Hamilton, Paul B , M D , Ph D Alfred I duPont Inst , Nemours Foundation, Rockland Rd , Wilmington 99, Del *Chief of Biochemistry* (2, 1946)
- Hamilton, Tom S , Ph D Univ of Illinois, 1513 W Clark St , Champaign *Prof and Chief in Animal Nutrition* (2, 1937, 5, 1938)
- Hamilton, W F , Ph D Univ of Georgia School of Medicine, Augusta *Prof of Physiology* (1, 1924)
- Hammett, Frederick S , Ph D 493 Commercial St , Provincetown, Mass *Sr Member Emeritus, Lakenau Hospital Research Inst* (1R, 1920, 2, 1917)
- Hammon, William McD , M D , D P H Univ of Pittsburgh, Pittsburgh, Pa *Prof of Epidemiology, Graduate School of Public Health* (4, 1944, 6, 1946)
- Hampel, C W , Ph D New York Univ College of Medicine, New York City *Assoc Prof of Physiology* (1, 1936)
- Hamre, Dorothy, Ph D Squibb Inst for Med Research, New Brunswick, N J *Research Assoc* (6, 1948)
- Hand, David B , Ph D New York State Agricultural Exper Station, Geneva *Head, Div of Food Science and Technology and Prof of Biochemistry* (2, 1947)
- Handler, Philip, Ph D Duke Univ School of Medicine, Durham, N C *Assoc Prof of Biochemistry and Nutrition* (2, 1944, 5, 1946)
- Handley, Carroll A , Ph D Baylor Univ College of Medicine, 1200 M D Anderson Blvd , Houston 5, Tex *Prof of Physiology and Pharmacology* (3, 1942)
- Haney, Hance F , Ph D , M D Univ of Oregon Med School, Portland *Asst Prof of Medicine* (1, 1939)
- Hanger, Franklin, M D Columbia Univ College of Physicians and Surgeons, 630 W 168th St , New York City 32 *Assoc Prof of Medicine* (6, 1930)
- Hanke, Martin E , Ph D Univ of Chicago, Chicago, Ill *Assoc Prof of Biochemistry* (2, 1925)
- Hanke, Milton Theo, Ph D 7550 S Green St , Chicago, Ill *Research Consultant, Biochemistry and Nutrition* (2, 1919)
- Hanks, John H , Ph D Harvard Univ Med School, Boston, Mass *Dept of Bacteriology, Bacteriologist of the Leonard Wood Memorial* (6, 1935)
- Hansen, Arild E , M D Univ of Texas Med School, Galveston *Prof and Chairman of Dept of Pediatrics, Dir of Univ of Texas Child Health Program* (4, 1941, 5, 1942)
- Hanzal, Ramón F , Ph D Killian Research Labs , 49 W 45th St , New York City *Biochemist* (2, 1935)
- Hanzlik, Paul J , M D Stanford Univ School of Medicine, Sacramento and Webster Sts , San Francisco, Calif *Prof of Pharmacology* (1, 1912, 3, 1912)
- Hardy, James Daniel, Ph D Russell Sage Inst of Pathology, 525 E 68th St , New York City *Research Assoc* (1, 1939)
- Hardy, Mary, D Sc The Brearley School, 610 E 83rd St , New York City *Teacher of Science* (1, 1933)
- Hare, Kendrick, Ph D Children's Hospital, 219 Bryant St , Buffalo 9, N Y (1, 1938)
- Harford, Carl G , M D Washington Univ School of Medicine, St Louis, Mo *Asst Prof of Medicine and Preventive Medicine* (6, 1948)
- Harger, R N , Ph D Indiana Univ School of Medicine, Indianapolis *Prof and Chairman of Dept of Biochemistry and Toxicology* (2, 1938, 3, 1949)
- Harkins, Henry N , Ph D , M D Univ of Washington School of Medicine, Seattle 5 (1, 1942)
- Harmon, Paul M , Ph D Indiana Univ , Bloomington *Prof of Physiology* (1, 1930)
- Harne, O G Univ of Maryland School of Medicine, Baltimore *Assoc Prof of Histology* (1, 1935)
- Harned, Ben King, Ph D Lederle Labs , Pearl River, N Y *Assoc Dir , Pharmacology Research* (2, 1931, 3, 1941)
- Harris, Albert H , M D N Y State Dept of Health, Div of Labs and Research, New Scotland Ave , Albany 1 *Asst Dir for Local Labs* (6, 1937)
- Harris, Albert Sidney, Ph D Baylor Univ College of Medicine, Houston 5, Texas (1, 1939)
- Harris, Milton, Ph D Harris Research Labs , 1246 Taylor St , N W , Washington 11, D C *President* (2, 1939)
- Harris, Paul N , M D Eli Lilly and Company, Indianapolis, Ind *Pathologist, Div of Pharmacology* (3, 1948)
- Harris, Philip L , Ph D Distillation Products, Inc , 755 Ridge Rd W , Rochester 13, N Y *Head of Biochemistry Research Dept , Assoc in Physiology, Univ of Rochester School of Medicine and Dentistry* (2, 1946, 5, 1945)
- Harris, Robert S , Ph D Massachusetts Inst of Technology, Cambridge *Prof of Nutritional Biochemistry* (5, 1941)

- Harris, S C , Ph D Northwestern Univ , Dept of Physiology and Pharmacology, Chicago, Ill *Chairman of Dept* (1, 1947)
- Harris, T N , M D Children's Hospital of Philadelphia, Philadelphia, Pa *Assoc in Pediatrics, Univ of Pennsylvania* (6, 1946)
- Harris, William H , M D Tulane Univ School of Medicine, New Orleans, La *Asst Prof of Pathology and Bacteriology* (4, 1925)
- Harrison, Frank, Ph D Univ of Tennessee College of Medicine, Memphis *Prof and Chief, Div of Anatomy* (1, 1941)
- Harrison, James A , Ph D Temple Univ , Philadelphia 22, Pa *Prof of Biology* (6, 1946)
- Harrison, Ross Granville, M D , Ph D Osborn Zoological Lab , New Haven, Conn *Sterling Prof Emeritus of Biology, Yale Univ* (1, 1906)
- Harrison, R Wendell, M D , Ph D Ellis Ave at 58th St , Chicago 37, Ill *Prof of Bacteriology, Dean of Faculties and Vice Pres , Univ of Chicago* (6, 1934)
- Harrow, Benjamin, Ph D College of the City of New York, Convent Ave and 139th St , New York City *Prof of Chemistry* (2, 1927)
- Hart, E B , B S Univ of Wisconsin Agricultural College, Madison *Prof of Biochemistry* (2, 1910, 5, 1933)
- Hart, E Ross, Ph D Medical Division, Army Chemical Center, Md (3, 1944)
- Hart, William M , Ph D Temple Med School, Broad and Ontario Sts , Philadelphia 40, Pa *Asst Prof of Physiological Chemistry* (1, 1945)
- Hartline, H K , M D Johns Hopkins Univ , Dept of Biophysics, Baltimore 18, Md (1, 1929)
- Hartman, Carl G , Ph D Ortho Research Foundation, Raritan, N J *Dir of Physiology* (1, 1921)
- Hartman, Frank Alexander, Ph D Ohio State Univ , Dept of Physiology, Columbus *Research Prof of Physiology* (1, 1916)
- Hartman, F W , M D Henry Ford Hospital, Detroit, Mich *Pathologist* (4, 1927)
- Hartmann, Alexis F , M D 500 S Kingshighway, St Louis, Mo *Prof of Pediatrics, Washington Univ School of Medicine* (2, 1932)
- Harvey, A McGhee, M D Johns Hopkins Hospital, Baltimore 5, Md *Physician-in-Chief, Prof of Medicine, Johns Hopkins Univ Med School* (1, 1946, 3, 1946)
- Harvey, E Newton, Ph D Princeton Univ , Guyot Hall, Princeton, N J *Henry Fairfield Osborn Prof of Biology* (1, 1914, 2, 1916)
- Hass, George, M D Presbyterian Hospital of Chicago, Chicago, Ill *Prof and Chairman of Dept of Pathology, Univ of Illinois College of Medicine* (4, 1939)
- Hassid, William Z , Ph D , Univ of California, Div of Plant Nutrition, Berkeley *Prof of Plant Nutrition* (2, 1946)
- Hastings, A Baird, Ph D Harvard Med School, 25 Shattuck St , Boston 15, Mass *Hamilton Kuhn Prof of Biological Chemistry* (1, 1927, 2, 1921, 5, 1940)
- Hathaway, Millicent L , Ph D Agricultural Research Administration, Bureau of Human Nutrition and Home Economics, Food and Nutrition Div , Washington 25, D C (5, 1945)
- Hauck, Hazel M , Ph D Cornell Univ , Ithaca, N Y *Prof of Home Economics* (5, 1941)
- Hauge, Siegfred M , Ph D Purdue Univ Agricultural Exper Station, Lafayette, Ind *Research Assoc in Biochemistry* (5, 1933)
- Haurowitz, Felix, M D , D Sc Indiana Univ , Bloomington *Prof of Biochemistry* (2, 1949, 6, 1948)
- Haury, Victor G , M D Box 206, Wellsville, Kansas (3, 1939)
- Haven, Frances L , Ph D Univ of Rochester School of Medicine and Dentistry, 260 Crittenden Blvd , Rochester, N Y *Assoc in Biochemistry* (2, 1941)
- Hawk, Philip B , Ph D Food, Drug and Cosmetic Consultants, 30 Rockefeller Plaza, Room 4631, New York City 20 *Pres of Food Research Labs , Inc* (1, 1903, 2, 1906)
- Hawkins, J E , Jr , Ph D Merck Inst for Therapeutic Research, Rahway, N J *Physiologist* (1, 1943)
- Hawkins, William Bruce, M D Univ of Rochester School of Medicine and Dentistry, 260 Crittenden Blvd , Rochester, N Y *Assoc Prof of Pathology* (4, 1933)
- Hawley, Estelle E , Ph D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Research Fellow in Pediatrics* (5, 1935)
- Hawn, Clinton van Zandt, M D Mary Imogene Bassett Hospital, Cooperstown, N Y *Pathologist, Dir of Otsego County Labs* (4, 1948)
- Hay, Eleanor Clarke, Ph D 7 Greenhill Rd , Madison, N J (1, 1945)
- Hayman, J M , Jr , M D Lakeside Hospital, Cleveland, Ohio *Prof of Clinical Medicine and Therapeutics, Western Reserve Univ* (1, 1928, 3, 1932)
- Haynes, Florence W , Ph D Harvard Med School, 25 Shattuck St , Boston, Mass *Research Assoc in Medicine* (1, 1937)
- Hays, Edwin Everett, Ph.D Armour Labs , 1425 W 42nd St , Chicago 9, Ill *Dir of Biochemical Research* (2, 1946)
- Hays, Harry W , Ph D Wayne Univ College of Medicine, 1512 St Antoine St , Detroit 26, Mich *Assoc Prof of Physiology and Pharmacology* (3, 1949)
- Haythorn, Samuel R , M D Allegheny General Hospital, 320 E North Ave , Pittsburgh, Pa *Dir of William H Singer Memorial Lab* (4, 1925)

- Haywood, Charlotte, Ph D Mount Holyoke College, South Hadley, Mass *Prof of Physiology* (1, 1939)
- Hazen, Elizabeth L, Ph D New York State Dept of Health Labs, 339 E 25th St, New York City *Sr Bacteriologist* (6, 1931)
- Hazleton, Lloyd W, Ph D Box 333, Falls Church, Va *Research Consultant* (3, 1944)
- Hechter, Oscar M, Ph D Worcester Foundation for Exper Biology, 222 Maple Ave, Shrewsbury, Mass (1, 1945)
- Hegnauer, Albert H, Ph D Boston Univ School of Medicine, Boston, Mass *Assoc Prof of Physiology* (1, 1937)
- Hegsted, David Mark, Ph D Harvard School of Public Health, Boston, Mass *Prof of Nutrition* (5, 1944)
- Heidelberger, Michael, Ph D Columbia Univ, 620 W 168th St, New York City 32 *Prof of Immunochemistry, Chemist to the Presbyterian Hospital* (2, 1927, 6, 1935)
- Heilbrunn, Lewis Victor, Ph D Univ of Pennsylvania, Philadelphia *Prof of Zoology* (1, 1930)
- Helm, J William, Ph D 1 Yale Ave, Dayton 6, Ohio Aero-Medical Lab, Army Air Forces, Wright Field *Principal Research Physiologist, Asst in Physiology, Harvard School of Public Health* (1, 1936)
- Heinbecker, Peter, M D Washington Univ Med School, St Louis, Mo *Assoc Prof of Clinical Surgery* (1, 1930)
- Heinle, Robert W, M D Western Reserve Univ, Cleveland, Ohio *Asst Prof of Medicine* (5, 1948)
- Helff, O M, Ph D New York Univ, University Heights, New York City *Assoc Prof of Biology* (1, 1932)
- Hellbaum, Arthur A, Ph D, M D Univ of Oklahoma School of Medicine, Oklahoma City *Prof of Pharmacology* (1, 1937, 3, 1945)
- Hellebrandt, Frances Anna, M D Med College of Virginia, Richmond *Prof of Physical Medicine* (1, 1933)
- Heller, Carl G, M D, Ph D Univ of Oregon Med School, Portland 1 *Assoc Prof of Physiology and Medicine* (1, 1945)
- Heller, Victor G, Ph D Oklahoma A & M College, Stillwater *Head of Dept of Agricultural Chemistry Research* (2, 1935, 5, 1935)
- Hellerman, Leslie, Ph D Johns Hopkins Univ School of Medicine, 710 N Washington St, Baltimore 5, Md *Assoc Prof of Physiological Chemistry* (2, 1935)
- Helmer, Oscar Marvin, Ph D Indianapolis General Hospital, Indianapolis, Ind *Head of Dept of Physiological Chemistry* (2, 1935)
- Hemingway, Allan, Ph D 241 Cecil St, S E, Minneapolis, Minn *Assoc Prof of Physiology, Univ of Minnesota* (1, 1933)
- Henderson, LaVell M, Ph D Univ of Illinois, W A Noyes Lab, Urbana *Asst Prof of Biochemistry* (2, 1949)
- Hendley, Charles D, Ph D Ohio State Univ Dept of Physiology, Hamilton Hall, Columbus 10 *Asst Prof of Physiology* (1, 1949)
- Hendrix, Byron M, Ph D Univ of Texas School of Medicine, Galveston *Prof of Biochemistry* (2, 1920)
- Hendrix, James Paisley, M A, M D Duke Hospital, Durham, N C *Assoc in Medicine (in charge of Therapeutics), Assoc in Physiology and Pharmacology, Duke Univ School of Medicine* (3, 1942)
- Hendry, Jessie L, M A Div of Labs and Research, New York State Dept of Health, New Scotland Ave, Albany *Sr Bacteriologist* (6, 1938)
- Henle, Werner, M D 1740 Bainbridge St, Philadelphia 46, Pa *Assoc Prof of Virology in Pediatrics* (6, 1938)
- Henry, James P, M A, M Sc Aero-Med Lab, Wright Field, Dayton, Ohio On leave of absence from the Univ of Southern California, Los Angeles (1, 1947)
- Henschel, Austin F, Ph D Univ of Minnesota, Minneapolis *Asst Prof of Physiological Hygiene* (1, 1944)
- Hepburn, Joseph Samuel, Ph D, M D Chem D 235 N 15th St, Philadelphia 2, Pa *Prof of Chemistry and Research Assoc in Gastro-enterology, Registrar, Hahnemann Med College and Hospital* (2, 1915)
- Hepler, Opal E, Ph D, M D Northwestern Univ Med School, 303 E Chicago Ave, Chicago, Ill *Assoc Prof of Pathology* (4, 1939)
- Heppel, Leon A, Ph D, M D Natl Insts of Health, 4511 Maple Ave, Bethesda 14, Md *Surgeon, USPHS* (2, 1949)
- Herbst, Robert M, Ph D Kedzie Chemical Lab, Michigan State College, East Lansing *Assoc Prof of Chemistry* (2, 1938)
- Herget, Carl M, Ph D Med Div, Army Chemical Center, Md *Chief, Biophysics Section* (1, 1948)
- Herrick, Julia F, Ph D Mayo Foundation, Rochester, Minn *Assoc Prof of Exper Medicine* (1, 1933)
- Herrin, Raymond C, Ph D, M D Univ of Wisconsin Med School, Madison *Prof of Physiology* (1, 1932)
- Herrington, Lovic P, Ph D 290 Congress Ave, New Haven, Conn *Assoc Dir, John B Pierce Lab of Hygiene, Research Assoc Prof, Dept of Public Health, Yale Med School* (1, 1942)
- Herriott, Roger M, Ph D Johns Hopkins School of Hygiene and Public Health, 615 N Wolfe St, Baltimore 5, Md *Prof of Biochemistry* (2, 1940)

- Hermann, Julian B , Ph B , M D 1185 Park Ave , New York City (3, 1941)
- Herrmann, George K , Ph D , M D Univ of Texas Med Branch, Galveston *Prof of Medicine* (4, 1925)
- Herrmann, Louis George, M D Cincinnati General Hospital, Cincinnati 29, Ohio *Attending Surgeon, Assoc Prof of Surgery, Univ of Cincinnati College of Medicine* (4, 1933)
- Hershey, A D , Ph D Washington Univ School of Medicine, St Louis, Mo *Assoc Prof of Bacteriology and Immunology* (6, 1942)
- Hertz, Roy, Ph D , M D Natl Insts of Health, Bethesda 14, Md *Public Health Surgeon (R), Div of Physiology* (1, 1945)
- Hertz, Saul, M D Radioactive Isotope Foundation, 270 Commonwealth Ave , Boston, Mass *Dir , Instr , Harvard Med School* (4, 1935)
- Hertzman, Alrick B , Ph D St Louis Univ School of Medicine, St Louis, Mo *Prof of Physiology and Dir of Dept* (1, 1925)
- Herwick, Robert P , Ph D , M D American Home Products Corp , 22 E 40th St , New York City *Med Dir , Whitehall Div* (3, 1938)
- Hess, Charles L , M S , M D 308 Davidson Bldg , Bry City, Mich (1, 1916)
- Hess, Walter C , Ph D Georgetown Med School, 39th St and Reservoir Rd , N W , Washington 7, D C *Prof of Biological Chemistry* (2, 1935)
- Hetherington, Albert W , Ph D School of Aviation Medicine, Randolph Field, Texas (1, 1943)
- Hewetson, Jean Hawks, M D 115 E York St , Biglerville, Pa (5, 1944)
- Hewitt, Earl Albon, Ph D Iowa State College, Ames *Assoc Prof of Veterinary Physiology* (1, 1932)
- Hewitt, Julia A W , B A % Emerson H Lillibridge, 8046 Woodlawn Drive, Minneapolis 21, Minn *Sr Technician, Huntington Hospital Lab , Huntington, N Y* (6, 1921)
- Heyroth, Francis F , M D , Ph D Univ of Cincinnati, Cincinnati, Ohio *Assoc Prof of Ind Toxicology and Asst Dir , Kettering Lab , Assoc Prof of Biological Chemistry, College of Medicine* (2, 1935)
- Hiatt, Edwin P , Ph D Univ of North Carolina School of Medicine, Chapel Hill *Assoc Prof of Physiology* (1, 1942)
- Hickman, Kenneth C D , Ph D 56 Thackeray Rd , Rochester 10, N Y *Consultant, Arthur D Little, Inc* (2, 1944)
- Hiestand, William A , Ph D Purdue Univ , Dept of Biology, Lafayette, Ind *Prof of Physiology* (1, 1947)
- Higgins, George M , Ph D Mayo Clinic, Rochester, Minn *Prof of Exper Biology, Mayo Foundation* (5, 1948)
- Higgins, Harold Leonard, M D 322 Franklin St , Newton, Mass (1, 1914, 5, 1933)
- Highman, Benjamin, M D Natl Insts of Health, Bethesda, Md *Surgeon, USPHS, Lab of Pathology and Pharmacology* (4, 1947)
- Hill, Edgar S , Ph D Washington Univ College of Dentistry, St Louis, Mo *Assoc Prof of Biological Chemistry and Physiology* (2, 1936)
- Hill, Robert M , Ph D Univ of Colorado Med Center, 4200 E 9th Ave , Denver *Prof of Biochemistry* (2, 1933)
- Hill, Samuel E , Ph D 18 Collins Ave , Troy, N Y *Research Worker, The Behr-Manning Corp* (1, 1934)
- Hilleman, Maurice, Ph D Army Med Center, AMDR & GS, Dept of Virus and Rickettsial Diseases, Washington 12, D C *Med Bacteriologist* (6, 1949)
- Hiller, Alma, Ph D Presbyterian Hospital, 1753 W Congress St, Chicago 12, Ill *Assoc , Rush Dept of Biochemistry* (2, 1929)
- Himwich, Harold E , M D Fallston, Md *Chief, Clinical Research Branch, Med Div , Army Chem Center, Md* (1, 1925, 5, 1933)
- Himwich, Williamina A , Ph D Johns Hopkins Univ , Welch Med Library, Baltimore, Md (1, 1947)
- Hine, Charles H , Ph D , M D Univ of California Med School, Pharmacology and Toxicology Dept , Med Center, San Francisco 22 *Lecturer in Toxicology, Consulting Pharmacologist and Toxicologist, Shell Development Co* (3, 1947)
- Hines, Harry M , Ph D State Univ of Iowa, Iowa City *Prof of Physiology* (1, 1928)
- Hines, Marion, Ph D Emory Univ Dept of Anatomy, Emory University, Ga *Prof of Exper Anatomy* (1, 1932)
- Hinrichs, Marie, Ph D , M D Southern Illinois Normal Univ , Carbondale *Prof of Physiology, Dir of Student Health Service* (1, 1928).
- Hinsey, Joseph C , Ph D Cornell Univ Med College, 1300 York Ave , New York City *Prof of Anatomy and Dean of the Med College* (1, 1929)
- Hirschmann, Hans, M D , Ph D Lakeside Hospital, Cleveland, Ohio *Asst Prof of Biochemistry, Dept of Medicine, Western Reserve Univ* (2, 1946)
- Hirszfeld, Ludwik, M D Univ of Wroclaw, Wroclaw, Ul Chaubinskiego 4, Poland *Prof of Microbiology, Dir of Med Microbiology* (6, 1946)
- Hisaw, Frederick L , Ph D Harvard Univ Biological Labs , Cambridge, Mass *Prof of Zoology* (1, 1932)
- Hitchcock, David I , Ph D Yale Univ , 333 Cedar St , New Haven 11, Conn *Assoc Prof of Physiology* (2, 1930)
- Hitchcock, Fred A , Ph D Ohio State Univ , Columbus *Prof of Physiology* (1, 1927, 5, 1933)

- Hitchcock, Philip**, Ph D Med College of Alabama, Dept of Physiology and Pharmacology, Birmingham 5 *Asst Prof of Physiology and Pharmacology* (3, 1946)
- Hitchings, George H**, Ph D 50 Primrose Ave, Tuckahoe 7, N Y, *Chief Biochemist, Wellcome Research Labs* (2, 1942)
- Hjort, Axel M**, M D, Ph D P O Box 281, 14 Fern Way, Scarsdale, N Y *Adjunct Physician, Grasslands Hospital, Valhalla, N Y* (2, 1925)
- Hoagland, Hudson**, Ph D 222 Maple Ave, Shrewsbury, Mass *Exec Dir, Worcester Foundation for Exper Biology, Neurophysiologist, Worcester State Hospital* (1, 1932)
- Hobby, Gladys L**, Ph D 11 Bartlett St, Brooklyn 6, N Y *Research Bacteriologist in charge of Biological Control, Chas Pfizer & Co* (6, 1946)
- Hoberman, Henry D**, Ph D, M D Yale Univ School of Medicine, Dept of Physiological Chemistry, 333 Cedar St, New Haven 11, Conn *Asst Prof of Physiological Chemistry* (2, 1949)
- Hodes, Robert**, Ph D Tulane Univ School of Medicine, Dept of Psychiatry, New Orleans 12, La *Prof of Exper Neurology and Neurophysiology* (1, 1941)
- Hodge, Harold Carpenter**, Ph D Univ of Rochester School of Medicine and Dentistry, 260 Crittenden Blvd, Rochester 7, N Y *Prof of Pharmacology and Toxicology* (2, 1937, 3, 1948)
- Hoefler, Paul F A**, Ph D, M D Neurological Inst of New York, 710 W 168th St, New York City 32 *Assoc Prof of Neurology* (1, 1945)
- Hoff, Ebbe Curtis**, Ph D Med College of Virginia, Richmond 19 *Assoc Prof* (1, 1933)
- Hoff, Hebbel E**, Ph D McGill Univ, Montreal, Quebec, Canada *Prof of Physiology* (1, 1933)
- Hoffman, William Samuel**, Ph D, M D Hektoen Inst for Med Research, 629 S Wood St, Chicago 12, Ill *Dir of Biochemistry, Cook County Hospital* (2, 1935)
- Hofmann, Klaus**, Ph D Univ of Pittsburgh Dept of Chemistry, Pittsburgh, Pa *Research Prof* (2, 1947)
- Hogan, Albert G**, Ph D Univ of Missouri, 105 Schweitzer Hall, Columbia *Prof of Animal Nutrition* (2, 1916, 5, 1933)
- Hogness, Thorfin R**, Ph D Univ of Chicago, Chicago Ill *Dir, Inst of Radiobiology and Biophysics* (2, 1941)
- Holck, Harald G O**, Ph D Univ of Nebraska, College of Pharmacy, Lincoln *Prof of Pharmacology* (1, 1935, 3, 1938)
- Hollaender, Alexander**, Ph D Oak Ridge Natl Lab, Oak Ridge, Tenn (1, 1947)
- Hollander, Franklin**, Ph D Mount Sinai Hospital, Fifth Ave and 100th St, New York City *Assoc in Physiology, Head, Gastro-enterology Research Lab* (1, 1942, 2, 1932)
- Hollinshead, W Henry**, Ph D Mayo Clinic, Section on Anatomy, Rochester, Minn *Head of Section on Anatomy, Prof of Anatomy, Mayo Foundation* (1, 1949)
- Holm, August**, Sc D E R Squibb & Sons, New Brunswick, N J *Research Assoc* (6, 1946)
- Holman, Ralph Theodore**, Ph D A and M College of Texas, College Station *Assoc Prof of Biochemistry and Nutrition* (2, 1948)
- Holman, Russell Lowell**, M D Louisiana State Univ School of Medicine, New Orleans *Prof of Pathology* (4, 1940)
- Holmes, Arthur Dunham**, Ph D Univ of Massachusetts, Amherst *Research Prof of Chemistry* (2, 1931, 5, 1933)
- Holmes, Joseph H**, M D, D Med Sc Univ of Colorado School of Medicine, 4200 E Ninth Ave, Denver 7 *Assoc Prof of Medicine* (1, 1947)
- Holmes, Julia O**, Ph D Univ of Massachusetts, 15 Sunset, Amherst *Research Asst of Chemistry Dept* (2, 1942, 5, 1936)
- Holt, Joseph Paynter**, M D, Ph D Standard Oil Co, Room 2400, 30 Rockefeller Plaza, New York City 20 *Dir of Med Research* (1, 1942)
- Holt, L Emmett, Jr**, M D 477 First Ave, New York City 16 *Prof of Pediatrics, New York Univ College of Medicine* (2, 1930, 5, 1946)
- Hoobler, Icie Macy**, Ph D 660 Frederick St, Detroit 2, Mich *Dir, Research Lab Children's Fund of Michigan* (2, 1925, 5, 1933)
- Hoobler, Sibley W**, M D Univ of Michigan Hospital, Dept of Medicine and Surgery, Ann Arbor *Asst Prof of Medicine* (1, 1949)
- Hooker, Davenport**, Ph D Univ of Pittsburgh School of Medicine, Pittsburgh, Pa *Prof of Anatomy* (1, 1920)
- Hooker, Sanford B**, A M, M D 80 E Concord St, Boston, Mass *Member Evans Memorial* (6, 1918)
- Hoover, Sam R**, Ph D 7815 Linden Rd, Philadelphia 18, Pa *Sr Chemist Eastern Regional Research Lab, U S Dept of Agriculture* (2, 1946)
- Hoppert, C A**, Ph D Michigan State College, Box 626, East Lansing *Prof of Biological Chemistry* (5, 1935)
- Hopps, Howard C**, M D Univ of Oklahoma School of Medicine, Dept of Pathology, 801 E 13th St, Oklahoma City *Prof and Chairman of Dept of Pathology* (4, 1947, 6, 1946)
- Horecker, Bernard L**, Ph D Natl Insts of Health, Bethesda 14, Md *Sr Biochemist* (2, 1947)
- Horn, Millard J**, Ph D 1811 Varum St, N E, Washington 18, D C *U.S Dept of Agriculture, Chemist* (2, 1949)
- Horowitz, Norman H**, Ph D California Inst of Technology, Pasadena *Assoc Prof of Biology* (2, 1946)

- Horsfall, Frank L, Jr, M D C M Rockefeller Inst for Med Research, 66th St and York Ave, New York City *Member, Physician to the Hospital of the Rockefeller Inst for Med Research* (6, 1937)
- Horton, Richard G, Ph D Med Div, Army Chemical Center, Md *Acting Chief, Toxicology Section* (1, 1948)
- Horvath, Steven M, Ph D State Univ of Iowa School of Medicine, Dept of Physiology, Iowa City (1, 1943)
- Horwitt, M K, Ph D Biochemical Research Lab, Elgin State Hospital, Elgin, Ill *Dir, Asst Prof, Biological Chemistry, Univ of Illinois College of Medicine* (2, 1941, 5, 1949)
- Hotchkiss, Rollin D, Ph D Rockefeller Inst for Med Research, 66th St and York Ave, New York City *Associate* (2, 1941)
- Hou, H C, M D Inst of Nutrition, Nanking, China *Director*, (5, 1949)
- Houck, C Riley, Ph D Univ of Tennessee Med School, Memphis 3 *Asst Prof in Physiology* (1, 1947)
- Hove, Edwin L, Ph D Alabama Polytechnic Inst, Lab of Animal Nutrition, Auburn *Research Biochemist* (5, 1946)
- Howard, Evelyn, Ph D Johns Hopkins School of Medicine, Baltimore, Md *Asst Prof of Physiology* (1, 1933)
- Howard, John Eager, A B, M D Johns Hopkins Hospital, Baltimore 5, Md *Asst Prof of Medicine* (1, 1946)
- Howard, Marion E, M D New Haven Hospital, New Haven, Conn *Assoc Clinical Prof of Medicine Yale School of Medicine, Assoc Physician, New Haven Hospital and New Haven Dispensary* (4, 1939, 6, 1937)
- Howe, Howard A, Ph D Johns Hopkins Univ, 1901 East Madison St, Baltimore 5, Md *Adjunct Prof of Epidemiology* (6, 1949)
- Howe, Paul E, Ph D U S Dept of Agriculture, Bureau of Animal Ind, Washington 25, D C, *Nutrition Consultant* (1, 1913, 2, 1909, 5, 1933)
- Howe, Percy R, M D, D D S Forsyth Dental Infirmary, Harvard Med School, Boston, Mass *Dir, Prof of Dental Sciences* (5, 1935)
- Howell, Katherine M, M D 6830 S Merrill Ave, Chicago, Ill *Head of Depts of Bacteriology and Serology* (6, 1940)
- Howell, Stacy F, Ph D V D Research Lab, U S Marine Hospital, Stapleton, Staten Island, N Y *Chemist, USPHS* (2, 1940)
- Howland, Joe W, M D, Ph D Strong Memorial Hospital, 260 Crittenden Blvd, Rochester 7, N Y *Asst Prof of Radiation Biology, Univ of Rochester, Chief, Div of Med Services* (1, 1949)
- Hubbard, Roger Sanford, Ph D Univ of Buffalo School of Medicine, 24 High St, Buffalo 2, N Y *Prof of Pharmacology* (1, 1922, 2, 1920)
- Hubbell, Rebecca B, Ph D Connecticut Agricultural Experiment Station, New Haven *Asst Biochemist* (2, 1937, 5, 1935)
- Hudack, Stephen Sylvester, M D 180 Fort Washington Ave, New York City *Assoc Prof of Orthopedic Surgery, Columbia Univ* (4, 1933)
- Huddleston, Ora L, M D, Ph D Kabat-Kaiser Inst, 1815 Ocean Front, Santa Monica, Calif *Med Dir* (1, 1936)
- Hueper, Wilhelm C, M D Natl Cancer Inst, Bethesda, Md *Chief, Cancerogenic Studies Section* (4, 1940)
- Huf, Ernst G, Ph D, M D 3500 Carolina Ave, Richmond, Va *Asst Prof of Physiology, Med College of Virginia* (1, 1949)
- Huff, Jesse W, Ph D Sharp & Dohme, Inc, Glenolden, Pa *Research Biochemist* (2, 1949)
- Huffman, C F, Ph D Michigan State College, East Lansing *Research Prof and Prof in Dairy Husbandry* (5, 1937)
- Huffman, Max N, Ph D Southwestern Med College, 2211 Oak Lawn, Dallas, Tex *Research Prof of Biochemistry* (2, 1947)
- Huggins, Charles Brenton, M D Univ of Chicago, Chicago, Ill *Prof of Surgery* (1, 1932)
- Huggins, Joseph, M D 111 N 49th St, Philadelphia, Pa *Asst Prof of Exper Neurology, Grad School of Medicine, Univ of Pennsylvania, Dir of Lab, Pennsylvania Hospital for Mental Diseases* (1, 1936)
- Huggins, Russell A, Ph D Baylor Univ College of Medicine, 1200 M D Anderson Blvd, Houston 5, Tex *Assoc Prof of Pharmacology* (3, 1949)
- Hughes, Hettie B, Ph D Christ Hospital, Cincinnati 19, Ohio *Research Assoc* (2, 1946)
- Hughes, Josiah Simpson, Ph D Kansas State College, Manhattan *Prof of Chemistry* (2, 1931, 5, 1939)
- Hughes, Thomas P, Ph D Johns Hopkins Univ School of Public Health, Baltimore, Md (6, 1934)
- Hulpieu, Harold R, Ph D Indiana Univ School of Medicine, Indianapolis *Prof of Pharmacology* (3, 1939)
- Hunscher, Helen A, Ph D Western Reserve Univ, 2023 Adelbert Rd, Cleveland 6, Ohio *Head of Dept of Home Economics* (5, 1934)
- Hunter, Andrew, C B E, M B Hospital for Sick Children, Toronto, Ontario, Canada *Consulting Biochemist, Prof Emeritus of Pathological Chemistry, Univ of Toronto* (2, 1908)
- Hunter, Francis Edmund, Jr, Ph D Washington Univ Med School, Dept of Pharmacology, St Louis 10, Mo *Asst Prof of Pharmacology* (2, 1946)
- Hunter, George, M A, D Sc Univ of Alberta, Edmonton, Canada *Prof of Biochemistry* (2, 1924)

- Hunter, Jesse E , Ph D Allied Mills, Inc , 7500 S Adams St , Peoria, Ill *Dir of Research* (5, 1936)
- Hunter, John, Ph D Univ of Michigan, Ann Arbor *Instr in Physiology* (1, 1948)
- Hussey, Raymond, M D Wayne Univ Med Science Center, 1547 Penobscot Building, Detroit 26, Mich *Dir , Inst for Occupational Health Research, Dean and Prof of Occupational Health, School of Occupational Health* (4, 1927)
- Hutchens, John O , Ph D Univ of Chicago, Dept of Physiology, Chicago 37, Ill *Assoc Prof and Chairman of Dept of Physiology, Dir of Toxicity Lab* (1, 1947)
- Hutchings, Brian L , Ph D Lederle Labs Div , American Cyanamid Co , Pearl River, N Y *Research Chemist* (2, 1949)
- Hyman, Chester, Ph D Univ of Southern California School of Medicine, Los Angeles *Asst Prof of Physiology* (1, 1948)
- Ingalls, Mabel S , Ph D Salisbury Mills, Orange County, N Y (6, 1940)
- Ingle, Dwight J , Ph D Upjohn Research Labs , Kalamazoo, Mich *Sr Research Scientist* (1, 1939)
- Ingraham, Raymond Clifford, Ph D Univ of Illinois College of Medicine, 1853 W Polk St , Chicago *Asst Prof in Physiology* (1, 1938)
- Ingram, W R , Ph D State Univ of Iowa College of Medicine, Iowa City *Prof and Head of Dept of Anatomy* (1, 1936)
- Irish, Don D , Ph D Dow Chemical Co , Midland, Mich *Dir , Biochemical Research Lab* (3, 1948)
- Irvin, J Logan, Ph D Johns Hopkins Univ School of Medicine, 710 N Washington St , Baltimore, Md *Asst Prof of Physiological Chemistry* (2, 1942)
- Irving, George Washington, Jr , Ph D U S Dept of Agriculture, Bureau of Agricultural and Industrial Chemistry, South Bldg , Washington 25, D C *Asst Chief* (2, 1946)
- Irving, Laurence, Ph D Swarthmore College, Swarthmore, Pa *Lt Col , A C , Prof of Exper Biology* (1, 1927)
- Irwin, M R , Ph D Univ of Wisconsin, Dept of Genetics, Madison *Prof of Genetics* (6, 1936)
- Isaacs, Raphael, M D 104 S Michigan Ave , Suite 630, Chicago 3, Ill *Attending Physician, Dept of Hematology, Michael Reese Hospital* (4, 1928)
- Isbell, Harris, M D USPHS Hospital, Lexington, Ky *Med Dir , USPHS, Dir , Research Div* (3, 1949)
- Isenberger, R M , M A , M D Univ of Kansas School of Medicine, Kansas City *Prof of Pharmacology* (3, 1937)
- Ivy, A C , Ph D , M D Univ of Illinois, Chicago Professional Colleges, Chicago, Ill *Vice-Pres , Distinguished Prof of Physiology* (1, 1919, 5, 1933)
- Iwamoto, Harry K , Ph D Univ of Maryland School of Medicine, Baltimore *Asst Prof of Pharmacology* (3, 1948)
- Izquierdo, J Joaquin, M D Natl School of Medicine, Mexico City *Prof of Physiology in Natl School of Medicine and the Escuela Medico Militar of Mexico* (1, 1928)
- Jackson, Elizabeth B , A B Army Med Center—AMDR & GS, Dept of Virus and Rickettsial Diseases, Washington 12, D C *Bacteriologist* (6, 1949)
- Jackson, Eugene L , Ph D 1322 W Broad St , Richmond 20, Va *Med Dir , A H Robins Co* (3, 1942)
- Jackson, Richard W , Ph D U S Dept of Agriculture, Northern Regional Research Lab , 825 N University St , Peoria 5, Ill *Head of Fermentation Div* (2, 1930, 5, 1933)
- Jacobs, Merkel Henry, Ph D Univ of Pennsylvania, Philadelphia *Prof of General Physiology* (1, 1919)
- Jacobs, Walter A , Ph D Rockefeller Inst for Med Research, 66th St and York Ave , New York City 21 *Member Emeritus* (2, 1908, 3, 1913)
- Jacobson, Edmund, Ph D , M D Lab for Clinical Physiology, 55 E Washington St , Chicago, Ill (1, 1929)
- Jaffe, Henry L , M D Hospital for Joint Diseases, 1919 Madison Ave , New York City *Dir of Labs* (4, 1925)
- Jahn, Theodore Louis, Ph D Univ of California, Los Angeles 24 *Prof of Zoology* (1, 1944)
- Jailer, Joseph W , Ph D Columbia Univ College of Physicians and Surgeons, New York City *Instr in Medicine* (1, 1948)
- Jamieson, Walter A , Sc D Green Braes, R F D 2, Indianapolis, Ind *Dir , Biological Div , Eli Lilly & Co* (6, 1927)
- Jandorf, Bernard J , Ph D Med Div , Army Chemical Center, Md *Research Biochemist, Biochemistry Section, Lecturer in Preventive Medicine, Johns Hopkins Univ School of Medicine* (2, 1946)
- Janes, Ralph G , Ph D State Univ of Iowa College of Medicine, Iowa City *Assoc Prof of Anatomy* (1, 1948)
- Jansen, Eugene F , B A Enzyme Research Lab , Western Regional Research Lab , Albany 6, Calif *Sr Chemist, Bureau of Agricultural and Industrial Chemistry, U S Dept of Agriculture* (2, 1947)
- Jaques, L B , Ph D Univ of Saskatchewan, Saskatoon Canada *Prof of Physiology* (1, 1943)
- Jasper, Herbert H , Ph D , D s Sci Montreal Neurological Inst , 3801 University St , Mon-

- treal, Quebec, Canada *Lecturer in Neuro-electrography and Dir of Dept of Electrophysiology* (1, 1940)
- Jeans, P C**, M D State Univ of Iowa, Iowa City *Prof of Pediatrics* (5, 1937)
- Jensen, Hans F**, Ph D Med Dept Field Research Lab, Fort Knox, Ky *Chief Biochemist* (2, 1929)
- Jochum, Kenneth E**, Ph D Univ of Kansas, Dept of Physiology, Lawrence (1, 1942)
- Johlin, J M**, Ph D Vanderbilt Univ School of Medicine, Nashville, Tenn *Assoc Prof of Biochemistry* (2, 1928)
- Johnson, B Conner**, Ph D Univ of Illinois, Div of Animal Nutrition, 554 Davenport Hall, Urbana *Assoc Prof* (2, 1947, 5, 1947)
- Johnson, Frank H**, Ph D Princeton Univ, Princeton, N J *Asst Prof, Dept of Biology* (1, 1942)
- Johnson, Joseph L**, Ph D, M D Howard Univ School of Medicine, Washington, D C *Prof and Head of Dept of Physiology* (1, 1934)
- Johnson, J Raymond**, Ph D Univ of Ottawa, Faculty of Medicine, Ottawa, Ontario, Canada (1, 1938)
- Johnson, Marvin J**, Ph D Univ of Wisconsin, Biochemistry Bldg, Madison *Prof of Biochemistry* (2, 1941)
- Johnson, Robert E**, M D, Ph D Univ of Illinois College of Liberal Arts and Sciences, Dept of Physiology, Urbana *Head of Dept* (1, 1944, 2, 1939, 5, 1946)
- Johnson, S R**, Ph D Missouri Farmers Assoc Milling Co, Springfield *Dir of Nutrition* (5, 1947)
- Johnson, Victor**, Ph D, M D Mayo Foundation, Rochester, Minn (1, 1933)
- Johnston, Charles G**, M S, M D Wayne Univ College of Medicine, Detroit, Mich *Prof of Surgery* (1, 1933)
- Johnston, Frances A**, Ph D Cornell Univ, Ithaca, N Y *Asst Prof of Foods and Nutrition* (5, 1948)
- Johnston, Margaret W**, Ph D Box 452, Univ Hospital, Ann Arbor, Mich *Research Assoc in Internal Medicine* (2, 1930, 5, 1938)
- Jolliffe, Norman**, M D 39 75th St, New York City (1, 1932)
- Jones, D Breese**, Ph D U S Dept of Agriculture, Bureau of Human Nutrition and Home Economics, Agricultural Research Admin, Beltsville, Md *Protein Chemist* (2, 1920, 5, 1935)
- Jones, Hardin B**, Ph D Univ of California, Div of Med Physics, Berkeley 4 *Asst Prof of Med Physics and Physiology, Asst Dir of Donner Lab* (1, 1949)
- Jones, James H**, Ph D Univ of Pennsylvania School of Veterinary Medicine, Philadelphia 4 *Prof of Physiological Chemistry* (2, 1928, 5, 1933)
- Jones, Kenneth K**, Ph D Northwestern Univ Med School, 303 E Chicago Ave, Chicago, Ill *Assoc Prof of Physiology and Pharmacology* (1, 1936)
- Joseph, Norman R**, Ph D Univ of Illinois, 1853 W Polk St Chicago 12 *Asst Prof of Chemistry* (2, 1947)
- Joslin, Elliott P**, M A, M D New England Deaconess Hospital, 81 Bay State Rd, Boston, Mass *Dir, George F Baler Clinic* (5, 1933)
- Jukes, Thomas Hughes**, Ph D Lederle Labs, Pearl River, N Y *Head, Dept of Nutrition and Physiology Research* (2, 1935, 5, 1938)
- Jung, Frederic Theodore**, Ph D, M D American Med Assoc, Chicago, Ill *Asst Secretary* (1, 1930)
- Jungeblut, Claus W**, M D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Prof of Bacteriology* 4, 1929, 6, 1926)
- Kabat, Elvin A**, Ph D Columbia Univ College of Physicians and Surgeons, 710 W 168th St, New York City 32 *Assoc Prof of Bacteriology* (2, 1940, 6, 1943)
- Kabat, Herman**, Ph D, M D 2633 16th St, N W, Washington, D C *Consultant in Neurology, Health Dept District of Columbia* (1, 1941)
- Kahn, Reuben L**, Sc D, Univ of Michigan Hospital, Ann Arbor *Assoc Prof of Serology of Syphilis and Chief of Serology Lab* (4, 1934, 6, 1919)
- Kalckar, Herman M**, M D, Ph D Univ of Copenhagen, Inst for Enzyme Research, 28 Juliane Maries Vej, Copenhagen, Denmark *Research Prof* (2, 1942)
- Kalnitsky, George**, Ph D State Univ of Iowa, Iowa City *Asst Prof of Biochemistry* (2, 1948)
- Kamen, Martin D**, Ph D Washington Univ Med School, 510 S Kingshighway, St Louis 10, Mo *Assoc Prof of Chemistry* (2, 1946)
- Kamm, Oliver**, Ph D 365 Lakeshore Drive, Detroit 30, Mich *Research Consultant, Parke, Davis and Co* (2, 1928)
- Kaplan, Nathan O**, Ph D Univ of Illinois College of Medicine Dept of Biological Chemistry, 1853 W Polk St, Chicago 12 *Asst Prof* (2, 1949)
- Karel, Leonard**, Ph D Natl Insts of Health, Div of Research and Fellowships, Bethesda 14, Md *Exec Sec, Hematology and Pharmacology Study Sections, Univ of Maryland School of Medicine, Lecturer in Pharmacology* (3, 1947)
- Karpovich, Peter V**, M D, M P E Springfield College, Springfield, Mass *Prof of Physiology* (1, 1942)
- Karshan, Maxwell**, Ph D Columbia Univ, Dept of Biological Chemistry, 630 W 168th St, New

- York City 32 *Assoc Prof of Biochemistry* (2, 1939)
- Karsner, Howard T, M D Dept of the Navy, Bureau of Medicine and Surgery, Research Div, Washington 25, D C *Med Research Advisor* (4, 1913)
- Katz, Louis Nelson, M A, M D 2900 Ellis Ave, Chicago, Ill *Dir of Cardiovascular Research, Michael Reese Hospital, Professorial Lecturer in Physiology, Univ of Chicago* (1, 1924)
- Katzman, Philip A, Ph D St Louis Univ School of Medicine, 1402 S Grand Blvd, St Louis 4, Mo *Assoc Prof of Biochemistry* (2, 1935)
- Kaulbersz, Jerzy, Ph D M D Collegium Medica, Grzegorzeczka 16, Cracow, Poland *Prof of Physiology* (1, 1944)
- Kaunitz, Hans, M D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Research Assoc in Pathology* (4, 1947)
- Kay, Herbert Davenport, Ph D Natl Inst for Research in Dairying, Shinfield, near Reading, England *Dir, Research Prof of Biochemistry, Univ of Reading* (2, 1930)
- Kazal, Louis Anthony, Ph D Sharp & Dohme, Inc, Med Research Div, Glenolden, Pa *Research Biochemist* (2, 1947)
- Keeton, Robert W, M S, M D Univ of Illinois College of Medicine, 1817 W Polk St, Chicago *Prof of Medicine* (1, 1916, 3, 1924)
- Kehoe, Robert A, M D Univ of Cincinnati College of Medicine, Kettering Lab of Applied Physiology, Eden Ave, Cincinnati, Ohio *Research Prof of Physiology* (1, 1940)
- Keith, Norman M, M D Mayo Clinic, Rochester, Minn *Consulting Physician, Div of Medicine, Mayo Clinic, Prof of Medicine, Mayo Foundation, Univ of Minnesota* (1, 1920, 3, 1932, 4, 1924)
- Keith, T B, Ph D Dept of Animal Husbandry, Univ of Idaho, Moscow, Idaho (5, 1941)
- Kellaway, Peter E, Ph D Baylor Univ College of Medicine, Houston, Texas *Assoc Prof of Neuropsychiatry and Physiology, Dir of Lab of Clinical Electrophysiology* (1, 1947)
- Keller, Allen D, Ph D Field Research Lab, Fort Knox, Ky *Med Dept* (1, 1931)
- Kellner, Aaron, M D Cornell Univ Med College, Dept of Pathology, 1300 York Ave, New York City 21 *Research Assoc in Pathology, Dir of Central Labs, New York Hospital and Cornell Med Center* (4, 1949)
- Kelser, Raymond A, D V M, Ph D The Wyndon, Apt A-105, Wynnewood, Pa *Prof of Bacteriology and Dean of Faculty, School of Veterinary Medicine, Univ of Pennsylvania, Philadelphia* (4, 1932)
- Kelsey, F Ellis, Ph D Univ of Chicago Chicago, Ill *Assoc Prof of Pharmacology* (3, 1941)
- Kelsey, Frances Kathleen O, Ph D Univ of Chicago, Chicago, Ill *Research Assoc (Instr) in Pharmacology* (3, 1941)
- Kemmerer, A R, Ph D Univ of Arizona, Tucson *Head of Dept of Human Nutrition* (5, 1946)
- Kempner, Walter, M D Duke Univ School of Medicine, Durham, N C *Asst Prof of Medicine* (1, 1940)
- Kendall, Edward C, Ph D, 627 Eighth Ave, S W, Rochester, Minn *Prof of Biochemistry, Mayo Foundation, Univ of Minnesota* (1, 1916, 2, 1913, 4, prior to 1920)
- Kendall, Forrest E, Ph D 240-06-53rd Ave, Douglaston, Long Island, N Y *Asst Prof of Biochemistry, Research Service, Columbia Div, Goldwater Memorial Hospital Welfare Island* (6, 1943)
- Kennard, Margaret A, M D Univ of Oregon Med School, Dept of Surgery, Portland *Assoc Prof of Exper Surgery* (1, 1934)
- Kennedy, Cornelia, Ph D 2700 W Robbins St, Minneapolis 10, Minn *Prof Emeritus of Agricultural Biochemistry, Univ of Minnesota* (2, 1924, 5, 1934)
- Kensler, Charles J, Ph D Cornell Univ Med College, 1300 York Ave, New York City 21 *Instr, Dept of Pharmacology, Sr Research Fellow, Natl Research Council* (3, 1949)
- Kent, John F, A M Army Med Center Washington 12, D C *Scientific Dir, Dept of Serology, Army Med Dept Research and Grad School*, (6, 1947)
- Kenton, Harold B, Ph D New England Deaconess Hospital, Boston, Mass *Bacteriologist and Dir of the Blood Bank* (6, 1934)
- Kenyon, Allan T, M D Univ of Chicago, Div of Biological Sciences, 950 E 59th St, Chicago, Ill *Asst Prof of Medicine* (3, 1940)
- Keresztesy, John C, Ph D Natl Insts of Health, Bethesda 14, Md *Scientist Officer Div of Physiology* (2, 1941, 5, 1945)
- Kerr, Stanley E, Ph D American Univ of Beirut, Beirut, Lebanon, Syria *Prof of Biological Chemistry* (2, 1937)
- Kerr, Wm J, M D Univ of California Hospital, 3rd and Parnassus Aves, San Francisco *Physician-in-Chief, Prof of Medicine, Univ of California* (3, 1930)
- Kesten, Homer D, M D Columbia Univ College of Physicians and Surgeons, New York City 32 *Assoc Prof of Pathology* (4, 1931)
- Kety, Seymour S, M D Univ of Pennsylvania Grad School of Medicine, Dept of Physiology and Pharmacology, Philadelphia 4 *Prof of Clinical Physiology* (1, 1949, 3, 1945)
- Keys, Ancel, Ph D Univ of Minnesota, Stadium South Tower, Minneapolis *Prof and Dir of Lab of Physiological Hygiene* (1, 1939, 2, 1936)

- Kidd, John G**, M D Cornell Univ Med College, 1300 York Ave, New York City 32 *Prof of Pathology, Pathologist, New York Hospital* (4, 1937, 6, 1937)
- Kidder, George W**, Ph D Amherst College, Dept of Biology, Amherst, Mass *Prof of Biology* (2, 1949)
- Kies, Marian W**, Ph D Agricultural Research Center, North Bldg, Beltsville, Md *Biochemist, Bur Agri and Indust Chemistry* (2, 1948)
- Kik, M G**, Ph D Univ of Arkansas College of Agriculture, Fayetteville *Assoc Prof of Agricultural Chemistry* (5, 1942)
- Kilborn, Leslie G**, M D, Ph D 47 Warren Rd, Toronto, Ontario, Canada At present West China Union Univ, Chengtu, Sze, China (1, 1928)
- Killian, John Allen**, Ph D Killian Research Labs, Inc, 49 W 45th St, New York City (2, 1921)
- Kinard, F W**, Ph D, M D Med College of the State of South Carolina, Charleston 16 *Assoc Prof of Physiology* (1, 1947)
- King, Barry G**, Ph D Dept of Commerce, Civil Aeronautics Admin, Med Service, Safety Regulations, Washington, D C *Chief, Aeromedical Design and Material Div* (1, 1938)
- King, Charles Edwin**, Ph D Vanderbilt Univ, Nashville, Tenn *Assoc Prof of Physiology* (1, 1916)
- King, Charles Glen**, Ph D Nutrition Foundation Inc, Chrysler Building, New York City *Scientific Dir, Prof of Chemistry, Columbia Univ* 2, 1931, 5, 1933)
- King, Joseph T**, M D, Ph D Univ of Minnesota Med School, 314 Millard Hall, Minneapolis *Assoc Prof of Physiology* (1, 1931)
- Kirch, Ernst R**, Ph D Univ of Illinois College of Pharmacy, 808 S Wood St, Chicago 12, Ill *Assoc Prof of Chemistry* (2, 1948)
- Kirchhof, Anton C**, M S, M D Univ of Oregon Med School, Dept of Pharmacology, Portland 1 *Research Assoc* (3, 1947)
- Kirk, Paul L**, Ph D Univ of California, Berkeley *Prof of Biochemistry* (2, 1933)
- Kirkbride, Mary B**, Sc D 314 State St, Albany 6, N Y (6, 1921)
- Kirschbaum, Arthur**, M D, Ph D Univ of Minnesota Med School, Minneapolis *Assoc Prof of Anatomy* (4, 1948)
- Kisch, Bruno**, M D Yeshiva Univ, New York City *Prof of Biochemistry* (1, 1943)
- Kleiber, M**, D Sc Univ of California, Davis *Prof of Animal Husbandry* (1, 1943, 5, 1933)
- Klein, J Raymond**, Ph D Brookhaven Natl Lab, Upton, L I, N Y *Sr Biochemist, Dept of Biology* (2, 1941)
- Kleiner, Israel Simon**, Ph D New York Med College and Flower Hospital, New York City 29 *Prof of Physiology and Biochemistry* (1, 1911, 2, 1912, 3R, 1912, 5, 1933)
- Kleitman, Nathaniel**, Ph D Univ of Chicago, Chicago, Ill *Assoc Prof of Physiology* (1, 1923)
- Klemperer, Friedrich Wilhelm**, M D Trudeau Foundation, Trudeau, N Y *Head of Dept of Biochemistry* (2, 1941)
- Kletzien, Seymour W**, Ph D 330 S Ninth St, Philadelphia, Pa Nutrition Research Clinic, Philadelphia Lying-In and Pennsylvania Hospitals *Biochemist* (5, 1933)
- Kline, O L**, Ph D Federal Security Agency, Food and Drug Admin, Washington, D C *Biochemist* (5, 1936)
- Kline, Raymond F**, M S R F D 1, Charlottesville, Va (1, 1946)
- Klotz, Irving M**, Ph D Northwestern Univ, Dept of Chemistry, Evanston, Ill *Assoc Prof of Chemistry* (2, 1947)
- Kluver, Heinrich**, Ph D Univ of Chicago, Chicago, Ill *Prof of Exper Psychology* (1, 1935)
- Knight, C Arthur**, Ph D Univ of California, Virus Lab, Berkeley 4 *Assoc Prof* (2, 1946)
- Knisely, Melvin H**, Ph D Med College of South Carolina, Dept of Anatomy, Charleston *Chairman of Dept of Anatomy* (1, 1949)
- Knoefel, Peter K**, M A, M D Univ of Louisville, 101 W Chestnut St, Louisville, Ky *Prof of Pharmacology* (3, 1934)
- Knowlton, G Clinton**, Ph D Emory Univ, Room 101, Physiology Bldg, Emory University, Ga (1, 1938)
- Knox, Eugene W**, M D 3026 S California Ave, Chicago 8, Ill *Research Associate, Rheumatic Fever Research Inst, Northwestern Univ Med School* (2, 1948)
- Knudson, Arthur**, Ph D Albany Med College, New Scotland Ave, Albany, N Y *Prof of Biochemistry and Assoc Dean* (2, 1919, 5, 1936)
- Knutti, Ralph Eddy**, M D Children's Hospital, Los Angeles, Calif *Dir of Labs, Asst Prof of Pathology, Univ of Southern California* (4, 1933)
- Kober, Philip A**, B S Sherman Labs, Detroit, Mich *Dir of Research* (2, 1912)
- Kobrak, Heinrich G**, Ph D Univ of Chicago, Chicago, Ill *Asst Prof of Surgery* (1, 1948)
- Kochakian, Charles D**, Ph D Univ of Rochester School of Medicine and Dentistry, Rochester 7, N Y *Assoc Prof of Physiology* (1, 1942, 2, 1948)
- Kocher, Rudolph Alfred**, M D Box 936, Carmel, Calif *Dir of Velie Metabolic Clinic* (2, 1915)
- Koehler, Alfred E**, M D, Ph D 317 W Pueblo St, Santa Barbara, Calif *Physician, Sansum Clinic, Santa Barbara Cottage Hospital* (2, 1924)
- Koehn, Carl J**, Ph D Surgeon General's Office, Preventive Medicine Div, Washington, D C *Chief, Nutrition Branch* (5, 1949)

- Koehn, Martha, Ph D 285 15th Ave, Apt 22, Columbus, Ohio *Nutritionist, Ohio State Dept of Health* (5, 1933)
- Koelle, George B, Ph D Johns Hopkins Hospital, Wilmer Inst, Baltimore, Md *Chalfont Fellow in Ophthalmology* (3, 1947)
- Koepf, George F, M D 537 Delaware Ave, Buffalo 2, N Y *Assoc in Physiology, Univ of Buffalo* (1, 1942)
- Koerber, Walter L, Ph D E R Squibb and Sons, New Brunswick, N J *Asst Dept Head* (6, 1943)
- Kohlstaedt, Kenneth G, M D Lilly Lab for Clinical Research, Indianapolis General Hospital, Indianapolis 7, Ind *Director* (1, 1947)
- Kohn, Henry I, Ph D, M D Univ of California Hospital, Radiology Dept, San Francisco *Surgeon, USPHS* (1, 1940)
- Kolmer, John A, M S, M D, D P H 1 Montgomery Ave, Bala-Cynwyd, Pa *Prof of Medicine, Temple Univ, Dir, Research Inst of Cutaneous Medicine* (6, 1913)
- Komarov, Simon A, M D, Ph D S S Fels Fund Med Research Lab, 255 S 17th St, Philadelphia, Pa *Dir of Dept of Biochemistry, Temple Univ School of Medicine* (1, 1933)
- Kopeloff, Nicholas, Ph D New York State Psychiatric Inst, 722 W 168th St, New York City *Principal Research Bacteriologist, New York State Psychiatric Inst and Hospital* (6, 1937)
- Koppanyi, Theodore, Ph D Georgetown Univ, Washington D C *Prof of Pharmacology* (1, 1924, 3, 1935)
- Koprowski, Hilary, M D Lederle Labs Div, American Cyanamid Co, Pearl River, N Y *Asst Dir, Viral and Rickettsial Research* (6, 1946)
- Kornberg, Arthur, M D Natl Insts of Health, Bethesda 14, Md *Sr Surgeon* (2, 1949)
- Korr, Irwin M, Ph D Kirksville College of Osteopathy and Surgery, Kirksville, Mo *Prof of Physiology* (1, 1939)
- Kosman, A J, Ph D Northwestern Univ Med School, Dept of Physiology, 303 E Chicago Ave, Chicago 11, Ill *Asst Prof* (1, 1949)
- Koster, Rudolf, Ph D Tulane Univ, Dept of Pharmacology, Station 20, New Orleans, La *Instr, Dept of Pharmacology, School of Medicine* (3, 1949)
- Kottke, Frederic J, Ph D, M D Univ of Minnesota, Minneapolis *Baruch Fellow in Physical Medicine* (1, 1947)
- Kozelka, Frank L, Ph D Univ of Wisconsin, Dept of Pharmacology and Toxicology, Madison *Assoc Prof of Toxicology* (3, 1939)
- Krahl, Maurice E, Ph D Washington Univ School of Medicine, St Louis 10, Mo *Asst Prof of Pharmacology* (2, 1939, 3, 1949)
- Krakower, Cecil Alexander, M D Univ of Illinois College of Medicine, 1853 West Polk St, Chicago *Prof of Pathology* (4, 1945)
- Kramer, Benjamin, A M, M D 60 Plaza St, Brooklyn 17, N Y *Pediatrician-in-Chief, Brooklyn Jewish Hospital, Prof of Clin Pediatrics, Long Island College Med School* (1, 1915, 2, 1914)
- Kramer, Martha, Ph D Kansas State College, Manhattan *Asst Dean, School of Home Economics* (5, 1933)
- Kramer, S D, M D, Ph D 192 Washington Sq, Salem, Mass *Virologist* (6, 1944)
- Krampitz, Lester O, Ph D Western Reserve Univ, 2109 Adelbert Rd, Cleveland 6, Ohio *Head, Dept of Microbiology* (2, 1946, 6, 1949)
- Krantz, John C, Jr, Ph D Univ of Maryland Med School, Baltimore *Prof of Pharmacology* (3, 1937)
- Kratzer, F H, Ph D Univ of California, Div of Poultry Husbandry, Davis *Asst Prof* (5, 1949)
- Krauss, William E, Ph D Ohio Agricultural Exper Station, Wooster *Assoc Dir* (2, 1932, 5, 1933)
- Kraybill, Henry R, Ph D 5720 Woodlawn Ave, Chicago 37, Ill *Professorial Lecturer, Dept of Biochemistry, Univ of Chicago, Dir, Dept of Scientific Research, American Meat Inst Foundation* (2, 1942)
- Krayer, Otto, M D Harvard Med School, 25 Shattuck St, Boston, Mass *Assoc Prof of Comparative Pharmacology* (3, 1938)
- Kreezer, George L, Ph D Washington Univ, St Louis 10, Mo *Assoc Prof of Psychology* (1, 1948)
- Krehl, Willard A, Ph D Yale Univ, 333 Cedar St, New Haven, Conn *Asst Prof of Nutrition* (2, 1947, 5, 1949)
- Krop, Stephen, Ph D Warner Inst, Dept of Pharmacology, 113 W 18th St, New York City (1, 1949, 3, 1944)
- Krueger, Albert Paul, M D Univ of California, Berkeley *Prof and Chairman, Dept of Bacteriology, Dir, Office of Naval Research Task V* (4, 1930, 6, 1937)
- Krueger, Hugo M, Ph D Oregon State College, Dept of Zoology, Corvallis *Prof of Physiology* (1, 1931, 3, 1935)
- Krumbhaar, Edward B, M D, Ph D Univ of Pennsylvania Med School, Philadelphia *Prof Emeritus of Pathology* (1R, 1914, 4, prior to 1920)
- Kruse, Harry Dayton, M D, Sc D Milbank Memorial Fund, 40 Wall St, New York City (2, 1933)
- Kruse, Theophile K, Ph D Univ of Pittsburgh Med School, Pittsburgh, Pa *Prof of Physiology and Pharmacology* (1, 1919, 3, 1920)
- Kubicek, William G, Ph D Univ of Minnesota Hospitals, Div of Physical Medicine, Minneapolis *Assoc Prof* (1, 1947)

- Kubie, Lawrence S**, M D 7½ E 81st St, New York City 29 *Clin Prof of Psychiatry and Mental Hygiene, Yale Univ School of Medicine* (4, 1928)
- Kuffler, Stephen W**, M D Johns Hopkins Med School, Wilmer Inst, Baltimore 5, Md *Assoc Prof of Physiological Optics* (1, 1949)
- Kuhn, Harry A**, M S 3915 Fulton St N W, Washington, D C *Colonel, C W S, War Dept, Executive Officer, C W Procurement District* (3, 1927)
- Kuhn, L Roland**, Ph D Army Medical Center, AMDR GS, Washington 12, D C *Chief, Dept of Bacteriology* (6, 1939)
- Kuizenga, Marvin H**, Ph D Upjohn Company, Kalamazoo, Mich *Head of Dept of Pharmacology-Endocrinology* (2, 1947)
- Kun, Ernest**, M D Tulane Univ, Dept of Medicine, 1430 Tulane Ave, New Orleans 12, La *Asst Prof* (3, 1949)
- Kunde, Margarete M**, Ph D, M D 30 N Michigan Ave, Suite 1308, Chicago, Ill *Instr in Medicine, Northwestern Univ Med School, Clin Asst in Endocrinology, Cook County Hospital* (1, 1924)
- Kuntz, Moses**, Ph D Rockefeller Inst for Med Research, Princeton, N J *Assoc Member* (2, 1947)
- Kurotchkin, Timothy J**, M D 156 Forest Ave, Pearl River, N Y *Bacteriologist* (6, 1946)
- Kurtz, Alton C**, Ph D Univ of Oklahoma Med School, Dept of Biochemistry, Oklahoma City *Assoc Prof* (2, 1942)
- Kuyper, Adrian C**, Ph D Wayne Univ College of Medicine, Detroit 26, Mich *Asst Prof of Physiological Chemistry* (2, 1946)
- Kydd, David M**, M D Yale Univ School of Medicine, New Haven, Conn *Assoc Prof of Medicine* (5, 1934)
- Kyker, Granvil C**, Ph D Univ of North Carolina School of Medicine, Dept of Biological Chemistry and Nutrition, Chapel Hill *Assoc Prof* (2, 1947)
- LaBelle, Annette, B A** Grasslands Hospital, Valhalla, New York (1, 1948)
- Lackey, Robert W**, Ph D Southwestern Med College, Dept of Physiology and Pharmacology, Dallas 4, Texas *Prof of Physiology* (1, 1947)
- Lacorte, Jose G**, M D Instituto Oswaldo Cruz, Rio de Janeiro, Brazil, S A *Dir, Virus Section, Oswaldo Cruz Inst* (6, 1946)
- Lacy, G R**, M D Univ of Pittsburgh, Pittsburgh, Pa *Prof of Bacteriology and Immunology* (4, 1927)
- Lahch, Joseph J**, M D Univ of Wisconsin, Dept of Pathology, 426 N Charter St, Madison 6 *Asst Prof of Pathology* (4, 1946)
- Lamb, Alvin R**, Ph D Hawaiian Sugar Planters' Assoc, Exper Station, Honolulu *Research Assoc* (2, 1923, 5, 1934)
- Lambert, Edward H**, Ph D, M D Mayo Foundation, Rochester, Minn *Asst Prof of Physiology* (1, 1945)
- Lambert, Robert A**, M D Bricks Springs, Greensboro, Ala *Consultant for Fellowship Section, Pan American Sanitary Bureau, Regional Office of World Health Organization* (4, 1922)
- Lambertsen, Christian J**, M D Univ of Pennsylvania, Philadelphia, Pa *Asst Prof of Pharmacology, Assoc in Medicine* (3, 1948)
- Lampen, J Oliver**, Ph D 1530 Rydalmount Rd, Cleveland Heights, Ohio *Assoc Prof of Microbiology, Western Reserve Univ School of Medicine* (2, 1947)
- Lamport, Harold, M D** Yale Univ School of Medicine, New Haven, Conn *Assoc Prof of Physiology* (1, 1943)
- Lamson, Paul Dudley**, M D Vanderbilt Univ Med School, Nashville, Tenn *Prof of Pharmacology* (1, 1921, 3, 1915)
- Lancefield, Rebecca C**, Ph D 66th St and York Ave, New York City 21 *Assoc Member, Rockefeller Inst for Med Research* (6, 1933)
- Landis, Carney**, Ph D Columbia Univ, Psychiatric Inst, 722 W 168th St, New York City *Principal Research Psychologist and Prof of Psychology* (1, 1939)
- Landis, Eugene Markley**, Ph D, M D Harvard Med School, Dept of Physiology, 25 Shattuck St, Boston, Mass *George Higginson Prof of Physiology* (1, 1928)
- Landowne, Milton**, M D 6101 Stewart Ave, Baltimore 9, Md (1, 1947)
- Lands, Alonzo, M**, Ph D Sterling-Winthrop Research Inst, Rensselaer, N Y *Head, Pharmacology Section* (1, 1942, 3, 1947)
- Lange, Carl**, M D 371 Morris St, Albany, N Y *Assoc Bacteriologist, Divs of Labs and Public Health, N Y State Dept of Health* (6, 1938)
- Langley, Wilson D**, Ph D Univ of Buffalo Med School, 24 High St, Buffalo, N Y *Prof of Biochemistry* (2, 1937)
- Langworthy, Orthello R**, M A, M D Johns Hopkins Hospital, Baltimore, Md *Assoc Prof of Psychiatry, Johns Hopkins Univ* (1, 1928)
- Lanni, Frank**, Ph D Duke Univ School of Medicine, Durham, N C *Research Assoc* (6, 1949)
- Lardy, Henry A**, Ph D Univ of Wisconsin, Dept of Biochemistry, Madison 6 *Assoc Prof* (2, 1946, 5, 1949)
- Larrabee, Martin G**, Ph D Johns Hopkins Univ, Biophysics Dept, Baltimore 18, Md (1, 1940)
- Larsen, Eleanor M**, Ph D Univ of Wisconsin, Dept of Physiology, S M I, Madison 6 *Instr in Physiology* (1, 1949)
- Larson, Carl L**, M D Natl Insts of Health, Div of Infectious Diseases, Bethesda, Md *Surgeon, USPHS* (6, 1948)

- Larson, Edward, Ph D Univ of Miami, Miami, Fla *Prof of Physiology and Pharmacology* (1, 1929, 3, 1937)
- Larson, Hardy W, Ph D Metropolitan Life Insurance Co, Biochemical Lab, 1 Madison Ave, New York City *Research Chemist* (2, 1937)
- Larson, Paul S, Ph D Med College of Virginia, Richmond *Assoc Prof of Research Pharmacology* (1, 1939, 3, 1947)
- Lashley, K S, Ph D Yerkes Labs, Orange Park, Fla *Research Prof of Neuropsychology, Harvard Univ, Dir, Yerkes Labs of Primate Biology, Inc* (1, 1923)
- Laskowski, M, Ph D Marquette Univ Med School, Milwaukee 3, Wis *Assoc Prof of Biochemistry* (2, 1944)
- Last, Jules H, Ph D, M D Univ of Illinois College of Medicine, Chicago *Asst Prof of Pharmacology* (3, 1948)
- Lauffer, Max A, Jr, Ph D Univ of Pittsburgh, Pittsburgh 13, Pa *Research Prof, Dept of Physics and Physiological Chemistry* (2, 1946)
- Laug, E P, Ph D Food and Drug Admin, Div of Pharmacology, 12th and C Sts S W, Washington 25, D C *Sr Pharmacologist* (2, 1938, 3, 1947)
- Lauson, Henry D, Ph D, M D Rockefeller Inst, 66th St and York Ave, New York City 21 *Associate* (1, 1946)
- Lavine, T F, Ph D Lankenau Hospital Research Inst, Philadelphia, Pa *Research Chemist* (2, 1938)
- Lawrence, W Sherwood, M D 906 Hazel St, Gridley, Calif (3, 1944)
- Lawson, Hampden, M D, Ph D Univ of Louisville, Louisville, Ky *Prof of Physiology* (1, 1933)
- Lawton, Alfred H, M D, Ph D Veterans Admin, Bureau of Medicine and Surgery, Washington, D C *Chief, Research Div* (1, 1949, 3, 1948)
- Leake, Chauncey D, Ph D Univ of Texas Med Branch, Galveston, *Vice-Pres of Univ of Texas in Charge of Med Program* (1, 1923, 3, 1924)
- Leatham, James H, Ph D Rutgers Univ, New Brunswick, N J *Prof of Zoology* (1, 1945)
- Leathes, John Beresford, M A, M B Westfield Ware Lane, Lyme Regis, Dorset, England (2, 1909)
- Lederer, Ludwig George, Ph D, M D Pennsylvania Central Airlines, Natl Airport, Washington, D C, *Med Dir* (1, 1940)
- Lee, Douglas H K, M D Johns Hopkins Univ, I Bowman School of Geography, Baltimore 18, Md *Prof of Physiological Climatology, Lecturer in Physiological Hygiene* (1, 1949)
- Lee, Milton O, Ph D 2101 Constitution Ave, Washington 25, D C *Exec Sec and Managing Editor, American Physiological Society, Federation Sec* (1, 1927, 5, 1933)
- Leese, Chester E, Ph D George Washington Univ School of Medicine, Washington, D C *Assoc Prof of Physiology* (1, 1934)
- Lehman, Arnold J, Ph D, M D Food and Drug Admin, Washington 25, D C *Chief, Div of Pharmacology* (3, 1937)
- Lehman, Robert A, Ph D New York Univ College of Medicine, 477 First Ave, New York City *Instr in Therapeutics* (3, 1942)
- Lehmann, Gerhard, M D, Dr Ing Scientific Dept, Hoffmann-LaRoche, Nutley 10, N J *Pharmacologist* (3, 1939)
- Lehninger, Albert L, Ph D Univ of Chicago Med School, 950 E 59th St, Chicago 37, Ill *Asst Prof of Biochemistry in Depts of Biochemistry and Surgery* (2, 1946)
- Lehr, David, M D New York Med College, Flower and Fifth Ave Hospitals, Fifth Ave at 105th St, New York City 29 *Asst Prof of Pharmacology* (3, 1947)
- Leichsenring, Jane M, Ph D Univ of Minnesota, Univ Farm, St Paul *Prof of Nutrition* (5, 1948)
- Leimdorfer, Alfred, M D Univ of Illinois College of Medicine, Dept of Psychiatry, Chicago 12 *Assoc Prof* (1, 1947)
- Lein, Allen, Ph D Northwestern Univ Med School, Dept of Physiology, Chicago 11, Ill *Physiologist* (1, 1946)
- Lenhart, Carl H, M D Lakeside Hospital, 2065 Adelbert Rd, Cleveland, Ohio *Oliver H Payne Prof of Surgery, Western Reserve Univ* (1, 1921)
- Lennette, Edwin H, Ph D, M D California State Dept of Public Health, Berkeley *Dir, Viral and Rickettsial Disease Lab* (4, 1941, 6, 1947)
- Leonard, Clifford Shattuck, Ph D 87 Oxford Rd, Longmeadow, Springfield, Mass, Yale Univ Med School, New Haven, Conn *Technical Assoc, Chemical-Biological Coordination Center, Natl Research Council* (3, 1927)
- Leonards, Jack Ralph, Ph D Western Reserve Univ, Cleveland, Ohio *Asst Prof of Biochemistry* (2, 1948)
- Le Page, G A, Ph D Univ of Wisconsin, McArdle Memorial Lab for Cancer Research, Madison 6 *Asst Prof of Oncology* (2, 1949)
- Lepkovsky, Samuel, Ph D Univ of California, Poultry Div, Berkeley 4 *Prof of Poultry Husbandry* (2, 1933, 5, 1933)
- L'Esperance, Elise L, M D 2 East 61st St, New York City *Dir, Strong Cancer Precaution Clinic, Memorial Hospital, and New York Infirmary* (6, 1920)
- Leverton, Ruth M, Ph D Univ of Nebraska, Dept of Home Economics, Lincoln *Assoc Prof of Human Nutrition Research* (5, 1942)
- Levin, Louis, Ph D Columbia Univ, College of Physicians and Surgeons, 630 W 168th St,

- New York City 32 *Asst Prof of Anatomy* (2, 1939)
- Levine, Harold**, Ph D 941 E Sylvan Ave, Milwaukee 11, Wis (2, 1933, 5, 1933)
- Levine, Milton**, Ph D Inst of Exper Medicine, College of Med Evangelists, 312 N Boyle Ave, Los Angeles, Calif *Assoc Dir, Inst of Exper Medicine* (6, 1942)
- Levine, Philip**, M D Ortho Research Foundation, Raritan, N J *Dir, Biologic Div* (6, 1925)
- Levine, Rachmiel**, M D Michael Reese Hospital, Chicago, Ill *Acting Dir, Dept of Metabolic Research, Professorial Lecturer in Physiology, Univ of Chicago* (1, 1942)
- Levine, Samuel Z**, M D, New York Hospital, 525 E 68th St, New York City *Prof of Pediatrics, Cornell Univ Med College, Pediatrician-in-Chief, New York Hospital* (5, 1933)
- Levine, Victor Emanuel**, Ph D, M D Creighton Univ School of Medicine, Omaha, Nebr *Prof of Biological Chemistry and Nutrition* (2, 1936)
- Levinson, Samuel A**, Ph D, M D Univ of Illinois College of Medicine, 808 S Wood St, Chicago *Prof of Pathology, Dir of Labs, Research and Educational Hospital* (4, 1938)
- Levison, Louis A**, M D 421 Michigan St, Toledo, Ohio *Physician to Toledo and St Vincent Hospitals* (6, 1916)
- Levy, Milton**, Ph D New York Univ College of Medicine, 477 First Ave, New York City *Assoc Prof of Chemistry* (2, 1933)
- Levy, Robert L**, M D 730 Park Ave, New York City *Prof of Clin Medicine, Columbia Univ College of Physicians and Surgeons* (3, 1915)
- Lewey, F H**, M D 3400 Spruce St, Philadelphia 4, Pa *Prof of Neuroanatomy, Univ of Pennsylvania Grad School of Medicine, Assoc in Neuropathology and Neurosurgery, Med School* (1, 1937)
- Lewis, George T**, Ph D Emory Univ School of Medicine, Dept of Biochemistry, Emory Univ, Ga *Assoc Prof* (2, 1949)
- Lewis, Gladys Kinsman**, Ph D 401 S Lafayette St, Denver 9, Colo (5, 1944)
- Lewis, Howard Bishop**, Ph D Univ of Michigan Med School, Ann Arbor *John Jacob Abel Univ Prof of Biological Chemistry* (1, 1925, 2, 1913, 5, 1933)
- Lewis, James C**, Ph D U S Dept of Agriculture, Western Regional Research Lab, Albany 6, Calif *Biochemist* (2, 1946)
- Lewis, Jessica H**, M D Univ of North Carolina School of Medicine, Dept of Physiology, Chapel Hill *Research Assoc* (1, 1949)
- Lewis, Julian Herman**, M D 4750 Champlain Ave, Chicago, Ill *Assoc Prof of Pathology, Univ of Chicago, Member, Otho S A Sprague Memorial Inst* (4, 1924)
- Lewis, Lena A**, Ph D Cleveland Clinic, Euclid Ave and E 93rd St, Cleveland 6, Ohio *Research Staff* (1, 1946)
- Lewis, Robert C**, Ph D 4200 E 9th Ave, Denver, Colo *Prof of Biochemistry, Univ of Colorado School of Medicine* (2, 1931, 5, 1933)
- Ley, Herbert Leonard, Jr**, M D Army Medical Center, AMDR & GS, Dept Virus and Rickettsial Diseases, Washington 12, D C *Assistant* (6, 1949)
- Li, Choh Hao**, Ph D Univ of California, 4596 Life Sciences Bldg, Berkeley *Assoc Prof of Exper Biology* (2, 1944)
- Li, Richard C**, M D c/o Dr T S Yu, 392 MaDang Rd, Shanghai 25, China *Guest in Dept of Pharmacology, Natl Med College of Shanghai* (3, 1941)
- Libby, Raymond L**, Ph D Veterans Admin, Wilshire and Sawtelle Blvds, Los Angeles 25, Calif *Assoc Prof of Radio Biology, Univ of California Med School, Chief of Isotope Section, Veterans Hospital, Los Angeles* (6, 1938)
- Liberson, W T**, M D Inst of Living, Hartford, Conn *Neurophysiologist* (1, 1948)
- Libet, Benjamin**, Ph D Univ of California Med Center, Dept of Anatomy, San Francisco *Asst Prof of Physiology, Med School* (1, 1942)
- Licklider, J C R**, Ph D Harvard Univ, Psycho-Acoustic Lab, Cambridge, Mass *Lecturer in Psychology* (1, 1948)
- Liddell, Howard S**, Ph D Cornell Univ, Ithaca, N Y *Prof of Psychology* (1, 1925)
- Lieb, Charles C**, M D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City *Hosack Prof of Pharmacology* (1R, 1936, 3, 1915)
- Lieberman, Arnold L**, M D, Ph D 328 No Country Club Rd, Tucson, Ariz (1, 1934)
- Lieberman, Seymour**, Ph D Sloan-Kettering Inst, 444 E 68th St, New York City 21 *Associate* (2, 1948)
- Lifson, Nathan**, M D, Ph D 617 Kenwood Parkway, Minneapolis, Minn *Prof of Physiology, Univ of Minnesota Med School* (1, 1944)
- Lightbody, Howard D**, Ph D QM Food and Container Inst for the Armed Forces, 1849 W Pershing Rd, Chicago 9, Ill *Dir of Food Labs* (2, 1936)
- Ligon, Edgar Williams, Jr**, Ph D Production and Marketing Admin, Insecticide Div, Agriculture Bldg, Washington, D C (3, 1948)
- Lilienthal, Joseph L, Jr**, M D Johns Hopkins Hospital, Baltimore 5, Md *Assoc Prof of Medicine* (1, 1945)
- Lillie, Ralph Stayner**, Ph D Physiological Labs, Univ of Chicago, Chicago 37, Ill *Prof Emeritus of Physiology* (1R, 1905, 2, 1913)
- Lillie, R D**, M D Pathology Lab, Natl Insts

- of Health, Bethesda, Md *Chief Med Dir, USPHS* (4, 1941)
- Lim, Robert Kho-Seng, Ph D Academia Sinica, 320 Yo Yang Rd, Shanghai, China *Dir of Inst of Medicine* (1, 1923)
- Lindeman, V F, Ph D Syracuse Univ, 16 Lyman Hall, Syracuse, N Y *Prof of Zoology*, (1, 1949)
- Lindsay, Stuart, M D Univ of California Med School, Univ Hospital, San Francisco 22 *Pathologist* (4, 1949)
- Lindsley, Donald B, Ph D Northwestern Univ, Dept of Psychology, Evanston, Ill *Prof of Psychology* (1, 1937)
- Linegar, Charles R, Ph D E R Squibb and Sons, Research and Development Labs, New Brunswick, N J *Dir, Pharmacological Development Div*, (3, 1938)
- Lineweaver, Hans, Ph D U S Dept of Agriculture, Western Regional Research Lab, Albany 6, Calif *Head of Poultry Products Div* (2, 1941)
- Link, Karl Paul, Ph D Univ of Wisconsin, Biochemistry Bldg, Madison *Prof of Biochemistry* (2, 1931)
- Lintz, William, M D 36 Plaza St, Brooklyn, N Y *Late Prof of Immunology and Bacteriology and Clin Prof of Medicine, Long Island College of Medicine* (6, 1920)
- Lipman, Mrs Miriam O, A M Presbyterian Hospital, Dept of Medicine, 620 W 168th St, New York City *Research Asst, Edward Daniels Faulkner Arthritis Clinic* (6, 1931)
- Lipmann, Fritz, M D, Ph D Massachusetts General Hospital, Biochemical Research Lab, Boston 14 *Head, Prof of Biological Chemistry, Harvard Med School* (2, 1941)
- Lippincott, Stuart W, M D Univ of Washington School of Medicine, Seattle *Chairman, Dept of Pathology* (4, 1947)
- Lipton, Morris A, Ph D, M D Univ of Chicago, 59th St and Ellis Ave, Chicago 37, Ill *Resident, Dept of Psychiatry* (2, 1946)
- Lisco, Hermann, M D Argonne Natl Lab, Chicago 80, Ill *Dir, Med Div, Asst Prof of Pathology, Univ of Chicago* (4, 1947)
- Litchfield, John T, Jr, M D American Cyanamid Co, 1937 W Main St, Stamford, Conn *Dir of Pharmacology* (3, 1940)
- Little, James Maxwell, Ph D Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N C *Prof of Pharmacology, Assoc Prof of Physiology* (1, 1942, 3, 1947)
- Livingston, Alfred E, Ph D Temple Univ School of Medicine, Philadelphia, Pa *Prof of Pharmacology* (1, 1917, 3, 1920)
- Livingston, Robert B, M D 333 Cedar St, New Haven, Conn *Insti, Lab of Physiology* (1, 1949)
- Lloyd, David P C, Ph D Rockefeller Inst for Med Research, 66th St and York Ave, New York City 21 *Assoc Member* (1, 1939)
- Locke, Arthur P, Ph D Zonite Products Corp, New Brunswick, N J *Chief Research Chemist* (6, 1926)
- Lodholz, Edward, M D Univ of Pennsylvania, Med Labs, Philadelphia *Prof Emeritus of Physiology, Grad School of Medicine* (1, 1913)
- Loeb, Leo, M D Washington Univ Med School, St Louis, Mo *Prof Emeritus of Pathology* (1R, 1907, 4, 1913)
- Loefer, John B, Ph D Foundation of Applied Research, P O Box 2296, San Antonio 6, Tex *Chief Biologist* (1, 1949)
- Loew, Earl R, Ph D Boston Univ School of Medicine, 80 E Concord St, Boston 18, Mass (1, 1940, 3, 1946)
- Loewe, W S, M D Univ of Utah School of Medicine, Dept of Pharmacology, Salt Lake City 1 (3, 1936)
- Logan, Milan A, Ph D Univ of Cincinnati College of Medicine, Eden and Bethesda, Cincinnati 19, Ohio *Prof of Biological Chemistry* (2, 1936)
- Long, C N H, D Sc, M D Yale Univ, 333 Cedar St, New Haven 11, Conn *Dean, School of Medicine and Sterling Prof of Physiological Chemistry* (1, 1935, 2, 1927)
- Long, Esmond R, M D 7th and Lombard Sts, Philadelphia, Pa *Dir, Henry Phipps Inst, Prof of Pathology, Univ of Pennsylvania* (4, 1930)
- Long, Perrin Hamilton, M D Johns Hopkins Univ, 615 N Wolfe St, Baltimore, Md *Prof of Preventive Medicine* (3, 1940)
- Longcope, Warfield T, M D Cornhill Farm, Lee, Mass (3R, 1921, 4, 1913, 6R, 1923)
- Longenecker, Herbert Eugene, Ph D Univ of Pittsburgh, Pittsburgh 13, Pa *Dean, Grad School, Prof of Biochemistry* (2, 1940, 5, 1945)
- Longwell, Bernard B, Ph D Univ of Colorado School of Medicine, 4200 East 9th Ave, Denver 7, Colo *Prof of Biochemistry* (2, 1946)
- Loomis, Ted A, Ph D, M D Univ of Washington School of Medicine, Seattle *Asst Prof of Pharmacology* (3, 1948)
- Looney, Joseph M, M D 75 Park St, West Roxbury, Mass *Dir of Labs, Veterans Admin Hospital, West Roxbury, Mass* (2, 1922)
- Loosli, Clayton Garr, M D Univ of Chicago, Chicago, Ill *Assoc Prof of Medicine* (4, 1940)
- Loosli, J K, Ph D Cornell Univ, Animal Nutrition Lab, Ithaca, N Y *Assoc Prof of Animal Nutrition and Assoc Animal Nutritionist in Exper Station* (5, 1944)
- Lorber, Victor, M D, Ph D Western Reserve Univ School of Medicine, Dept of Biochemistry, Cleveland, Ohio *Assoc Prof* (1, 1944)

- Lorente de N6, Rafael**, M D Rockefeller Inst for Med Research, 66th St and York Ave, New York City *Member* (1, 1937)
- Lorenz, Egon**, Ph D Natl Cancer Inst, Bethesda, Md *Biophysicist* (4, 1942)
- Loring, H S**, Ph D Stanford Univ, Stanford Univ, Calif *Prof of Biochemistry* (2, 1938)
- Lotspeich, William D**, M D Oxford Univ, Dept of Biochemistry, Oxford, England *Research Fellow in Biochemistry* (1, 1948)
- Louis, Lawrence H**, D Sc Univ Hospital, Dept of Internal Medicine, Ann Arbor, Mich *Asst Prof of Biological Chemistry, Univ of Michigan* (2, 1949)
- Loveless, Mary H**, M D New York Hospital, 525 E 68th St, New York City *Research Assoc, Cornell Med School, Physician to Out-Patients, New York Hospital* (6, 1941)
- Lowell, Francis C**, M D 65 East Newton St, Boston, Mass *Assoc Prof of Medicine, Boston Univ School of Medicine* (6, 1942)
- Lowenbach, Hans**, M D Duke Univ Med School, Durham, N C *Assoc Prof of Neuropsychiatry and Physiology* (1, 1946)
- Lowry, Oliver H**, M D, Ph D Washington Univ School of Medicine, 4580 Scott Ave, St Louis 10, Mo *Prof and Head of Dept of Pharmacology* (2, 1942)
- Lu, Go**, M D Stanford Univ School of Medicine, Dept of Pharmacology and Therapeutics, 2398 Sacramento St, San Francisco 15, Calif *Research Assoc and Sterling-Winthrop Fellow* (3, 1949)
- Lubinski, Herbert**, M D Jewish General Hospital, 3755 St Catherine Rd, Montreal, Quebec, Canada *Bacteriologist and Serologist* (6, 1941)
- Lucas, Colin C**, Ph D Univ of Toronto, Banting and Best Dept of Med Research, Toronto, Ontario, Canada *Professor* (2, 1946)
- Lucas, George H W**, Ph D Univ of Toronto, Toronto, Ontario, Canada *Prof of Pharmacology* (2, 1925, 3, 1928)
- Luck, James Murray**, Ph D Stanford Univ, Stanford Univ, Calif *Prof of Biochemistry* (2, 1925)
- Lucké, Balduin**, M D 141 Montgomery Ave, Bala-Cynwyd, Pa *Prof of Pathology, Univ of Pennsylvania Med School, Philadelphia* (4, 1924)
- Luckhardt, Arno Benedict**, Ph D, M D Univ of Chicago, Chicago, Ill *The Dr Wm Beaumont Distinguished Service Prof of Physiology* (1, 1911)
- Ludewig, Stephan**, Ph D Univ of Virginia School of Medicine, Charlottesville *Assoc Prof of Biochemistry* (2, 1941)
- Luduena, Froilan P**, Ph D, M D Sterling-Winthrop Research Inst, Rensselaer, N Y (3, 1941)
- Lukens, Francis D W**, M D Univ of Pennsylvania 809 Maloney Clinic, 36th and Spruce Sts, Philadelphia *Assoc Prof of Medicine, Dir of George S Cox Med Research Inst* (1, 1938)
- Lund, E J**, Ph D Univ of Texas, Dept of Zoology and Physiology, Austin *Prof of General Physiology* (1, 1930)
- Lundberg, Walter O**, Ph D Hormel Inst, Austin, Minn *Director, Prof of Agricultural Biochemistry, Univ of Minn* (2, 1949)
- Lundgren, Harold P**, Ph D U S Dept of Agriculture, Western Regional Research Lab, Albany 6, Calif *Sr Chemist* (2, 1942)
- Lundy, John Silas**, M D Mayo Foundation, Rochester, Minn *Chief of Section on Anesthesia* (3, 1935)
- Lurie, Max B**, M D Henry Phipps Inst, 7th and Lombard Sts, Philadelphia, Pa *Assoc Prof of Exper Pathology* (4, 1934, 6, 1930)
- Lutz, Brenton R**, Ph D Boston Univ, 675 Commonwealth Ave, Boston, Mass *Prof of Biology* (1, 1925)
- Luyet, Basile J**, Sc D St Louis Univ School of Medicine, St Louis, Mo *Prof of Biology* (1, 1936)
- Lyall, Harold W**, Ph D New York State Dept of Health, Div of Labs and Research, Albany *Asst Dir in charge of Antitoxin, Serum, and Vaccine Labs* (6, 1937)
- Lyman, Carl M**, Ph D A and M College of Texas, College Station *Prof of Biochemistry and Nutrition* (2, 1940)
- Lyman, John F**, Ph D Ohio State Univ, Townsend Hall, Columbus *Prof of Agricultural Chemistry* (2, 1920, 5, 1933)
- Maaske, Clarence A**, Ph D Univ of Colorado School of Medicine, 4200 E 9th Ave, Denver *Assoc Prof of Physiology and Pharmacology* (1, 1945)
- Macallum, A Bruce**, M D, Ph D Univ of Western Ontario, Med School, London, Ontario, Canada *Research Prof of Biochemistry* (2, 1914)
- MacArthur, Edith H**, Ph D Skidmore College, Saratoga Springs, N Y *Prof and Dir of Home Economics* (5, 1933)
- MacCardle, Ross C**, Ph D Natl Cancer Inst, Bethesda, Md *Principal Cytologist* (4, 1948)
- MacCorquodale, D W**, Ph D Abbott Labs, North Chicago, Ill *Head of Biochemical Research* (2, 1934)
- MacFadyen, Douglas A**, M D Presbyterian Hospital, 1753 W Congress St, Chicago 12, Ill *Chairman of Dept of Biochemistry* (2, 1942)
- Macht, David Israel**, M D Sinai Hospital, Baltimore, Md *Consultant Pharmacologist, Research Pharmacologist, Sinai Hospital Labs* (1R, 1916, 3, 1915)
- Macht, Martin B**, Ph D The Jewish Hospital, Cincinnati 29, Ohio (1, 1948)
- MacKay, Eaton M**, M D Scripps Metabolic Clinic, La Jolla, Calif (1, 1930)

- MacKay, Ian F S**, Ph D Univ College of the West Indies, Jamaica, British West Indies *Prof of Physiology* (1, 1949)
- Mackenzie, Cosmo G**, Sc D Cornell Univ Med College, Dept of Biochemistry, 1300 York Ave, New York City 21 *Assoc Prof* (1, 1946, 2, 1946, 5, 1942)
- MacLeod, Colin M**, M D New York Univ College of Medicine, 477 First Ave, New York City *Prof of Bacteriology* (6, 1937)
- MacLeod, Florence L**, Ph D Univ of Tennessee, Knoxville *Prof of Nutrition* (2, 1927, 5, 1933)
- MacLeod, Grace**, Ph D 106 Morningside Drive, New York City 27 *Prof Emeritus of Nutrition, Teachers College, Columbia Univ* (2, 1924, 5, 1933)
- MacLeod, John**, Ph D Cornell Univ Med College, 1300 York Ave, New York City *Asst Prof of Anatomy* (1, 1942)
- MacNabb, Andrew L**, V S, B V Sc Guelph, Ontario, Canada *Principal, Ontario Veterinary College* (6, 1941)
- MacNider, William deB**, M D, Sc D Univ of North Carolina, Chapel Hill *Kenan Research Prof of Pharmacology* (1, 1912, 2, 1912, 3, 1909, 4, prior to 1920)
- MacPherson, Catherine F C**, Ph D 236 Brock Ave N, Montreal West, Quebec, Canada (2, 1947)
- MacVicar, Robert**, Ph D Oklahoma A & M College, Stillwater *Assoc Prof of Agricultural Chemistry Research* (2, 1949)
- Madden, Sidney C**, M D Brookhaven Natl Lab, Upton, L I, N Y *Head, Div of Pathology, Pathologist-in-Chief, Brookhaven Natl Lab Hospital* (4, 1939)
- Maddock, Stephen**, M D Boston City Hospital, Boston, Mass *Dir of Surgical Research Lab, Asst Prof of Surgery, Tufts Med School* (4, 1931)
- Madsen, Louis L**, Ph D Utah State Agricultural College, Dept of Animal Husbandry, Logan *Nutritionist* (5, 1940)
- Magath, Thomas B**, Ph D, M D Mayo Clinic, Rochester, Minn *Head of Div of Clinical Labs, Prof of Clinical Pathology and Parasitology, Univ of Minn, Mayo Foundation* (1, 1928)
- Magill, Thomas P**, M D Long Island College of Medicine, Brooklyn, N Y *Prof of Bacteriology* (6, 1937)
- Magoun, Horace W**, Ph D Northwestern Univ Med School, 303 E Chicago Ave, Chicago, Ill *Prof of Microscopic Anatomy* (1, 1937)
- Mahon, Eleanor Conway**, Ph D Iron River, Mich (4, 1940)
- Main, Rolland J**, Ph D Eaton Labs, Inc, Eaton Ave, Norwich, N Y *Med Editor and Consultant in Physiology* (1, 1936)
- Maison, George L**, M S, M D Boston Univ Med School, 80 E Concord St, Boston 18, Mass *Prof and Head of Pharmacology Dept* (1, 1939, 3, 1948)
- Major, Randolph T**, Ph D Merck and Co, Inc, Rahway, N J *Vice Pres and Scientific Dir* (2, 1942)
- Malkiel, Saul**, Northwestern Univ Med School, Evanston, Ill *Asst Prof of Medicine, Dir of Allergy Research Lab* (6, 1948)
- Mallory, G Kenneth**, M D Mallory Inst of Pathology, Boston City Hospital, Boston, Mass *Professor* (4, 1940)
- Mallory, Tracy B**, M D Massachusetts General Hospital, Boston *Dir of Pathology and Bacteriology, Prof of Pathology, Harvard Med School* (4, 1937)
- Maloney, Arnold H**, Ph D, M D Howard Univ School of Medicine, Washington, D C *Prof and Head of Dept of Pharmacology* (3, 1932)
- Maltaner, Frank**, Ph D Scarsdale Manor, Scarsdale, N Y (6, 1920)
- Maluf, N S Rustum**, Ph D 101 W Chestnut St, Louisville 2, Ky (1, 1942)
- Man, Evelyn B**, Ph D Yale Univ School of Medicine, 333 Cedar St, New Haven, Conn *Asst Prof in Biochemistry Lab, Dept of Medicine* (2, 1936)
- Manery, Jeanne Forest**, Ph D Univ of Toronto Med School, Toronto, Ontario, Canada *Demonstrator in Biochemistry* (1, 1937)
- Mangun, George H**, Ph D Henry Ford Hospital, 15713 Heyden St, Detroit 23, Mich *Sr Assoc in Clinical Chemistry* (2, 1947)
- Mann, Frank C**, M A, M D Mayo Clinic, Box 256, Rochester, Minn *Prof of Exper Medicine, Mayo Foundation* (1, 1916, 3, 1923, 4, 1924)
- Manning, G W**, M D 20 Woodington Ave, Toronto, Ontario Canada *Med Officer in Charge, No 2 R C A F Research Unit* (1, 1944)
- Manville, Ira Albert**, M D, Ph D 811 N W 19th Ave, Portland 9, Ore (1, 1933)
- Manwaring, Wilfred H**, M D Stanford Univ, Stanford University, Calif *Prof Emeritus of Bacteriology and Exper Pathology* (4, prior to 1920, 6, 1917)
- Marbarger, John P**, Ph D Univ of Illinois Physical Environment Unit, 1853 W Polk St, Chicago 12 *Research Dir, Aeromedical and Physical Environment Lab, Assoc Prof of Physiology* (1, 1949)
- Marcus, Stanley**, Ph D Univ of Utah, Dept of Bacteriology, Salt Lake City *Assoc Prof* (6, 1948)
- Marine, David**, M A, M D 18 Baltimore Ave, Rehoboth, Del (1R, 1910, 4, 1913)
- Markee, Joseph E**, Ph D Duke Univ School of Medicine, Durham, N C *Prof of Anatomy* (1, 1945)

- Markowitz, J, M D**, Ph D Univ of Toronto School of Medicine, Toronto, Ontario, Canada *Research Assoc in Physiology* (1, 1929)
- Marmont, George H**, Ph D Univ of Chicago, Inst of Radiobiology and Biophysics, Chicago 37, Ill *Asst Prof of Physiology* (1, 1941)
- Marmorston, Jessie** 416 N Bedford Drive, Beverly Hills, Calif *Asst Prof of Medicine, Univ of Southern California Staff, County and Cedars of Lebanon Hospitals* (6, 1932)
- Marrazzi, Amedeo S**, M D Med Div, Army Chemical Center, Md *Chief, Toxicology Section* (1, 1949, 3, 1938)
- Marsh, David F**, Ph D West Virginia Univ, Dept of Pharmacology, Morgantown *Head and Assoc Prof of Pharmacology* (3, 1946)
- Marsh, Gordon**, Ph D State Univ of Iowa, Iowa City *Assoc Prof of Zoology* (1, 1944)
- Marsh, M Elizabeth**, Ph D Kilian Research Labs, 49 W 45th St, New York City *Asst Dir* (1, 1929, 5, 1933)
- Marshak, Alfred Gordon**, Ph D New York Univ College of Medicine, New York City *Research Assoc* (1, 1940)
- Marshall, Eli Kennerly, Jr**, Ph D, M D Johns Hopkins Med School, Baltimore, Md *Prof of Pharmacology and Exper Therapeutics* (1, 1915, 2, 1913, 3, 1915)
- Marshall, Louise Hanson**, Ph D Natl Insts of Health, Lab of Physical Biology, Bethesda, Md *Physiologist* (1, 1946)
- Marshall, Wade H**, Ph D Natl Insts of Health, Bethesda, Md *Research Fellow, Lab of Physical Biology* (1, 1937)
- Martin, Arthur W, Jr**, Ph D Univ of Washington, Physiology Hall, Seattle *Assoc Prof of Physiology* (1, 1944)
- Martin, Donald S**, M D Duke Univ Hospital, Durham, N C *Assoc in Medicine* (6, 1943)
- Martin, Foster N, Jr**, Ph D, M D Tulane Univ Med School, Dept of Pharmacology, P O Station 20, New Orleans, La *Asst Prof of Pharmacology* (3, 1947)
- Martin, Stephens J**, Ph D St Francis Hospital, Hartford, Conn (1, 1933)
- Marx, Walter**, Ph D Univ of Southern California School of Medicine, Dept of Biochemistry, Los Angeles 7, Calif *Asst Prof of Biochemistry* (2, 1949)
- Mason, Edward C**, M D, Ph D Univ of Oklahoma School of Medicine, Oklahoma City *Prof of Physiology* (1, 1935)
- Mason, Eleanor Dewey**, Ph D Women's Christian College, Dept of Physiology and Nutrition, Cathedral P O, Madras, India *Prof of Physiology and Nutrition* (1, 1946)
- Mason, Herman C**, 3322 W Polk St, Chicago, Ill *Consulting Bacteriologist and Immunologist* (6, 1948)
- Mason, Harold L**, Ph D Mayo Clinic, Rochester, Minn *Prof of Physiological Chemistry, Mayo Foundation, Univ of Minnesota* (2, 1941)
- Mason, Howard S**, Ph D Natl Insts of Health, Bethesda 14, Md *Cancer Inst Fellow* (2, 1949)
- Mason, Karl Ernest**, Ph D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Prof of Anatomy* (5, 1941)
- Mason, Morton F**, Ph D Parkland Hospital, Oak Lawn Ave, Dallas, Tex *Prof of Pathological Chemistry and Exper Medicine, Southwestern Med College* (2, 1938)
- Massengale, Oliver N**, Ph D Mead Johnson and Co, Research Lab, Evansville, Ind *Research Biochemist* (2, 1937)
- Masson, Georges M C**, Ph D Cleveland Clinic Foundation, Research Div, Cleveland, Ohio (1, 1944)
- Mathews, Albert P**, Ph D Marine Biological Lab, Woods Hole, Mass *Carnegie Prof Emeritus of Biochemistry, Univ of Cincinnati* (1R, 1898, 2, 1906)
- Mason, Gustave A**, Ph D Minneapolis Memorial Blood Bank, Inc, 1914 La Salle Ave, Minneapolis, Minn *Director* (6, 1946)
- Matthews, Samuel A**, Ph D Williams College, Williamstown, Mass *Prof of Biology* (1, 1948)
- Mattill, Henry A**, Ph D State Univ of Iowa, Iowa City *Prof and Head of Dept of Biochemistry* (1, 1913, 2, 1909, 5, 1933)
- Mattis, Paul A**, D Sc Atomic Energy Med Research Project, Western Reserve Univ, Cleveland, Ohio *Section Chief, Pharmacology* (3, 1946)
- Maurer, Frank W**, Ph D 301 Lake Ave, Newton Highlands 61, Mass (1, 1941)
- Mautz, Frederick R**, M D Western Reserve Univ School of Medicine, Cleveland 6, Ohio *Asst Prof of Surgery* (1, 1945)
- Maver, Mary E**, Ph D Natl Cancer Inst, Bethesda 14, Md *Sr Biochemist* (2, 1947)
- Mavor, James Watt**, Ph D 8 Gracewood Park, Cambridge, Mass (1, 1930)
- Maxfield, Mary E**, Ph D Woman's Med College of Pennsylvania, Dept of Pharmacology, Philadelphia *Assoc Prof* (1, 1947)
- Mayer, Manfred M**, Ph D 1739 Eutaw Place, Baltimore, Md *Assoc Prof of Bacteriology, Johns Hopkins Hospital, School of Hygiene* (6, 1946)
- Mayerson, Hymen S**, Ph D Tulane Univ School of Medicine, Station 20, New Orleans, La *Prof and Head of Dept of Physiology* (1, 1928)
- Maynard, L A**, Ph D Cornell Univ, Ithaca, N Y *Prof of Nutrition and Biochemistry, Dir of School of Nutrition* (2, 1930, 5, 1933)
- Mazur, Abraham**, Ph D City College of New York, 139th St and Convent Ave, New York City 31 *Asst Prof in Dept of Chemistry* (2, 1944)

- McCann, William S**, M D, D Sc Univ of Rochester School of Medicine, Rochester, N Y *The Charles A Dewey Prof of Medicine* (2, 1923, 5, 1933)
- McCarrell, Jane D** Hood College, Dept of Biology, Frederick, Md (1, 1942)
- McCarty, Maclyn, M D** 66th St and York Ave, New York City 21 Assoc, *Rockefeller Inst for Med Research* (6, 1947)
- McCawley, Elton Leeman**, Ph D Yale Med School, New Haven, Conn *Instr in Pharmacology* (3, 1944)
- McCay, Clive M**, Ph D Cornell Univ, Animal Nutrition Lab, Dairy Bldg, Ithaca, N Y *Prof of Nutrition* (2, 1929, 5, 1933)
- McChesney, Evan William**, Ph D Sterling-Winthrop Research Inst, Rensselaer, N Y *Member, Biological Div* (1, 1944)
- McClellan, Walter S**, M D Saratoga Spa, Saratoga Springs, N Y *Med Dir, Assoc Prof of Medicine, Albany Med College* (1, 1931)
- McClendon, J F**, Ph D Route 1, Box 383, Trooper Rd, Norristown, Pa *Research Prof of Physiology, Hahnemann Med College* (1, 1910, 2, 1914, 5, 1935)
- McClung, L S** Indiana Univ, Bloomington *Assoc Prof and Chairman of Dept of Bacteriology* (6, 1948)
- McCollum, Elmer Verner**, Ph D Johns Hopkins Univ, Baltimore 18, Md *Prof Emeritus of Biochemistry* (2, 1910, 5, 1933)
- McCollum, Ernestine Becker**, M A Johns Hopkins Univ School of Hygiene, Baltimore 5, Md *Asst Prof of Biochemistry* (5, 1938)
- McCouch, Grayson Prevost**, M D Univ of Pennsylvania School of Medicine, Philadelphia *Assoc Prof of Physiology* (1, 1925)
- McCouch, Margaret Sunwalt**, Ph D Rose Tree Rd, R F D 1, Media, Pa (1, 1934)
- McCoy, Richard H**, Ph D Univ of Pittsburgh, Pittsburgh, Pa *Assoc Research Prof of Chemistry* (5, 1948)
- McCrea, Forrest D**, Ph D Duke Univ School of Medicine, Durham, N C *Assoc Prof of Physiology and Pharmacology* (1, 1929, 3, 1937)
- McCrudden, Francis H**, M D 19 Stoneleigh Rd, West Newton 65, Mass, *Asst Med Dir, New England Mutual Life Insurance Co* (2, 1906)
- McCulloch, Warren Sturgis**, M A, M D Univ of Illinois College of Medicine, 912 S Wood St, Chicago *Assoc Prof of Psychiatry* (1, 1936)
- McCutcheon, Morton**, M D Univ of Pennsylvania Med School Philadelphia *Prof of Pathology* (4, 1925)
- McDonald, Francis Guy**, Ph D Mead Johnson and Co, Research Lab, 2404 Pennsylvania, Evansville, Ind *Biochemist* (2, 1936, 5, 1947)
- McDonald, Roger K**, M D Baltimore City Hospitals, Cardiovascular Diseases Section, Baltimore 24, Md *Sr Asst Surgeon, USPHS, Natl Heart Inst, Bethesda, Md* (1, 1949)
- McElroy, William Swindler**, M D Univ of Pittsburgh School of Medicine, Pittsburgh, Pa *Dean, Prof of Physiological Chemistry* (2, 1919)
- McElroy, L W** Ph D Univ of Alberta, Dept of Animal Science, Edmonton, Canada *Assoc Prof of Animal Husbandry* (5, 1944)
- McElroy, William D**, Ph D Johns Hopkins Univ, Dept of Biology, Baltimore, Md *Asst Prof of Biology* (1, 1945)
- McFarland, Ross A**, Ph D Harvard Univ School of Public Health, Boston, Mass *Assoc Prof of Industrial Hygiene* (1, 1943)
- McFarlane, William Douglas**, Ph D 496 Queen St, E, Toronto, Ontario, Canada *Dir of Research, Canadian Breweries, Ltd* (2, 1933)
- McGinty, Daniel A**, Ph D Parke, Davis and Co, Detroit, Mich *Research Physiologist* (1, 1925)
- McGugan, Hugh Alister**, Ph D, M D Univ of Illinois College of Medicine, 1853 W Polk St, Chicago *Prof Emeritus of Pharmacology* (1R, 1907, 2, 1906, 3R, 1913)
- McHargue, J S**, Ph D Univ of Kentucky, Dept of Chemistry, Kentucky Agricultural Experiment Station, Lexington *Member Emeritus* (2, 1927)
- McHenry, E W**, Ph D Univ of Toronto, School of Hygiene, Toronto, Ontario, Canada *Prof of Public Health Nutrition* (2, 1938, 5, 1935)
- McIntyre, A R**, Ph D, M D Univ of Nebraska College of Medicine, 42nd and Dewey Ave, Omaha *Prof of Physiology and Pharmacology* (1, 1933, 3, 1938)
- McKee, Albert P** R F D 7, Iowa City, Iowa (6, 1948)
- McKee, Clara M**, Squibb Inst for Med Research, New Brunswick, N J *Assoc in Microbiology* (6, 1941)
- McKee, Frank W**, M D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Instr in Pathology, James E Gleason Fellow* (4, 1947)
- McKee, Ralph Wendell**, Ph D Harvard Med School, 25 Shattuck St, Boston 15, Mass *Asst Prof of Biological Chemistry* (2, 1946)
- McKennis, Herbert, Jr**, Ph D Med College of Virginia, Richmond *Assoc Prof of Biochemistry* (2, 1948)
- McKibbin, John M**, Ph D Syracuse Univ College of Medicine, Syracuse, N Y *Assoc Prof of Biochemistry* (2, 1948)
- McLain, Paul L**, M D Univ of Pittsburgh Med School Pittsburgh, Pa *Assoc Prof of Physiology and Pharmacology* (1, 1948, 3, 1940)
- McLean, Franklin C**, Ph D, M D Univ of Chicago, Chicago 37, Ill *Prof of Pathological Physiology* (1, 1914, 2, 1916, 3, 1916)

- McLean, I William, Jr, M D Parke, Davis Lab, Virus Research Div, Detroit, Mich *Research Virologist* (6, 1946)
- McLester, James S, M D Univ of Alabama, 930 S 20th St, Birmingham *Prof of Medicine* (5, 1933)
- McLimans, William F, Ph D Univ of Minnesota, 1834 Chelton Ave, St Paul *Asst Prof of Bacteriology and Immunology* (6, 1949)
- McManus, J F A, M D Med College of Alabama, Birmingham *Assoc Prof of Pathology* (4, 1948)
- McMaster, Philip D, M D Rockefeller Inst for Med Research, 66th St and York Ave, New York City (4, 1924)
- McMeekin, Thomas L, Ph D U S Dept of Agriculture, Eastern Regional Research Lab, Philadelphia, Pa *Head of Protein Div* (2, 1935)
- McNamara, Bernard P, Ph D Med Div, Army Chemical Center, Md *Pharmacologist* (3, 1947)
- McNaught, James Bernard, M D Univ of Colorado School of Medicine, Denver 7 *Prof and Head of Dept of Pathology* (4, 1936)
- McPhail, Murchie K, Ph D Natl Defense Board, Suffield Exper Station, Suffield, Alberta, Canada (3, 1941)
- McQuarrie, Irvine, Ph D, M D Univ of Minnesota, Minneapolis *Prof and Head of Dept of Pediatrics* (1, 1949, 4, 1927, 5, 1933)
- McShan, W H, Ph D Univ of Wisconsin, Biology Bldg, Madison 6 *Assoc Prof of Zoology* (2, 1947)
- Medes, Grace, Ph D Lankenau Hospital Research Inst, Philadelphia, Pa *Research Physiological Chemist* (2, 1930)
- Medlar, Edgar M, M D Veterans Admin Hosp, Sunmount, N Y *Chief Lab Pathologist* (4, 1927)
- Meek, Walter J, Ph D Univ of Wisconsin, Madison *Prof of Physiology, Assoc Dean of Med School* (1, 1908)
- Mehl, John W, Ph D Univ of Southern California, Dept of Biochemistry, 3551 Univ Ave, Los Angeles *Prof of Biochemistry* (2, 1946)
- Meier, Rolf, M D Basle Univ, Pelikanweg 7, Basle, Switzerland *Prof of Pathological Physiology* (3, 1949)
- Meiklejohn, Gordon, M D 678 Woodmont Ave, Berkeley, Calif *Instr in Medicine, Univ of California Med School* (6, 1948)
- Meites, Joseph Michigan State College, Dept of Physiology and Pharmacology, East Lansing *Asst Prof* (1, 1949)
- Mellon, Ralph R, M S, M D, D P H Western Pennsylvania Hospital, Inst of Pathology, Pittsburgh *Director* (6, 1918)
- Melnick, Daniel, Ph D The Best Foods, Inc, Research Labs, Bayonne, N J *Chief Technologist* (2, 1940, 5, 1942)
- Melnick, Joseph L, Ph D Yale Univ School of Medicine, 333 Cedar St, New Haven 11, Conn *Assoc Prof of Microbiology* (2, 1946, 6, 1948)
- Melville, Donald B, Ph D Cornell Univ Med College, 1300 York Ave, New York City 21 *Assoc Prof of Biochemistry* (2, 1947)
- Melville, Kenneth Ivan, M D McGill Univ, Montreal, Quebec, Canada *Asst Prof of Pharmacology* (3, 1931)
- Mendel, Bruno, M D Univ of Toronto, Banting and Best Dept of Med Research, 100 College St, Toronto 5, Ontario, Canada *Prof of Cellular Physiology* (2, 1947)
- Mendelson, E S, B A R F D 2, Telford, Pa *Physiologist, Head of Human Engineering Div, Naval Air Exper Station, Philadelphia, Pa* (1, 1949)
- Mendenhall, Walter L, M S, M D Milford, Iowa (1, 1915, 3, 1917)
- Mendez, Rafael, M D Natl Inst of Cardiology, Calzada de la Piedad 300, Mexico D F, Mexico *Head of Dept of Pharmacology* (3, 1944)
- Mendlowitz, Milton, M D 136 E 64th St, New York City 21 *Adjunct Physician in Mt Sinai Hospital of New York* (1, 1949)
- Meneely, George R, M D Thayer Veterans Admin Hospital, Nashville, Tenn *Asst Prof of Medicine* (4, 1946)
- Menkin, Valy, M A, M D Temple Univ School of Medicine, Philadelphia, Pa *Assoc Prof of Exper Pathology* (1, 1932, 4, 1932, 6, 1931)
- Menten, Maud L, M D, Ph D Univ of Pittsburgh, Pittsburgh, Pa *Prof of Pathology* (1, 1915, 4, 1927)
- Mettier, Stacy R, M D Univ of California Hospital, San Francisco *Prof of Medicine* (4, 1932)
- Mettler, Fred A, Ph D M D Columbia Univ College of Physicians and Surgeons, Dept of Neurology, New York City *Assoc Prof of Anatomy* (1, 1937)
- Meyer, Arthur E, Ph D Fellows Pharmaceutical Lab, New York City (1, 1948)
- Meyer, Curtis E, Ph D Upjohn Co, Kalamazoo, Mich *Sr Research Chemist* (2, 1942)
- Meyer, Frieda L, Ph D U S Dept of Agriculture, Bureau of Human Nutrition, Food and Nutrition Div, Washington 25, D C *Nutrition Specialist* (5, 1949)
- Meyer, Karl, M D, Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Assoc Prof of Biochemistry, Dept of Medicine* (2, 1934)
- Meyer, Karl F, M D, Ph D George W Hooper Foundation, Univ of California Med Center, San Francisco *Director* (4, 1930, 6, 1922)
- Meyer, Roland K, Ph D Univ of Wisconsin, Dept of Zoology, Biology Bldg, Madison 6 *Prof of Zoology* (1, 1949)

- Meyerhof, Otto, M D Univ of Pennsylvania School of Medicine, Dept of Physiological Chemistry, Philadelphia *Research Prof of Biochemistry* (2, 1941)
- Michel, Harry O, Ph D Med Div, Biochemical Section, Army Chemical Center, Md *Biochemist* (2, 1949)
- Mickelsen, Olaf, Ph D Nutrition Branch USPHS, Washington 25, D C *Chief Chemist* (2, 1941)
- Mider, George Burroughs, M D Strong Memorial Hospital, Rochester 7 N Y *Prof of Cancer Research* (4, 1940)
- Miles, Walter R, Ph D Yale Univ, 333 Cedar St, New Haven, Conn *Prof of Psychology, School of Medicine and Inst of Human Relations* (1, 1919)
- Milhorat, Ade T, M D Cornell Univ Med College, New York City 21 *Assoc Prof of Medicine and Instr in Pharmacology, Research Fellow, Russell Sage Inst of Pathology* (1, 1934, 3, 1937, 5, 1935)
- Miller, Augustus Taylor, Jr, Ph D Univ of North Carolina Med School, Chapel Hill *Assoc Prof of Physiology* (1, 1944)
- Miller, Benjamin F, M D 71 Mt Vernon St, Boston 8, Mass *Assoc Physician, Massachusetts General Hospital, Clin Prof of Medicine (on leave), George Washington Med School* (2, 1938)
- Miller, Carey D, M S Univ of Hawaii, Honolulu *Prof of Food and Nutrition, Hawaii Agricultural Exper Station* (5, 1942)
- Miller, C Phillip, M S, M D Univ of Chicago, Chicago, Ill *Prof of Medicine* (4, 1925, 6, 1928)
- Miller, Edgar G, Jr, Ph D Columbia Univ, 630 W 168th St, New York City *Prof of Biological Chemistry* (2, 1930)
- Miller, Franklin R, M D Jefferson Med College and Hospital, Div of Hematology, Philadelphia, Pa *Assoc Prof of Medicine* (4, 1940)
- Miller, Frederick R, M A, M D Univ of Western Ontario, Faculty of Medicine London, Ontario, Canada *Research Prof of Neurophysiology* (1, 1908)
- Miller, Gail L, Ph D Inst for Cancer Research, Dept of General Biochemistry, Hasbrook and Hartel Aves, Philadelphia 11, Pa *Assoc Member* (2, 1949)
- Miller, G H, M D American College of Surgeons, 40 E Erie St, Chicago 11, Ill *Dir of Educational Activities* (3, 1925)
- Miller, George A, Ph D Harvard Univ, Psycho-Acoustic Lab, Cambridge, Mass *Research Fellow* (1, 1948)
- Miller, H R, M D Montefiore Hospital, 1020 Park Ave, New York City (1, 1947)
- Miller, James A, Ph D Univ of Wisconsin Med School, McArdle Mem Laboratory Research, Madison 6 *Assoc Prof of Oncology* (2, 1949)
- Miller, Leon L, Ph D, M D Univ of Rochester School of Medicine and Dentistry, P O Box 287, Crittenden Station, Rochester, N Y *Assoc Prof of Radiation Biology and Biochemistry* (2, 1947)
- Miller, Lila, Ph D Univ of Michigan, Dept of Biological Chemistry, Ann Arbor *Asst Prof of Biological Chemistry* (2, 1946)
- Miller, Lloyd C, Ph D Sterling-Winthrop Research Inst, 33 Riverside Ave, Rensselaer, N Y *Dir of Biology Div* (3, 1938)
- Miller, R C, Ph D Pennsylvania State College, State College *Asst Prof Agricultural and Biological Chemistry* (5, 1935)
- Miller, Zelma Baker, Ph D 71 Mt Vernon Boston, Mass (2, 1940)
- Mills, Clarence A, Ph D, M D Cincinnati General Hospital, Cincinnati 29, Ohio *Prof of Exper Medicine, Univ of Cincinnati* (1, 1921, 2, 1921)
- Minot, Annie Stone, Ph D Vanderbilt Univ Med School, Nashville, Tenn *Assoc Prof of Biochemistry* (1, 1923)
- Mirsky, Alfred E, Ph D Rockefeller Inst for Med Research, 66th St and York Ave, New York City 21 *Member* (2, 1941)
- Mirsky, I Arthur, M D The Jewish Hospital, Cincinnati, Ohio *Dir, May Inst for Med Research, Asst Prof of Biochemistry, Univ of Cincinnati* (1, 1936)
- Mitchell, Harold H, M D 120 Lasky Drive, Beverly Hills, Calif (6, 1943)
- Mitchell, Harold H, Ph D Univ of Illinois, 555 Davenport Hall, Urbana *Prof of Animal Nutrition* (2, 1919, 5, 1933)
- Mitchell, Helen S, Ph D Univ of Massachusetts, Amherst *Dean of School of Home Economics* (2, 1925, 5, 1933)
- Mitchell, Philip H, Ph D Brown Univ, Providence 12, R I *Robert P Brown Prof of Biology* (2, 1909)
- Modell, Walter, M D Cornell Univ Med College, 1300 York Ave, New York City *Instr in Pharmacology* (3, 1944)
- Moe, Gordon Kenneth, Ph D, M D Univ of Michigan, Ann Arbor *Assoc Prof of Pharmacology* (3, 1944)
- Mohn, James F, M D 24 High St, Buffalo, N Y *Asst Prof in Bacteriology and Immunology, Univ of Buffalo School of Medicine* (6, 1946)
- Molitor, Hans, M D Merck Inst for Therapeutic Research, Rahway, N J *Director* (1, 1933, 3, 1942)
- Molland, Jacob, M D, Ph D Univ of Oslo, Oslo, Norway *Prof of Pharmacology* (3, 1948)
- Molnar, George W, Ph D Med Dept, Field Research Lab, Fort Knox, Kv *Physiologist* (1, 1949)

- Molomut, Norman**, Ph D Biological Labs, 16 Clinton St, Brooklyn 2, N Y *Dir of research and of Labs* (6, 1942)
- Moon, Virgil H**, M Sc, M D Wake Forest College, Bowman Gray School of Medicine, Winston Salem, N C *Visiting Prof of Pathology* (4, 1934)
- Moore, Arthur R**, Ph D Univ of Portland, Dept of Biology, Portland, Ore (1, 1912)
- Moore, Carl Vernon**, M D Washington Univ School of Medicine, St Louis, Mo *Prof of Medicine* (4, 1938, 5, 1941)
- Moore, Dan H**, Ph D U S Navy No 100, c/o Fleet Post Office, New York City (1, 1948)
- Moore, Lane A**, Ph D U S Dept of Agriculture, Div of Nutrition and Physiology, Bureau of Dairy Industry, Beltsville, Md *Head, Section of Dairy Cattle Nutrition* (5, 1940)
- Moore, Robert A**, M D Washington Univ Med School, St Louis, Mo *Dean and Prof of Pathology* (4, 1929)
- Moore, Robert M**, M D Univ of Texas Med School, Galveston (1, 1932)
- Moore, Stanford**, Ph D Rockefeller Inst for Med Research, York Ave at 66th St, New York City 21 *Associate* (2, 1949)
- Moorhouse, Victor Henry K**, M B Univ of Manitoba, Winnipeg, Manitoba, Canada *Prof of Physiology* (1, 1912)
- More, Robert H**, M D Pathological Inst, 3775 University St, Montreal, Quebec, Canada *Assoc Prof of Pathology, McGill Univ* (4, 1949)
- Morehouse, Laurence E**, Ph D Univ of Southern California, Los Angeles 7 *Assoc Prof* (1, 1947)
- Morgan, Agnes Fay**, Ph D Univ of California, Berkeley 4 *Prof of Home Economics, Biochemist, Agric Exper Station* (2, 1929, 5, 1933)
- Morgan, Charles F**, Ph D Georgetown Univ School of Medicine, Washington, D C *Prof and Chairman of Dept of Physiology* (1, 1948, 3, 1947)
- Morgan, Clifford T**, Ph D Johns Hopkins Univ, Psychology Dept, Baltimore 18, Md (1, 1943)
- Morgulis, Sergius**, Ph D Univ of Nebraska College of Medicine, Omaha 5 *Prof and Chairman of Dept of Biochemistry* (1, 1914, 2, 1916)
- Morison, Robert S**, M D Rockefeller Foundation, 66th St and York Ave, New York City 21 *Asst Dir of Med Sciences* (1, 1938)
- Moritz, Alan R**, M D Western Reserve Univ, Cleveland, Ohio *Prof of Pathology and Dir of the Institute* (4, 1934)
- Morrell, Clarence Allison**, Ph D Lab of Hygiene, Dept of Pensions and Natl Health, Sussex and John Sts, Ottawa, Ontario, Canada *Sr Pharmacologist* (3, 1937)
- Morris, Harold P**, Ph D Natl Cancer Inst, Bethesda 14, Md *Principal Biochemist in Nutrition* (2, 1944, 5, 1943)
- Morris, Marion C**, Ph D Public Health Research Inst of City of New York, Foot of East 15th St, New York City *Assoc in Div of Infectious Diseases* (6, 1936)
- Morrison, Dempsey B**, Ph D Univ of Tennessee College of Medicine, Memphis *Assoc Prof of Chemistry* (2, 1936)
- Morrison, James L**, Ph D Emory Univ School of Medicine, Emory University, Ga *Assoc Prof of Pharmacology* (3, 1944)
- Morse, Minerva** Ph D 5525 Kimbark Ave, Chicago, Ill *Research Assoc, Dept of Pediatrics, Univ of Chicago* (2, 1934)
- Morse, Withrow**, Ph D 32 Manchester Rd, Eastchester, via Tuckahoe, N Y *Consultant* (2, 1914)
- Mortimer, Bernard**, Ph D, M D 25 N Ottawa St, Joliet, Ill, Cook County Hospital, Chicago (1, 1936)
- Morton, John J**, M D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Prof of Surgery* (4, 1927)
- Moses, Campbell**, M D, Univ of Pittsburgh School of Medicine, Pittsburgh, Pa *Dir of Addison H Gibson Lab of Applied Physiology* (1, 1948)
- Motley, Hurley L**, Ph D, M D Jefferson Hospital, Philadelphia, Pa *Dir, Cardio-Respiratory Lab, Jefferson Med College and Assoc Prof of Medicine* (1, 1947)
- Mountain, Isabel M** Ph D 9 Coolidge Ave, White Plains, N Y (6, 1947)
- Mountcastle, Vernon B**, M D Johns Hopkins Univ Med School, Dept of Physiology, 710 N Washington St, Baltimore 5, Md *Asst Prof of Physiology* (1, 1949)
- Moxon, Alvin L**, Ph D College Station, Brookings, S D *Head, Chemistry Dept, South Dakota Agricultural Exper Station* (2, 1944)
- Moyer, Arden W**, Ph D 407 Mountain View Rd, Englewood, N J *Research Biochemist, Lederle Labs, Pearl River, N Y* (6, 1946)
- Moyer, Carl A**, Ph D 6417 Glenrose Ct, Dallas 1, Tex *Prof of Exper Surgery, Southwestern Med College* (1, 1943)
- Mudd, Stuart, M A**, M D Univ of Pennsylvania, Philadelphia *Prof of Bacteriology* (1, 1921, 4, 1927, 6, 1927)
- Muehlberger, Clarence W**, Ph D State Health Dept Labs Lansing, Mich *State Toxicologist* (3, 1928)
- Mueller, J Howard**, Ph D Harvard Med School, Boston, Mass *Charles Wilder Prof of Bacteriology and Immunology* (2, 1922, 4, 1927, 6, 1920)
- Mukherji, B**, D Sc All-India Inst of Hygiene and Public Health, Calcutta *Dir of Biochemical Standardization Lab* (3, 1938)
- Mulder, Arthur G**, Ph D Loyola Med School, 706 S Walcott St, Chicago, Ill (1, 1937)

- Mulford, Dwight J , Ph D 306 Riverway, Boston, Mass *Chief of Lab , Massachusetts Dept of Public Health, Assoc in Physical Chemistry, Harvard Univ* (2, 1948)
- Mulinos, M G , M D , Ph D New York Med College, Flower and Fifth Ave Hospitals, Fifth Ave and 105th St , New York City 29 *Assoc Prof of Pharmacology* (3, 1931)
- Mull, James W , Ph D 2020 State St , Quincy, Ill *Assoc , Quincy Specialties Co* (2, 1937)
- Müller, Otto H , R N Dr Syracuse Univ College of Medicine, Dept of Physiology, Syracuse 10, N Y (1, 1947)
- Mulligan, Richard M , M D Univ of Colorado School of Medicine, 4200 East 9th Ave , Denver *Prof of Pathology* (4, 1947)
- Mullin, F J , Ph D Univ of Chicago, Physiology Dept , Chicago 37, Ill *Asst Prof of Physiology* (1, 1937)
- Munro, F L , Ph D Jefferson Med College, 1025 Walnut St , Philadelphia 7, Pa *Research Chemist* (2, 1948)
- Munro, Muriel Platt, Ph D Jefferson Med College, 1025 Walnut St , Philadelphia 7, Pa *Research Chemist* (2, 1948)
- Munsell, Hazel E , Ph D Massachusetts Inst of Technology, Nutrition Biochemistry Labs , Dept of Food Technology, Cambridge *Research Assoc* (5, 1933)
- Muntwyler, Edward, Ph D Long Island College of Medicine, 350 Henry St , Brooklyn 2, N Y *Prof of Biochemistry* (2, 1931)
- Muntz, John A , Ph D 3356 Euclid Heights Blvd , Cleveland Heights, Ohio *Asst Prof , Western Reserve Univ* (2, 1948)
- Murlin, John R , Ph D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Prof Emeritus of Physiology and Dir Emeritus of Dept of Vital Economics* (1R, 1906, 2, 1908, 5, 1933)
- Murphy, James B , M D Rockefeller Inst for Med Research, 66th St and York Ave , New York City *Member* (4, prior to 1920)
- Murphy, Quillian R , M D , Ph D Univ of Wisconsin Med School, Dept of Physiology, Madison 6 *Asst Prof* (1, 1949)
- Murray, Everitt G D , M A McGill Univ , Montreal, Quebec, Canada *Prof and Head of Dept of Bacteriology and Immunology, Bacteriologist-in-Chief to the Royal Victoria Children's Memorial and Alexandra Hospitals* (6, 1933)
- Mushett, Charles W , Ph D Merck Inst for Therapeutic Research, Rahway, N J *Head of Dept of Pathology* (4, 1948)
- Muus, Jytte, Mag Scient Mount Holyoke College, South Hadley, Mass *Assoc Prof* (2, 1946)
- Myers, Chester N , Ph D 34 Cedar Place, Yonkers 5, N Y *Chief, Div Chemotherapy, New York Skin and Cancer Hospital, Dir of Chemical and Clinical Research, H A Metz Labs , Inc* (2, 1922)
- Nachmansohn, David, M D Columbia Univ College of Physicians and Surgeons, Dept of Neurology, 630 W 168th St , New York City 32 *Research Assoc in Neurology* (1, 1940)
- Nadler, J Ernest, M D , Med D Sc 80-16 Lefferts Blvd , Kew Gardens 15, N Y (3, 1940)
- Nahum, Louis N , M D 1142 Chapel St , New Haven, Conn *Asst Prof of Physiology, Yale Univ* (1, 1934)
- Najjar, Victor A , M D Univ of Cambridge, Unit for Microbiology, Cambridge, England (2, 1946)
- Nash, Thomas P , Jr , Ph D 875 Monroe Ave , Memphis, Tenn *Prof of Chemistry, Univ of Tennessee College of Medicine, Dean of School of Biological Sciences* (2, 1923)
- Nasset, Edmund S , Ph D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Prof of Physiology* (1, 1932, 5, 1940)
- Nastuk, William L , Ph D Columbia Univ College of Physicians and Surgeons, Dept of Physiology, 630 W 168th St , New York City 32 *Instr in Physiology* (1, 1949)
- Nathanson, Ira T , M S, M D Massachusetts General Hospital, Boston *Asst in Surgery, Instr in Surgery, Harvard Med School* (1, 1943)
- Nathanson, Morris D , M D 6333 Wilshire Blvd , Los Angeles, Calif *Assoc Clin Prof of Medicine, Univ of Southern California School of Medicine* (3, 1940)
- Necheles, Heinrich, M D , Ph D Michael Reese Hospital, Chicago, Ill *Dir of Dept of Gastrointestinal Physiology, Professorial Lecturer in Physiology, Univ of Chicago* (1, 1929)
- Neill, James M , Ph D Cornell Univ Med College, 1300 York Ave , New York City *Prof. of Bacteriology and Immunology* (6, 1930)
- Neilson, Charles Hugh, Ph D , M D Humboldt Bldg , St Louis, Mo *Assoc Dean and Prof of Medicine, St Louis Univ Med School* (2, 1906)
- Nelson, Arthur A , M D , Ph D Food and Drug Admin Div of Pharmacology, Washington 25, D C *Med Officer (Pathology)* (4, 1942)
- Nelson, Carl Ferdinand, M D , Ph D Univ of Kansas, Dept of Biochemistry, Lawrence *Prof of Physiological Chemistry* (2, 1914)
- Nelson, Carl T , M A , M D Harkness Pav Presbyterian Hosp , 180 Ft Washington Ave , New York City 32 (6, 1943)
- Nelson, Erwin E , Ph D , M D Food and Drug Admin , Drug Div , Washington 25, D C *Chief, New Drug Section, Adjunct Clin Prof of Pharmacology, George Washington Univ School of Medicine* (3, 1924)
- Nelson, E M , Ph D Food and Drug Admin , Washington, 18, D C *Chief, Vitamin Div* (2, 1927, 5, 1933)

- Nelson, John B**, Ph.D Rockefeller Inst for Med Research, Princeton, N J *Assoc Member* (4, 1934)
- Nelson, John M**, Ph D Columbia Univ, New York City 27 *Prof Emeritus of Organic Chemistry* (2, 1923)
- Nelson, Norton**, Ph D New York Univ College of Medicine, 477 First Ave, New York City 16 *Assoc Prof of Industrial Medicine* (2, 1946)
- Nelson, P Mabel**, Ph D Iowa State College, Ames *Dean, Div of Home Economics* (5, 1934)
- Nelson, Tell, M A**, M D 1415 Kalakaua Ave, Honolulu 19, T H *Practicing Physician* (6, 1938)
- Nelson, Victor E**, M S 559 Putnam St, Eau Claire, Wis *Prof of Physiological Chemistry* (2, 1924)
- Nelson, Warren O**, Ph D Univ of Iowa School of Medicine, Dept of Anatomy, Iowa City *Prof of Anatomy* (1, 1937)
- Neter, Erwin**, M D Children's Hospital, 219 Bryant St, Buffalo, N Y *Attending Bacteriologist* (6, 1937)
- Nettleship, Anderson**, M D Univ of Arkansas School of Medicine, Little Rock *Prof and Head of Dept of Pathology* (4, 1942)
- Neuberg, Carl**, Ph D, M D Med, Chem D 536 W 113th St, New York City 25 *Research Prof, New York Univ* (2, 1944)
- Neuman, William F**, Ph D, Univ of Rochester School of Medicine and Dentistry, 20 Alpine St, Rochester 7, N Y *Asst Prof of Biochemistry and Pharmacology* (2, 1949)
- Neumann, Charles**, M D 525 E 68th St, New York City 21 *Resident Surgeon, New York Hospital, Instr in Surgery, New York Univ Post-Grad Med School* (1, 1944)
- Neurath, Hans**, Ph D Duke Univ School of Medicine, Durham, N C *Prof of Physical Biochemistry* (2, 1940, 6, 1944)
- Neuwelt, Frank**, M D 504 Broadway, Gary, Ind *Research Assoc, Dept of Gastrointestinal Research, Michael Reese Hospital* (1, 1940)
- Neuwirth, Isaac**, Ph D 209 E 23rd St, New York City 10 *Prof of Pharmacology, New York Univ College of Dentistry* (2, 1924, 3, 1931)
- Newman, Elliot V**, M D, Johns Hopkins Hospital, Baltimore, Md *Asst Prof of Medicine* (1, 1948)
- Newman, Henry W**, M D Stanford Med School, Clay and Webster Sts, San Francisco 15, Calif *Assoc Prof of Medicine* (3, 1949)
- Nice, Leonard B**, Ph D Chicago Med School, 710 S Wolcott Ave, Chicago, Ill *Prof of Physiology and Pharmacology* (1, 1921)
- Nicholas, John S**, Ph D Yale Univ, Osborn Zoological Lab, New Haven, Conn *Bronson Prof of Comparative Anatomy* (1, 1927)
- Nicholson, Hayden C**, M S, M D Natl Research Council, Div of Med Sciences, 2101 Constitution Ave, Washington 25, D C (1, 1932)
- Nickerson, John L**, Ph D Columbia Univ, 630 W 168th St, New York City 32 *Assoc Prof of Physiology* (1, 1945)
- Nickerson, Mark**, Ph D Univ of Utah School of Medicine, Salt Lake City *Asst Prof of Pharmacology* (3, 1947)
- Nicoll, Paul A**, Ph D Indiana Univ, Bloomington *Asst Prof of Physiology* (1, 1945)
- Niemann, Carl G**, Ph D California Inst of Technology, Pasadena 4 *Prof of Organic Chemistry* (2, 1940)
- Nigg, Clara**, Ph D E R Squibb and Sons, New Brunswick, N J *Head of Depts of Bacteriology and Virology, and of Microbiological Development* (6, 1929)
- Nims, Leslie F**, Ph D Brookhaven Natl Lab, Biology Dept, Upton, Long Island, N Y *Acting Head of Dept* (1, 1940)
- Noble, Robert Laing**, M D, Ph D Univ of Western Ontario, Dept of Med Research, London, Ontario, Canada (1, 1941)
- Nord, F F**, Ph D Fordham Univ, Dept of Organic Chemistry, New York City *Prof of Organic Chemistry and Enzymology* (2, 1940)
- Norris, Earl R**, Ph D Univ of Washington, Seattle *Prof of Biochemistry and Exec Officer* (2, 1938)
- Norris, L C**, Ph D Cornell Univ, Rice Hall, Ithaca, N Y *Prof of Nutrition* (2, 1939, 5, 1934)
- Northrop, J H**, Ph D Univ of California, Berkeley 4 *Member of Rockefeller Inst* (2, 1938)
- Northrup, David W**, Ph D West Virginia Univ Med School, Morgantown *Prof of Physiology* (1, 1936)
- Novy, F G**, M D, Sc D 721 Forest Ave, Ann Arbor, Mich *Dean Emeritus of Med School and Prof Emeritus of Bacteriology, Univ of Michigan* (2, 1906, 4R, prior to 1919)
- Nowinski, W W**, Ph D Univ of Texas School of Medicine, Galveston *Research Assoc* (1, 1948)
- Nungester, Walter James**, Ph D, M D Univ of Michigan, Dept of Bacteriology, Ann Arbor *Professor* (6, 1949)
- Oberst, Fred W**, Ph D U S School of Aviation Medicine, Randolph Air Force Base, Randolph Field, Tex *Pharmacologist-Biochemist* (2, 1936, 3, 1949)
- Ochoa, Severo**, M D New York Univ College of Medicine, 477 First Ave, New York City 16 *Prof of Pharmacology* (2, 1942)
- Ogden, Eric** Ohio State Univ College of Medicine, Dept of Physiology, Columbus 10 *Prof of Physiology* (1, 1941)

- O'Hare, James P**, M D 520 Commonwealth Ave, Boston, Mass *Physician, Peter Bent Brigham Hospital, Lecturer in Medicine, Harvard Med School* (4, 1927)
- Ohlson, Margaret A**, Ph D Michigan State College, Dept of Foods and Nutrition, East Lansing *Prof and Head of Dept of Foods and Nutrition* (5, 1945)
- Okey, Ruth**, Ph D Univ of California, 1583 Life Sciences Bldg, Berkeley 4 *Prof of Home Economics and Biochemist, State Exper Station* (2, 1922, 5, 1933)
- Olcott, Harold S**, Ph D U S Dept of Agriculture, Western Regional Research Lab, Albany 6, Calif *Head of Vegetable Processing Div* (2, 1935)
- Oldham, Helen**, Ph D Univ of Chicago, Chicago, Ill *Asst Prof, Dept of Home Economics* (5, 1946)
- Olitsky, Peter K**, M D Rockefeller Inst for Med Research, 66th St and York Ave, New York City *Member* (6, 1917)
- Oliver, Jean Redman**, M D Hoagland Lab, 335 Henry St, Brooklyn, N Y *Prof of Pathology, Long Island College of Medicine* (1, 1924, 4, 1924)
- Oliver, Wade W**, M D Rockefeller Foundation, New York City *Assoc Dir of Div of Med Sciences* (4, 1925)
- Olmsted, J M D**, Ph D Univ of California, Berkeley *Prof of Physiology* (1, 1920)
- Olsen, Norman S**, Ph D Washington Univ Med School, 4580 Scott Ave, St Louis 10, Mo *Asst Prof of Biological Chemistry* (1, 1948, 2, 1949)
- Olson, Byron J**, Ph D, M D National Insts of Health, Bethesda, Md *Surgeon, Div of Infectious Diseases* (6, 1948)
- Olson, Carl, Jr**, D V M, Ph D Univ of Nebraska, Lincoln *Chairman of Dept of Animal Pathology and Hygiene* (4, 1937)
- Opdyke, David F**, Ph D Western Reserve Univ Med School, Cleveland 6, Ohio *Assoc Prof of Physiology* (1, 1945)
- Opie, Eugene L**, M D, Sc D Rockefeller Inst for Med Research, 66th St and York Ave, New York City 21 *Member* (1R, 1906, 4, 1913, 6R, 1923)
- Oppenheimer, Enid Tribe** 124 E 61st St, New York City *Instr in Physiology, Columbia Univ* (1, 1932)
- Oppenheimer, Ernst**, M D Ciba Pharmaceutical Products, Inc, Lafayette Park, Summit, N J *Vice-Pres in charge of Med Research* (3, 1944)
- Oppenheimer, Morton Joseph**, Ed M, M D 3400 N Broad St, Philadelphia, Pa *Prof of Physiology, Temple Univ School of Medicine* (1, 1942)
- Orent-Keiles, Elsa**, D Sc U S Dept of Agriculture, Bureau of Human Nutrition and Home Economics, Beltsville, Md. *In charge of Nutrition Investigations, Asst Chief, Foods and Nutrition Div* (2, 1935, 5, 1935)
- Ort, John M**, Ph D 401 Codwise Ave, New Brunswick, N J *Dir of Research, Carroll Dunham Smith Pharmacal Co* (2, 1932)
- Orten, Aline Underhill**, Ph D Wayne Univ College of Medicine, Detroit 26, Mich *Research Assoc, Dept of Physiological Chemistry* (5, 1946)
- Orten, James M**, Ph D Wayne Univ College of Medicine, Detroit 26, Mich *Assoc Prof of Physiological Chemistry* (2, 1936, 5, 1937)
- Orth, O Sidney**, Ph D, M D Univ of Wisconsin, S M I, Madison *Prof of Pharmacology* (1, 1942, 3, 1944)
- Osborne, Stafford L**, Ph D Northwestern Univ Med School, 303 E Chicago Ave, Chicago, Ill *Prof of Physical Medicine* (1, 1941)
- Oser, Bernard L**, Ph D Food Research Labs, Inc, 48-14 33rd St, Long Island City 1, N Y *Director* (5, 1945)
- Osler, Abraham G**, Ph D Johns Hopkins Hospital, Monument and Wolfe Sts, Baltimore, Md *Dir of Serologic Lab* (6, 1949)
- Oster, Robert H**, Ph D Univ of Maryland Med School, Greene and Lombard Sts, Baltimore *Asst Prof of Physiology* (1, 1938)
- Osterberg, Arnold E**, Ph D Abbott Labs, Med Dept, N Chicago, Ill *Assoc in Med Dept* (2, 1933)
- Osterhout, Marian I** Rockefeller Inst for Med Research, 66th St and York Ave, New York City 21 *Assoc, Div of General Physiology* (1, 1927)
- Osterhout, W J V**, Ph D Rockefeller Inst for Med Research, 66th St and York Ave, New York City 21 *Member Emeritus* (1, 1910)
- Otis, Arthur B**, Ph D Univ of Rochester, Dept of Physiology, Rochester 7, N Y *Asst Prof of Physiology* (1, 1946)
- Ott, Walther H**, Ph D Merck Inst for Therapeutic Research, Rahway, N J *Head of Dept of Biological Control and Poultry Nutrition* (5, 1949)
- Overman, Richard R**, Ph D Univ of Tennessee College of Medicine, Division of Physiology, Memphis *Assoc Prof* (1, 1946)
- Owen, Seward E**, Ph D 418 S 20th Ave, Maywood, Ill (1, 1938)
- Pace, Donald M**, Ph D Univ of Nebraska College of Pharmacy, Dept of Physiology and Pharmacology, Lincoln *Assoc Prof of Physiology* (1, 1944)
- Pace, Nello**, Ph D Univ of California, Div of Physiology, Berkeley 4 *Asst Prof of Physiology* (1, 1947)
- Pack, George T**, M D 139 E 36th St, New York City 16 *Fellow in Cancer Research, Memorial Hospital* (1, 1924)

- Packchanian, Ardzoony**, Ph D Univ of Texas School of Medicine, Galveston *Assoc Prof of Bacteriology and Tropical Medicine, Dir of Lab of Microbiology* (6, 1943)
- Page, Edouard**, Ph D Laval Univ Med School, Dept of Biochemistry, Quebec, Canada (1, 1947)
- Page, Ernest W**, M D Univ of California Hospital, Dept of Obstetrics and Gynecology, San Francisco 22 *Asst Prof* (1, 1947)
- Page, Irvine H**, M D Cleveland Clinic Foundation, 2040 E 93rd St, Cleveland 6, Ohio *Dir of Research* (1, 1937, 2, 1932)
- Painter, Elizabeth E**, Ph D Univ of Illinois School of Medicine, 1853 W Polk St, Chicago *Asst Prof of Physiology* (1, 1941)
- Palmer, John W**, Ph D E R Squibb and Sons, Georges Rd, New Brunswick, N J *Head of Dept of Protein Fractionation* (6, 1949)
- P'An, S Y**, M D Columbia Univ College of Physicians and Surgeons, New York City (3, 1941)
- Pangborn, Mary C**, Ph D New Scotland Ave, Albany, N Y *Sr Biochemist, New York State Dept of Health, Div of Labs and Research* (2, 1941)
- Pappenheimer, A M, Jr**, Ph D New York Univ College of Medicine, 477 First Ave, New York City 16 *Assoc Prof of Microbiology* (2, 1941, 6, 1938)
- Pappenheimer, Alwin M**, M D 45 Holden St, Cambridge, Mass *Prof Emeritus of Pathology, Columbia Univ* (4, 1922)
- Pappenheimer, John R**, Ph D Harvard Med School, Boston, Mass *Assoc in Physiology* (1, 1946)
- Papper, E M**, M D Columbia Presbyterian Med Center, 630 W 168th St, New York City *Prof of Anesthesiology* (3, 1949)
- Park, Edwards A**, M D Johns Hopkins Hospital, Baltimore, Md *Prof Emeritus of Pediatrics, Johns Hopkins Univ* (4, 1923)
- Parker, Robert F**, M D Univ Hosps, 2065 Adelbert Rd, Cleveland, Ohio *Assoc Prof of Microbiology and Medicine* (4, 1942, 6, 1935)
- Parkins, William M**, Ph D Route 2, Chariton, Iowa (1, 1939)
- Parpart, Arthur K**, Ph D Princeton Univ, Guyot Hall, Princeton, N J *Prof of Physiology* (1, 1937)
- Parr, Leland W**, Ph D George Washington Univ School of Medicine, 1335 H St NW, Washington, D C *Prof of Bacteriology* (4, 1940)
- Parrack, Horace O**, Ph D Wright-Patterson Air Force Base Aero-Med Lab, Dayton, Ohio *Research Physiologist* (1, 1948)
- Parsons, Helen T**, M D, Ph D Univ of Wisconsin, Madison *Prof of Home Economics, in charge of Purnell Research in Nutrition* (2, 1929, 5, 1933)
- Parsons, Robert J**, M D Highland Alameda County Hospital, 2701 14th Ave, Oakland, Calif *Pathologist, Dir of Labs* (4, 1939)
- Paschkis, Karl E**, M D Jefferson Med College, 1025 Walnut St, Philadelphia 7, Pa *Asst Prof of Medicine and Assoc in Physiology, Chief of Endocrine Clinic, Jefferson Hospital* (1, 1942)
- Patt, Harvey M**, Ph D Argonne National Lab, Chicago, Ill *Physiologist* (1, 1948)
- Patterson, Thos L**, Ph D Wayne Univ College of Medicine, 1512 St Antoine St, Detroit, Mich *Prof of Oro-Physiology and Dir of Dental Research, Univ of Detroit College of Dentistry* (1, 1920)
- Patterson, Wilbur I**, Ph D Food and Drug Admin, Washington 25, D C *Chief, Organic Analytical Methods* (2, 1948)
- Patton, H D**, Ph D, M D Univ of Washington School of Medicine, Dept of Physiology and Biophysics, Seattle 5 *Asst Prof* (1, 1947)
- Paul, John R**, M A, M D Yale Univ Med School, 333 Cedar St, New Haven, Conn *Prof of Preventive Medicine* (4, 1927, 6, 1937)
- Pearce, John Musser**, M D 525 E 68th St, New York City 21 *Prof of Pathology, Cornell Univ Med College, Attending Pathologist, New York Hospital* (4, 1942)
- Pearce, Louise**, M D Rockefeller Inst for Med Research, Princeton, N J *Assoc Member in Pathology and Bacteriology* (3, 1915, 4, 1925)
- Pearcy, Frank**, Ph D, M D 2606 Oak Lawn Ave, Dallas, Tex (1, 1928)
- Pearlman, William H**, Ph D Jefferson Med College, 1025 Walnut St, Philadelphia 7, Pa *Assoc Prof, Biochemistry Dept* (2, 1946)
- Pearse, Herman E**, M D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Prof of Surgery* (4, 1932)
- Pearson, Harold E**, M D, M P H Univ of Southern California Med School, Los Angeles *Assoc Prof of Bacteriology, Med Microbiologist, Los Angeles County Hospital* (6, 1948)
- Pearson, P B**, Ph D Atomic Energy Commission, Div of Biology and Medicine, Washington 25, D C *Chief of Biology Branch* (2, 1944, 5, 1940)
- Pease, Marshall C, Jr**, M D Branchville Rd, R F D 4, Ridgefield, Conn *Historian of Am Acad of Pediatrics* (6, 1920)
- Peck, Robert L**, Ph D 939 Madison Ave, Plainfield, N J *Sr Chemist, Merck and Co, Inc* (2, 1947)
- Pemberton, Ralph**, M S, M D Univ of Pennsylvania, Philadelphia *Prof of Medicine, Graduate School of Medicine* (5, 1933)
- Penfield, Wilder G**, M D, D Sc McGill Univ, Montreal, Quebec, Canada *Prof of Neurology and Neurosurgery* (1, 1932)
- Pennington, Mary Engle**, Ph D 233 Broadway, New York City 7 *Consultant in Connection with*

- the Handling, Transportation and Storage of Perishables* (2, 1908)
- Penrod, Kenneth E**, Ph D Boston Univ School of Medicine, Dept of Physiology, 80 E Concord St, Boston, Mass *Asst Prof of Physiology* (1, 1946)
- Peoples, S Anderson**, M D Univ of California, Dept of Veterinary Science, Davis *Prof of Pharmacology* (3, 1937)
- Perlman, Ely**, M D 77-14 113th St, Forest Hills, L I, N Y (6, 1944)
- Perlzweig, William A**, Ph D Box 3711, Duke Univ School of Medicine, Durham, N C *Prof and Chairman of Dept of Biochemistry and Nutrition, Biochemist, Duke Hospital* (2, 1924, 5, 1944)
- Permar, Howard H**, M D Pathologic Labs, Mercy Hospital, Pittsburgh, Pa *Dir of Labs* (4, 1925)
- Petermann, Mary L**, Ph D Sloan-Kettering Inst for Cancer Research, 444 E 68th St, New York City 21 *Associate* (2, 1947)
- Peters, John P**, M D 123 Marvel Rd, New Haven 15, Conn *John Slade Ely Prof of Medicine, Yale Univ School of Medicine* (2, 1922)
- Peters, Lawrence**, Ph D Western Reserve Univ Med School, Dept of Pharmacology, 2109 Adelbert Rd, Cleveland 6, Ohio *Sr Instr in Pharmacology* (3, 1946)
- Petersen, William E**, Ph D Univ of Minnesota, Div of Dairy Husbandry, St Paul 1 *Professor* (1, 1947)
- Petersen, William F**, M D 1322 Astor St, Chicago, Ill *Prof of Pathology, Univ of Illinois* (3, 1923, 4R, 1923)
- Peterson, William H**, Ph D Univ of Wisconsin, Biochemistry Bldg, Madison *Prof of Biochemistry* (2, 1919, 5, 1936)
- Pett, L B**, M D, Ph D Dept of Natl Health and Welfare, Ottawa, Ontario, Canada *Dir of Nutrition* (2, 1937, 5, 1945)
- Pfeiffer, Carl C**, Ph D, M D Univ of Illinois, Dept of Pharmacology, 1853 W Polk St, Chicago 12 *Prof and Chairman of Dept of Pharmacology* (3, 1938)
- Pfiffner, Joseph J**, Ph D Parke, Davis & Co, Research Labs, Detroit 32, Mich *Research Chemist* (1, 1931, 2, 1931, 5, 1946)
- Phatak, Nilkanth M**, Ph D North Pacific College of Oregon, School of Dentistry, Portland *Assoc Prof of Physiology, Pharmacology, and Research, Instr, Dept of Pharmacology, Univ of Oregon Med School* (3, 1941)
- Philips, Frederick S**, Ph D Sloan-Kettering Inst for Cancer Research, 444 E 68th Street, New York City 21 *Chief, Pharmacology Dept* (3, 1947)
- Phillips, Paul H**, Ph D Univ of Wisconsin, Madison *Prof of Biochemistry* (2, 1940, 5, 1938)
- Phillips, Robert Allan**, M D U S Naval Med Research Unit No 3, American Embassy at Cairo, Egypt, %Navy Pouch Section, Navy Dept, Washington 25, D C (1, 1938)
- Pick, Ernst Peter**, M D 19 E 98th St, New York City *Assoc Pharmacologist, Mt Sinai Hospital, Clin Prof of Pharmacology, Columbia Univ* (3, 1940)
- Pierce, Harold B**, Ph D Univ of Vermont College of Medicine, Burlington *Prof and Chairman of Dept of Biochemistry* (2, 1929, 5, 1933)
- Pierce, Harold Fisher**, Ph D, M D State Veterans Hospital, Rocky Hill Conn (1, 1928)
- Pierce, Ira H**, Ph D Univ of Iowa, Iowa City *Assoc Prof of Pharmacology* (3, 1933)
- Pike, Frank H**, Ph D 437 W 59th St, New York City 19 *Assoc Prof of Physiology, Columbia Univ* (1, 1907)
- Pillemer, Louis**, Ph D Western Reserve Univ, Inst of Pathology, Cleveland, Ohio *Assoc Prof of Immunochemistry* (6, 1942)
- Pincus, Gregory**, Sc D Worcester Foundation for Exper Biology, 222 Maple Ave, Shrewsbury, Mass (1, 1935)
- Pincus, I J**, M D Jefferson Med College, Philadelphia, Pa *Assoc in Physiology* (1, 1948)
- Pinkerton, Henry**, M D St Louis Univ School of Medicine, St Louis, Mo *Prof of Pathology* (4, 1931)
- Pinkston, James O**, Ph D American Univ of Beirut, Beirut, Lebanon *Pharmacologist* (1, 1936, 3, 1939)
- Pinson, Ernest A**, Ph D 139 N Walnut St, Yellow Springs, Ohio (1, 1943)
- Pittman, Martha S**, Ph D Manhattan, Kan (5, 1933)
- Pitts, Robert F**, Ph D, M D Syracuse Univ College of Medicine, Syracuse, N Y *Prof of Physiology* (1, 1934)
- Pollack, Herbert**, Ph D, M D 45 E 66th St, New York City 21 *Assoc Physician and Chief of Metabolism Clinics, Mt Sinai Hospital* (1, 1933, 5, 1935)
- Pomerat, Charles Marc**, Ph D Univ of Texas Med School, Galveston *Prof of Anatomy* (1, 1944)
- Pommerenke, W T**, Ph D, M D Univ of Rochester School of Medicine and Dentistry, Rochester 7, N Y *Assoc Prof of Obstetrics and Gynecology* (1, 1947)
- Pond, Samuel E**, Ph D 400 S Main St, East Hartford, Conn *Consulting Engineer, P and W A Div, United Aircraft Corp* (1, 1924)
- Ponder, Eric**, M D, Sc D Nassau Hospital, Mineola, Long Island, N Y (1, 1931)
- Poppen, John R**, M D Aero Med Acceleration Lab, Naval Air Development Center, Johnsville, Pa *Director* (1, 1948)
- Popper, Hans**, Ph D, M D Cook County Hospital, 1825 W Harrison St, Chicago 12, Ill

- Dir of Dept of Pathology and Scientific Div of Hektoen Inst for Med Research, Assoc Prof of Pathology, Northwestern Univ Med School* (4, 1942)
- Porter, Eugene L**, Ph D Univ of Texas Med Branch, Galveston *Prof of Physiology* (1, 1913)
- Porter, Thelma**, Ph D Univ of Chicago, Chicago, Ill *Prof and Chairman of Dept of Home Economics* (5, 1944)
- Poth, Edgar J**, M D, Ph D Univ of Texas Med School, Galveston *Prof of Surgery* (1, 1946)
- Potter, Truman S**, M D 82 N Prospect St, Amherst, Mass *Independent Research Worker* (6, 1939)
- Potter, Van R**, Ph D Univ of Wisconsin Med School, McArdle Memorial Lab, Madison *Prof of Oncology* (2, 1941)
- Powell, Horace M**, Sc D 5565 Washington Blvd, Indianapolis, Ind *Head Bacteriologist, Eli Lilly & Co* (6, 1934)
- Power, Marschelle H**, Ph D Mayo Clinic, Rochester, Minn *Prof of Physiological Chemistry, Mayo Foundation, Univ of Minnesota* (2, 1932)
- Pratt, Joseph H**, M D, Sc D New England Med Center, 25 Bennet St, Boston, Mass *Physician-in-Chief, Boston Dispensary and Joseph H Pratt Diagnostic Clinic, Prof Emeritus of Clin Medicine, Tufts Med School* (1, 1910, 3, 1910, 4, 1927)
- Preisler, Paul W**, Ph D 4580 Scott Ave, St Louis 10, Mo *Asst Prof of Biochemistry, Washington Univ School of Medicine* (2, 1931)
- Pressman, David**, Ph D Sloan-Kettering Inst for Cancer Research, 444 East 68 St, New York City 21 *Sr Fellow in Cancer Research* (6, 1949)
- Price, Clifford W**, Ph D U S Food and Drug Admin, Washington, D C *Bacteriologist, Antibiotics Analyst, Div of Penicillin Control and Immunology* (6, 1946)
- Prinzmetal, Myron, M.A.**, M D 300 S Beverly Drive, Beverly Hills, Calif *Sr Attending Physician, Cedars of Lebanon Hospital, Los Angeles* (3, 1941)
- Prosser, C Ladd**, Ph D Univ of Illinois, Natural History Bldg, Urbana (1, 1935)
- Puestow, Charles B**, M D, Ph D Univ of Illinois College of Medicine, 1853 W Polk St, Chicago *Asst Prof of Surgery* (1, 1934)
- Pugsley, L I**, Ph D Dept of Natl Health and Welfare Food and Drug Lab, Ottawa, Ontario, Canada *Chief of Lab Service* (2, 1937)
- Putnam, Frank W**, Ph D Univ of Chicago, 947 E 58th St, Chicago 37, Ill *Asst Prof of Biochemistry* (2, 1947)
- Quackenbush, Forrest W**, Ph D R-2, Brookston, Ind *Prof and Head of Dept of Agricultural Chemistry, Purdue Univ* (2, 1946)
- Quaife, Mary L**, Ph D Distillation Products, Inc, 755 Ridge Rd W, Rochester 13, N Y *Sr Research Chemist, Dept of Biochemistry* (2, 1948)
- Quastel, J H**, D Sc, Ph D McGill Univ, Montreal, Quebec, Canada *Prof of Biochemistry* (2, 1948)
- Queen, Frank B**, M D Univ of Oregon School of Medicine, 3181 S W Marquam Hill Rd, Portland *Prof of Pathology* (4, 1941)
- Quick, Armand J**, M D, Ph D 561 N 15th St, Milwaukee 3, Wis *Prof and Dir of Dept of Biochemistry, Marquette Med School* (2, 1932, 3, 1937)
- Quigley, J P**, Ph D Univ of Tennessee, Dept of Pharmacology, Memphis 3 *Prof and Chief of Div of Pharmacology* (1, 1929, 3, 1945)
- Quinn, Edmond John**, Ph D 106 N Lee Ave, Rockville Center, Long Island, N Y *Medicinal Sales Div, Merck & Co, Inc, Rahway, N J* (2, 1927, 5, 1933)
- Raab, Wilhelm**, M D Univ of Vermont College of Medicine, Div of Exper Medicine, Burlington *Prof, Head of Division and of Cardiovascular Clin Research Unit* (1, 1949)
- Rabinowitch, I M**, D Sc, M D C M 1020 Med Arts Bldg, Sherbrooke and Guy Sts, Montreal, Quebec, Canada *Assoc Prof of Medicine and Lecturer in Med Jurisprudence and Toxicology, McGill Univ, Dir, Inst for Research, Montreal General Hospital* (2, 1928, 5, 1933)
- Rachele, Julian R**, Ph D Cornell Univ Med College, 1300 York Ave, New York City 21 *Assoc Prof of Biochemistry* (2, 1948)
- Rackemann, Francis M**, M D 263 Beacon St, Boston, Mass *Physician, Massachusetts General Hospital, Lecturer in Medicine, Harvard Med School* (6, 1923)
- Racker, Efraim**, M D New York Univ College of Medicine, New York City 16 *Asst Prof of Microbiology* (2, 1948)
- Raffel, Sidney**, Sc D, M D Stanford Univ, Dept of Bacteriology and Exper Pathology, Stanford Univ, Calif *Asst Prof* (6, 1938)
- Rahn, Hermann**, Ph D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Asst Prof of Physiology* (1, 1944)
- Rake, Geoffrey W**, M B Squibb Inst for Med Research, Div of Microbiology, New Brunswick, N J *Head of Div* (6, 1939)
- Rakestraw, Norris W**, Ph D Univ of California, Scripps Inst of Oceanography, LaJolla *Prof of Chemistry* (2, 1925)
- Rakieten, Nathan**, Ph D Bristol Labs, Inc, P O Box 657, Syracuse 2, N Y *Pharmacologist and Toxicologist* (1, 1941)
- Ralli, Elaine P**, M D 477 First Ave, New York City *Assoc Prof of Medicine, New York Univ College of Medicine* (1, 1934, 5, 1933)
- Ralston, H J**, Ph D College of Physicians and Surgeons, Dept of Physiology, 344 14th St,

- San Francisco 3, Calif *Assoc Prof of Physiology* (1, 1947)
- Rammelkamp, Charles H , Jr** , M D Western Reserve Univ , Dept of Preventive Medicine, Cleveland 6, Ohio *Assoc Prof of Medicine* (6, 1943)
- Ramsey, Robert Weberg**, Ph D Med College of Virginia, Richmond *Assoc Prof of Physiology and Pharmacology* (1, 1939)
- Randall, Lowell O** , Ph D Hoffmann-LaRoche, Inc , Nutley 10, N J *Pharmacologist* (2, 1939)
- Randall, Walter C** , Ph D St Louis Univ School of Medicine, 1402 S Grand Blvd , St Louis, Mo *Instr in Physiology* (1, 1943)
- Randall, William A** , Ph D Food and Drug Admin , Washington 25, D C *Bacteriologist, Div of Penicillin Control and Immunology* (6, 1946)
- Rane, Leo**, Ph D Lederle Labs , Inc , Pearl River, N Y *Dept Head, Normal Blood Plasma* (6, 1942)
- Rantz, Lowell A** , M D Stanford Univ Hospital, San Francisco 15, Calif *Asst Prof of Medicine* (3, 1946)
- Rapoport, Samuel**, M D , Ph D Children's Hospital Research Foundation, Elland and Bethesda, Cincinnati, Ohio *Assoc Prof of Pediatrics and Asst Prof of Biochemistry, Univ of Cincinnati* (2, 1941)
- Rapport, David**, M D 416 Huntington Ave , Boston, Mass *Prof of Physiology, Tufts College Med School* (1, 1922)
- Raska, Sigwin**, Ph D Univ of North Dakota, Dept of Physiology and Pharmacology, Grand Fork *Prof of Pharmacology* (1, 1947)
- Rasmussen, A F** , Ph D , M D Univ of Wisconsin Med School, Dept of Med Microbiology , Madison *Assoc Prof* (6, 1949)
- Rasmussen, Andrew Theodore**, Ph D Univ of Minnesota Med School, Minneapolis *Prof of Neurology* (1, 1919)
- Ratner, Bret**, M D 50 E 78th St , New York City *Prof of Pediatrics, New York Univ College of Medicine* (4, 1940, 6, 1928)
- Ratner, Sarah**, Ph D New York Univ College of Medicine, Dept of Pharmacology, 477 First Ave , New York City 16 *Asst Prof of Pharmacology* (2, 1944)
- Raulston, B O** , M D 200 S Hudson Ave , Los Angeles, Calif *Prof of Medicine and Dir of Clinical Teaching, Univ of Southern California School of Medicine* (3, 1942)
- Ravdin, I S** , M D Univ of Pennsylvania School of Medicine, Philadelphia *John Rhea Barton Prof of Surgery, Chief Surgeon, Hospital of the Univ of Pennsylvania* (1, 1930, 4, 1930)
- Rawson, Rulon W** , M D Memorial Hospital, New York City *Attending Physician, Chief, Dept of Clinical Investigation, Sloan-Kettering Inst* (1, 1947)
- Raymond, Albert L** , Ph D G D Searle and Co , P O Box 5110, Chicago 80, Ill *Vice Pres in charge of Research and Development* (2, 1932)
- Redfield, Alfred C** , Ph D Woods Hole, Mass *Prof of Physiology, Harvard Univ* (1, 1919)
- Reed, Carlos I** , Ph D Univ of Illinois College of Medicine, 1853 W Polk St , Chicago *Prof of Physiology* (1, 1923)
- Reed, Emerson A** , Ph D Hahnemann Med College, Philadelphia, Pa *Asst Prof of Physiology* (1, 1948)
- Reed, Howard S** , Ph D 3048 Life Sciences Bldg , Univ of California, Berkeley *Prof of Plant Physiology* (2, 1909)
- Reese, John D** , M D North Carolina Sanatorium, McCain *Pathologist and Lab Dir* (4, 1949)
- Rehm, Warren S , Jr** , Ph D , M D Univ of Louisville School of Medicine, Louisville, Ky *Prof of Physiology* (1, 1945)
- Reid, Marion Adelaide**, Ph D New Jersey College for Women, New Brunswick *Asst Prof , Dept of Zoology* (1, 1941)
- Reid, Mary E** , Ph D Natl Insts of Health, Bethesda 14, Md *Cytologist* (5, 1947)
- Reimann, Hobart A** , M D Jefferson Hospital, Philadelphia, Pa *Prof of Medicine, Jefferson Med College* (4, 1933)
- Reimann, Stanley P** , M D , Sc D 703 W Phil-Ellena St , Mount Airy, Philadelphia, Pa *Dir of Research Inst of Lankenau Hospital, Prof of Oncology, Hahnemann Med College and Hospital, Philadelphia* (1, 1921, 4, 1924)
- Reinecke, Roger M** , Ph D , M D Univ of Minnesota, Dept of Physiology, Minneapolis 14 *Asst Prof* (1, 1947)
- Reiner, John M** , Ph D Tufts College Med School, Dept of Physiology, Boston, Mass (1, 1947)
- Reiner, Laszlo**, M D , Ph D Wallace and Tiernan Products, Inc , 165 Franklin St , Bloomfield, N J *Dir , Pharmaceutical Research* (2, 1942, 6, 1933)
- Reinhold, John G** , Ph D Univ of Pennsylvania Hospital, 702 Maloney Bldg , Philadelphia, Pa *Asst Prof of Physiological Chemistry and Medicine* (2, 1936)
- Remington, John W** , Ph D Univ of Georgia School of Medicine, Augusta *Asst Prof of Physiology* (1, 1943)
- Remington, Roe E** , Ph D , P O Box 1252, Hendersonville, N C *Consultant* (2, 1930, 5R, 1934)
- Renfrew, Alice G** , Ph D Mellon Inst of Industrial Research, Univ of Pittsburgh, Pittsburgh, Pa *Sr Fellow* (2, 1939)
- Reynolds, Chapman**, M D Louisiana State Univ School of Medicine, New Orleans *Asst Prof of Pharmacology* (3, 1937)

- Reynolds, Orr E**, Ph D Office of Naval Research, Med Sciences Div, Washington, D C *Head of Physiology Branch* (1, 1948)
- Reynolds, Samuel R M**, Ph D 4028 Deepwood Rd, Baltimore 18, Md *Staff Member and Physiologist, Carnegie Inst of Washington, Dept of Embryology* (1, 1932)
- Reznikoff, Paul**, M D New York Hospital, 525 E 68th St New York City *Assoc Prof of Clin Medicine, Cornell Univ Med College* (1, 1927)
- Rhoads, Cornelius Packard**, M D Memorial Hospital, 444 E 68th St, New York City *Dir, Prof of Pathology, Cornell Univ Med College* (4, 1930)
- Rhoads, Jonathan Evans**, M D, D Sc 4023 Pine St, Philadelphia 4, Pa *Asst Prof of Surgical Research* (1, 1946)
- Rice, Christine E**, Ph D Animal Diseases Research Inst, Canadian Dept of Agriculture, Hull, Quebec, Canada *Agricultural Scientist* (6, 1938)
- Rice, Harold V**, Ph D Univ of Alberta, Edmonton, Alberta, Canada *Prof of Physiology* (1, 1948)
- Rice, James C**, Ph D Univ of Mississippi, P O Box 475, University *Prof of Pharmacology* (3, 1941)
- Rich, Arnold Rice**, M D Johns Hopkins Hospital, Baltimore, Md *Baxley Prof of Pathology, Johns Hopkins Univ* (4, 1924)
- Richards, Alfred N**, Ph D, M D, Univ of Pennsylvania School of Medicine, Philadelphia 4 *Prof Emeritus of Pharmacology* (1R, 1900, 2, 1906, 3R, 1909)
- Richards, Oscar W**, Ph D American Optical Co, Scientific Instrument Div, Box A, Buffalo 15, N Y *Chief Biologist* (1, 1934)
- Richards, Richard Kohn**, M D Abbott Labs, North Chicago, Ill *Dir of Pharmacologic Research, Lecturer in Pharmacology, Northwestern Univ Med School* (1, 1938, 3, 1947)
- Richardson, Arthur P**, M D Emory Univ School of Medicine, Dept of Pharmacology, Emory University, Ga *Prof of Pharmacology* (3, 1939)
- Richardson, Luther R**, Ph D P O Box 102, College Station, Tex (5, 1942)
- Richter, Curt P**, Ph D Phipps Psychiatric Clinic, Johns Hopkins Hospital, Baltimore, Md *Assoc Prof of Psycho-biology, Johns Hopkins Univ* (1, 1924)
- Richter, Maurice N**, M D 303 E 20th St, New York City *Prof of Pathology, Bellevue Med Center, Post-Grad Med School Director, Univ Hosp* (4, 1931)
- Ricketts, Henry T**, M D Univ of Chicago, Dept of Medicine, Chicago, Ill *Assoc Prof of Medicine* (1, 1940)
- Riegel, Byron**, Ph D Northwestern Univ, Dept of Chemistry, Evanston, Ill *Professor* (2, 1942)
- Riegel, Cecilia**, Ph D Univ of Pennsylvania Hospital, Philadelphia 4, Pa *Assoc, Dept of Research Surgery, Univ of Pennsylvania School of Medicine* (2, 1938)
- Rigdon, R H**, M D Univ of Texas Med Branch, Galveston *Prof of Exper Pathology* (4, 1941)
- Riggs, Douglas S**, M D Harvard Med School, Boston, Mass *Instr in Pharmacology* (3, 1948)
- Riggs, Lloyd K**, Ph D Natl Dairy Research Labs, Oakdale, L I, N Y *Dir of Nutritional Research* (2, 1929)
- Riker, Walter F, Jr**, M D Cornell Univ Med College, 1300 York Ave, New York City 21 *Asst Prof of Pharmacology* (3, 1947)
- Riley, Richard L**, M D New York Univ Post-Grad Med School, Inst of Industrial Medicine, 477 First Ave, New York City *Assoc in Medicine* (1, 1948)
- Rinehart, James F**, M D Univ of California Med School, Parnassus and Third Aves, San Francisco *Prof of Pathology* (4, 1933)
- Ring, Gordon C**, Ph D Temple Univ Med School, Broad St, Philadelphia, Pa (1, 1933)
- Rioch, David McKenzie**, M D Chestnut Lodge Sanitarium, 500 W Montgomery Ave, Rockville, Md *Dir of Research* (1, 1931)
- Rittenberg, David**, Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Assoc Prof* (2, 1939)
- Ritzman, E G**, A M Univ of New Hampshire, Durham *Research Prof* (5, 1933)
- Rivers, T M**, M D, Sc D Hospital of Rockefeller Inst for Med Research, 66th St and York Ave, New York City *Director* (4, 1925, 6, 1921)
- Robb, Jane Sands**, Sc D, M D Syracuse Univ College of Medicine, 761 Irving Ave, Syracuse, N Y *Assoc Prof of Pharmacology* (1, 1924)
- Robbie, W A**, Ph D State Univ of Iowa College of Medicine, Dept of Ophthalmology, Iowa City *Research Assoc, Prof of Ophthalmology and Physiology* (1, 1947)
- Robbins, Benjamin Howard**, M S, M D Vanderbilt Univ School of Medicine, Nashville, Tenn *Assoc Prof of Pharmacology* (3, 1936)
- Robbins, Mary L**, Ph D George Washington Univ School of Medicine, 1335 H St, N W, Washington 5, D C *Asst Prof of Bacteriology* (6, 1946)
- Roberts, Edward F**, M D, Ph D Wyeth, Inc, 1600 Arch St, Philadelphia 3, Pa *Dir of Clinical Investigation* (6, 1932)
- Roberts, Joseph T**, M D, Ph D Veterans Admin Hospital, Batavia, N Y *Chief of Med Service* (1, 1947)
- Roberts, Lydia J**, Ph D Univ of Puerto Rico, Rio Piedras, P R *Prof and Chairman of Dept of Home Economics* (5, 1933)

- Roberts, Sidney, Ph D Univ of California Med School, Los Angeles *Asst Clinical Prof of Physiological Chemistry* (1, 1946)
- Robertson, Elizabeth Chant, M D , Ph D Univ of Toronto, Toronto, Ontario, Canada *Research Fellow in Pediatrics* (5, 1939)
- Robinson, Charles Summers, Ph D Vanderbilt Univ Med School, Nashville, Tenn *Prof of Biochemistry* (2, 1925)
- Robinson, Elliott S , M D , Ph D R F D 4, Lacomia, N H *Dir of Div of Biologic Labs , Mass Dept of Health (Leave of Absence)* (6, 1935)
- Robinson, G Canby, M D , 4712 Keswick Rd , Baltimore, Md *Excc Sec , Maryland Tuberculosis Assoc* (1R, 1912, 3, 1921)
- Robinson, Harry J , Ph D Merck Inst for Therapeutic Research, Rahway, N J *Asst Dir* (3, 1946)
- Robinson, Herbert E , Ph D Swift and Co , Research Labs , Union Stock Yards, Chicago 9, Ill *Asst Dir of Research* (5, 1947)
- Robinson, Howard W , Ph D Broad and Ontario Sts , Philadelphia, Pa *Prof of Physiological Chemistry, Temple Univ School of Medicine* (2, 1929)
- Robinson, Sid, Ph D Indiana Univ Med School, Bloomington *Prof of Physiology* (1, 1941)
- Robinson, True W , Ph D Wright-Patterson Air Force Base, Aero-Med Lab , Dayton, Ohio *Chief of Metabolism Unit* (1, 1948)
- Roblin, Richard O , Jr , Ph D 1937 W Main St , Stamford, Conn *Dir of Chemotherapy Div , American Cyanamid Co* (2, 1946, 6, 1947)
- Robschert-Robbins, F S , Ph D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Assoc in Pathology* (1, 1925, 4, 1930)
- Rodbard, Simon, Ph D Michael Reese Hospital, Cardiovascular Dept , 29th and Ellis Aves , Chicago, Ill (1, 1942)
- Roe, Joseph Hiram, Ph D George Washington Univ School of Medicine, Washington, D C *Prof of Biochemistry* (2, 1927, 5, 1933)
- Roeder, Kenneth D , M A Tufts College, Medford, Mass *Assoc Prof of Biology* (1, 1942)
- Roepke, Martin Henry, Ph D Univ Farm, St Paul, Minn *Prof of Veterinary Medicine* (3, 1937)
- Rogers, Fred T , Ph D , M D Dallas Med and Surgical Clinic, 4105 Live Oak St , Dallas 1, Tex (1, 1917)
- Rogoff, Julius M , M D , Sc D Univ of Pittsburgh School of Medicine, Pittsburgh, Pa *Prof of Endocrinology* (1, 1916, 3, 1916)
- Ronzoni, Ethel, Ph D Washington Univ Med School, St Louis 4, Mo *Asst Prof of Biological Chemistry* (2, 1923)
- Roos, Albert, M D Washington Univ School of Medicine, Dept of Physiology, Euclid Ave and Kingshighway, St Louis 10, Mo *Instr in Physiology and Surgery* (1, 1949)
- Root, Howard F , M D 44 Dwight St , Brookline, Mass *Assoc in Medicine, Harvard Med School* (5, 1933)
- Root, Raymond W , Ph D College of the City of New York, Dept of Biology, 139th St and Convent Ave , New York City *Assoc Prof of Biology, Head of Div of Physiology* (1, 1949)
- Root, Walter S , Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St , New York City 32 *Prof of Physiology* (1, 1932)
- Rosahn, Paul D , M D 92 Grand St , New Britain, Conn *Pathologist, New Britain General Hospital, Assoc Clinical Prof of Pathology, Yale Univ School of Medicine* (4, 1934)
- Rose, Harry M , M D Columbia Univ College of Physicians and Surgeons, 630 W 168th St , New York City 32 *Assoc Prof of Bacteriology* (6, 1949)
- Rose, Jerzy E , M D Johns Hopkins Univ Med School, Dept of Physiology, 710 N Washington St , Baltimore 5, Md *Asst Prof of Physiology and Psychiatry* (1, 1949)
- Rose, William C , Ph D Univ of Illinois, Urbana *Prof of Biochemistry* (2, 1912, 5, 1933)
- Rosenblueth, Arturo, M D Instituto Nacional de Cardiologia, Calzada de la Piedad 300, Mexico D F , Mexico (1, 1932)
- Rosenfeld, Morris, M D Johns Hopkins School of Medicine, Baltimore, Md *Assoc Prof of Pharmacology and Exper Therapeutics* (3, 1934)
- Rosenow, Edward C , M D Longview State Hospital, Research Dept , Cincinnati 16, Ohio (4, 1913, 6, 1915)
- Rosenthal, Otto, M D Univ of Pennsylvania School of Medicine, Philadelphia, Pa *Asst Prof of Cancer Research, Harrison Dept of Surgical Research* (2, 1946)
- Rosenthal, Sanford M , M D Natl Insts of Health, Bethesda, Md *Sr Pharmacologist USPHS* (3, 1925)
- Rosenthal, S R , M D , Ph D Univ of Illinois College of Medicine, Chicago *Assoc Prof of Preventive Medicine and Public Health, Dir , Institution for Tuberculosis Research of Univ of Illinois* (1, 1948, 4, 1941)
- Ross, Joseph F , M D Robert Dawson Evans Memorial, 65 E Newton St , Boston, Mass *Physician, Massachusetts Memorial Hospital, Assoc Prof of Medicine, Boston Univ School of Medicine* (4, 1941)
- Rossiter, R J , Ph D Univ of Western Ontario, London, Ontario, Canada *Prof of Biochemistry* (2, 1948)
- Rostorfer, Howard Hayes, Ph D Indiana Univ , Dept of Physiology, Bloomington *Asst Prof of Physiology* (1, 1946)

- Roth, Grace M , Ph D Mayo Clinic, Rochester, Minn *Assoc in Clin Physiology* (1, 1939)
- Roth, L W , Ph D Abbott Research Labs , Dept of Pharmacology, North Chicago, Ill *Research Pharmacologist* (1, 1947)
- Rothchild, Irving, Ph D Ohio State Univ , Dept of Obstetrics and Gynecology, Univ Hospital, Columbus, Ohio (1, 1949)
- Rothmund, Paul W K , Dr -Ing Antioch College, Yellow Springs, Ohio *Prof of Chemistry, Research Chemist, C F Kettering Foundation* (2, 1940)
- Rothstein, A , Ph D Univ of Rochester School of Medicine and Dentistry, Rochester 7, N Y *Asst Prof in Pharmacology, Chief of Physiological Section, Pharmacological Div , Atomic Energy Project* (1, 1949)
- Rous, Peyton, M D , Sc D Rockefeller Inst for Med Research, York Ave at 66th St , New York City *Member Emeritus* (4, 1913)
- Routh, Joseph I , Ph D State Univ of Iowa, Iowa City *Assoc Prof of Biochemistry* (2, 1942)
- Rovenstone, Emery Andrew, M D 477 First Ave , New York City *Prof of Anesthesia, New York Univ , Dir of Div of Anesthesia, Bellevue Hospital* (3, 1944)
- Rowntree, Jennie I , Ph D Univ of Washington, Seattle *Prof of Home Economics* (5, 1933)
- Rowntree, L G , M D , Sc D DuPont Bldg , E Flagler St at 2nd Ave , Miami, Fla (1, 1911, 2, 1910, 3, 1908, 4, prior to 1920, 5, 1933)
- Rubenstein, Boris B , Ph D , M D Michael Reese Hospital, Dept of Metabolic and Endocrine Research, E 59th St and Ellis Ave , Chicago, Ill (1, 1934)
- Rubin, Saul H , Ph D Hoffmann-LaRoche, Inc , Nutley 10, N J *Dir of Nutrition Labs* (2, 1947, 5, 1947)
- Ruch, Theodore C , Ph D Univ of Washington, 204B Physiology Hall, Seattle 5 *Prof of Physiology and Biophysics* (1, 1933)
- Ruckman, Isaac, Ph D Cincinnati General Hospital, Cincinnati, Ohio *Asst Prof of Bacteriology* (6, 1948)
- Rusch, Harold Paul, M D Univ of Wisconsin Med School, McArdle Memorial Lab , Madison 6 *Prof of Oncology, Dir of Lab* (4, 1940)
- Rushmer, Robert F , M D Univ of Washington School of Medicine, Dept of Physiology and Biophysics, Seattle 5 *Asst Prof* (1, 1949)
- Rusoff, Louis L , Ph D Louisiana State Univ , Baton Rouge *Assoc Dairy Nutritionist in Exper Station and Assoc Prof of Nutrition* (5, 1948)
- Russell, Jane A , Ph D Yale Univ School of Medicine, 333 Cedar St , New Haven, Conn *Instr in Physiological Chemistry* (1, 1939)
- Russell, Walter C , Ph D New Jersey Agricultural Exper Station, Rutgers Univ , New Brunswick *Research Specialist and Prof of Agricultural Biochemistry* (2, 1932, 5, 1933)
- Ryan, Andrew Howard, M D Chicago Med School, 710 S Wolcott Ave , Chicago, Ill *Assoc Prof of Physiology and Pharmacology* (1, 1912)
- Rytand, David A , M D Stanford Univ Hospital, San Francisco 15, Calif *Assoc Prof of Medicine, Stanford Univ School of Medicine* (3, 1946)
- Sabin, Albert, M D Children's Hospital Research Foundation, Cincinnati, Ohio *Prof of Research Pediatrics, Univ of Cincinnati* (6, 1946)
- Sacks, Jacob, Ph D , M D Brookhaven Natl Lab , Biology Dept , Upton, L I , N Y *Scientist* (1, 1948, 3, 1933)
- Sah, Peter P T , Ph D Univ of Calif , Div of Pharmacology and Exper Therapeutics, San Francisco *Lecturer in Pharmacology* (3, 1941)
- Sahyun, Melville, Ph D Sahyun Research Lab , 1425 Bath St , Santa Barbara, Calif (2, 1932)
- Sakami, Warwick, Ph D Western Reserve Univ School of Medicine, 2109 Adelbert Rd , Cleveland 6, Ohio *Asst Prof of Biochemistry* (2, 1949)
- Salk, Jonas E , M D Univ of Pittsburgh School of Medicine, Pittsburgh, Pa *Assoc Research Prof of Bacteriology* (6, 1947)
- Salmon, W D , A.M Alabama Polytechnic Inst , Auburn *Animal Nutritionist* (2, 1929, 5, 1933)
- Salter, William T , M D Yale Univ School of Medicine, 333 Cedar St , New Haven, Conn *Prof of Pharmacology* (1, 1933, 3, 1942, 5, 1934)
- Sammis, Florence E , M D 133 E 58th St , New York City *Physician, Allergy, OPD, New York Hospital* (6, 1943)
- Sampson, John J , M D 2211 Post St , San Francisco, Calif (1, 1932)
- Sampson, Myra M , Ph D Smith College, Northampton, Mass *Prof of Zoology* (5, 1935)
- Samuels, Leo T , Ph D Univ of Utah Med School, Salt Lake City *Prof and Head of Dept of Biological Chemistry* (2, 1941, 3, 1937, 5, 1949)
- Sandels, Margaret R , Ph D Florida State Univ , Tallahassee *Dean of School of Home Economics, Prof of Nutrition* (5, 1933)
- Sandiford, Irene, Ph.D Billings Hospital, Univ of Chicago, Chicago, Ill *Asst Prof of Medicine* (2, 1925, 5, 1933)
- Sandow, Alexander, Ph D Washington Square College of Arts and Sciences, New York Univ , New York City *Assoc Prof of Biology* (1, 1945)
- Sandweiss, David J , M D 9739 Dexter Ave , Detroit, Mich *Instr in Clin Medicine, Wayne Univ College of Medicine, Physician, Harper Hospital (OPD)* (1, 1944)
- Sanford, Arthur H , M A , M D Clin Labs , Mayo Clinic, Rochester, Minn *Head of Div of Clin Labs* (6, 1920)

- Santos, Francisco O , Ph D Univ of the Philippines, Los Banos, Laguna *Prof and Head of Dept of Agricultural Chemistry, College of Agriculture* (5, 1936)
- Saphir, Otto, M D Michael Reese Hospital, 29th St and Ellis Ave , Chicago 16, Ill *Pathologist, Clin Prof of Pathology, Univ of Illinois Med School* (4, 1927)
- Saphra, Ivan, M D Beth Israel Hospital, New York City *Assoc Bacteriologist* (6, 1946)
- Sarett, Herbert P , Ph D Tulane Med School, 1430 Tulane Ave , New Orleans 13, La *Asst Prof of Biochemistry* (2, 1946, 5, 1947)
- Sarnoff, Stanley J , M D Harvard School of Public Health, Dept of Physiology, 55 Shattuck St , Boston 15, Mass *Asst Prof of Physiology* (1, 1949)
- Saslow, George, Ph D , M D Washington Univ Med School, Dept of Neuropsychiatry, 640 S Kingshighway, St Louis, Mo *Asst Prof of Psychiatry, Assoc Physician to the Student Health Service* (1, 1936)
- Satterfield, G Howard, A M Univ of North Carolina, State College of Agriculture and Engineering, Raleigh *Prof of Biochemistry* (2, 1944, 5, 1941)
- Saul, Leon Joseph, M A , M D Room 1907, 255 S 17th St , Philadelphia 3, Pa (1, 1933)
- Sawyer, Charles H , Ph D Duke Univ School of Medicine, Dept of Anatomy, Durham, N C *Asst Prof of Anatomy* (1, 1949)
- Sawyer, Margaret E MacKay, Ph D 142 Lower Albert St , Kingston, Ontario, Canada (1, 1935)
- Sawyer, Wilbur A , M D 770 Hilldale Ave , Berkeley 8, Calif (4, 1930)
- Saxton, John A , Jr , M D Snodgrass Lab of Pathology and Bacteriology, 1430 Carroll St , St Louis, Mo *Asst Prof of Pathology, Washington Univ School of Medicine, Lab Dir , Hospital Div , City of St Louis* (4, 1944)
- Sayers, George, Ph D Univ of Utah, Dept of Pharmacology, Salt Lake City 1 *Assoc Prof of Pharmacology* (1, 1948 3, 1947)
- Scantlebury, Ronald E , Ph D Natl Insts of Health, Div of Research Grants and Fellowships, Bethesda 14, Md (1, 1948)
- Schales, Otto, D Sc Ochsner Clinic, Prytania and Aline Sts , New Orleans, La *Dir of Chemical Research, Ochsner Foundation, Asst Prof of Biochemistry, Tulane Univ School of Medicine* (2, 1944)
- Scharles, Frederick H , M D 911 Alma Ave , Oakland, Calif (5, 1935)
- Schattenberg, Herbert John, M S , M D Lab of Clin Pathology, 220-222 Med Arts Bldg , San Antonio, Tex *Director* (4, 1940)
- Schenken, John R , M D Univ of Nebraska College of Medicine, Omaha *Prof of Pathology and Bacteriology* (4, 1942)
- Scherago, Morris, D V M Univ of Kentucky, Lexington *Prof and Head of Dept of Bacteriology* (6, 1948)
- Scherp, Henry W , Ph D Univ of Rochester School of Medicine and Dentistry, Rochester 7, N Y *Assoc Prof of Bacteriology and Immunology* (6, 1940)
- Schick, Bela, M D 17 E 84th St , New York City *Pediatrician, Mt Sinai and Sea View Hospitals* (6, 1924)
- Schiffman, Milton J , Ph D Hoffmann-LaRoche, Inc , Chicago, Ill *Research Consultant* (1, 1943)
- Schiller, Alfred A , M D Univ of Illinois College of Medicine, Chicago *Asst Prof of Physiology* (1, 1948)
- Schiller, Joseph, M D , Ph D 55 West 11th St , New York City 11 *Assoc Prof of Physiology, Long Island Univ* (1, 1949)
- Schlenk, Fritz, Ph D Science Hall, Iowa State College, Ames *Prof of Bacteriology* (2, 1942)
- Schlesinger, M J , Ph D , M D Beth Israel Hospital, 330 Brookline Ave , Boston, Mass *Dir of Pathology, Asst Prof of Pathology, Harvard Med School* (4, 1942, 6, 1921)
- Schlomovitz, Benjamin H , M D 1210 Majestic Bldg , 231 W Wisconsin Ave , Milwaukee, Wis (1, 1919)
- Schlumberger, Hans G , M D Ohio State Univ School of Medicine, Columbus *Assoc Prof in Pathology* (4, 1945)
- Schmeisser, Harry C , M D Univ of Tennessee, Memphis *Prof of Pathology* (4, 1937)
- Schmidt, Carl F , M D Univ of Pennsylvania Med School, Philadelphia *Prof of Pharmacology* (1, 1929, 3, 1924)
- Schmidt, C Robert, Ph D , M D Hertzler Clinic, Halstead, Kan *Resident Surgeon* (1, 1940)
- Schmidt, Gerhard, M D Boston Dispensary, 25 Bennett St , Boston, Mass *Sr Research Fellow, Tufts College Med School* (2, 1939)
- Schmidt, L H , Ph D Christ Hospital Inst of Med Research, Cincinnati, Ohio *Dir of Research, Assoc Research Prof of Biochemistry, Univ of Cincinnati College of Medicine* (2, 1936, 3, 1946)
- Schmidt-Nielsen, Bodil, D D S Kettering Lab , Univ of Cincinnati, Cincinnati, Ohio *Research Assoc* (1, 1949)
- Schmidt-Nielsen, Knut, Ph D Kettering Lab , Univ of Cincinnati, Cincinnati, Ohio *Asst Prof* (1, 1949)
- Schmitt, Francis Otto, Ph D Dept of Biology, Massachusetts Inst of Technology, Cambridge *Prof of Biology* (1, 1930)
- Schmitt, Otto H , Ph D Univ of Minnesota, Dept of Physics, Minneapolis 14 *Assoc Prof of Zoology and Physics* (1, 1947)

- Schneider, Charles L , M D , Ph D Herman Kiefer Hospital, Detroit 2, Mich *Resident in Obstetrics, College of Medicine, Wayne Univ* (1, 1949)
- Schneider, Edward C , Ph D 25 Gordon Place, Middletown, Conn *Prof Emeritus of Biology, Wesleyan Univ* (1R, 1912, 2, 1912)
- Schneider, Howard A , Ph D Rockefeller Inst for Med Research, 66th Street and York Avenue, New York City 21 *Associate* (5, 1947)
- Schneerson, S Stanley, M D Mount Sinai Hospital, 2 East 100th St , New York City 29 *Assoc Bacteriologist* (6, 1946)
- Schoenbach, Emanuel B , M D Johns Hopkins School of Hygiene, 615 N Wolfe St , Baltimore, Md *Assoc Prof of Preventive Medicine* (6, 1941)
- Schoepfle, Gordon M , Ph D Washington Univ School of Medicine, St Louis, Mo *Asst Prof of Physiology* (1, 1943)
- Scholander, P F , M D , Ph D Swarthmore College, Dept of Zoology, Swarthmore, Pa *Research Biologist* (1, 1947)
- Schradieck, Constant E , M D General Delivery, Germantown, Philadelphia, Pa (6, 1921)
- Schreiner, Oswald, Ph D U S Dept of Agriculture, Bureau of Plant Industry, Washington 25, D C *Chief of Div of Soil Fertility Investigations* (2, 1908)
- Schroeder, E F , Ph D G D Searle & Co , P O Box 5110, Chicago 80, Ill *Research Biochemist* (2, 1938)
- Schroeder, Henry A , M D Dept of Internal Medicine, Hypertension Div , Washington Univ , 640 S Kingshighway, St Louis 10, Mo (1, 1947)
- Schubert, Maxwell, Ph D Dept of Therapeutics, New York Univ College of Medicine, 477 First Ave , New York City 10 *Research Assoc in Therapeutics* (3, 1947)
- Schuck, Cecelia, Ph D Purdue Univ , Dept of Home Economics, Lafayette, Ind *Prof of Nutrition* (5, 1941)
- Schueler, Fred W , Ph D State Univ of Iowa College of Medicine, Dept of Pharmacology, Iowa City *Instructor* (3, 1949)
- Schultz, Edwin William, M D Stanford Univ , 743 Cooksey Lane, Calif *Prof of Bacteriology and Exper Pathology* (4, 1927, 6, 1928)
- Schultz, Fred H , Jr , Ph D Commercial Solvents Corp , Terre Haute, Ind *Research Pharmacologist* (3, 1948)
- Schultze, Max O , Ph D Univ of Minnesota, Div of Agricultural Biochemistry, St Paul 8 *Professor* (2, 1938)
- Schweigert, B S , Ph D Univ of Chicago, American Meat Inst Foundation, 939 E 57th St , Chicago 37, Ill *Asst Prof of Biochemistry, Biochemist, American Meat Inst Foundation* (2, 1949)
- Schweizer, Malvina, Ph D New York Univ , Washington Square College of Arts and Sciences, New York City *Instr in Biology* (1, 1944)
- Schwerma, Henry, Ph D Los Angeles County General Hospital, 1200 N State St , Los Angeles 33, Calif (1, 1948)
- Schwert, George W , Ph D Duke Univ School of Medicine, Dept of Biochemistry, Durham, N C *Asst Prof* (2, 1949)
- Schwimmer, Sigmund, Ph D Enzyme Research Lab , 800 Buchanan St , Albany 6, Calif *Chemist, U S Bureau of Agricultural and Industrial Chemistry* (2, 1947)
- Scott, Charles Covert, Ph D , M D Inlow Clinic, Shelbyville, Ind (3, 1945)
- Scott, David Alymer, Ph D Connaught Labs , Univ of Toronto, Toronto 5, Ontario, Canada *Research Member* (2, 1935)
- Scott, Ernest L , Ph D 64 South St , Bogota, N J *Assoc Prof Emeritus of Physiology, Columbia Univ* (1R, 1914, 2, 1915)
- Scott, Frederick Hughes, Ph D , M B Univ of Minnesota, Minneapolis *Prof Emeritus of Physiology* (1R, 1908, 2, 1909)
- Scott, James K , M D Univ of Rochester School of Medicine and Dentistry, Atomic Energy Project, Rochester 7, N Y *Chief, Pathology Section, AEC, Assoc in Pathology* (4, 1949)
- Scott, John C , Ph D Hahnemann Med College, Philadelphia Pa *Prof and Head of Dept of Physiology* (1, 1936)
- Scott, R W , M A , M D City Hospital, Cleveland, Ohio *Physician in Chief, Prof of Clin Medicine, Western Reserve Univ* (1, 1917, 3, 1917)
- Scott, V Brown, Ph D , M D Inlow Clinic, Shelbyville, Ind *Internist, Div of Medicine* (1, 1941)
- Scott, W W , Ph D , M D Brady Urological Inst , Johns Hopkins Hospital, Baltimore 5, Md (1, 1943)
- Scrimshaw, Nevin S , Ph D , M D Instituto de Nutricion de Centro America y Panama Guatemala City, Guatemala, Central America *Dir of Div of Nutrition, Pan American Sanitary Bureau* (5, 1949)
- Scudi, John V , Ph D Pyridium Corp , Nepera Park, Yonkers 2, N Y *Dir of Research* (2, 1942, 5, 1945)
- Seager, Lloyd D , M S , M D Woman's Med College of Pennsylvania, East Falls, Philadelphia *Prof of Pharmacology and Toxicology* (3, 1939)
- Sealock, Robert R , Ph D Iowa State College, Ames *Assoc Prof of Chemistry* (2, 1940, 5, 1941)
- Seastone, C V , Jr , M D Univ of Wisconsin Med School, Madison *Prof and Chairman of Med Bacteriology* (6, 1939)

- Sebrell, W H , Jr , M D Natl Insts of Health, Bethesda 14, Md *Dir , Exper Biology and Medicine Inst , Professorial Lecturer on Nutrition, George Washington Univ* (2, 1938, 5, 1937)
- Seecof, David P , M D 1970 Daly Ave , Bronx, New York City (4, 1927)
- Seegal, Beatrice Carrie, M D Columbia Univ College of Physicians and Surgeons, 630 W 168th St , New York City 32 *Assoc Prof of Bacteriology* (6, 1949)
- Seegal, David, M D Maimonides Hospital, Brooklyn, N Y *Dir of Med Services* (6, 1930)
- Seegers, Walter H , Ph D Wayne Univ College of Medicine, 1512 St Antoine St , Detroit 26, Mich *Prof of Physiology* (1, 1947, 2, 1941)
- SeEVERS, Maurice Harrison, Ph.D , M D Univ of Michigan, Ann Arbor *Prof of Pharmacology* (1, 1933, 3, 1930)
- Segaloff, Albert, M D Alton Ochsner Med Foundation, 3503 Prytania St , New Orleans, La *Dir of Endocrine Research* (4, 1946)
- Seibert, Florence B , Ph D Univ of Pennsylvania, Henry Phipps Inst , 7th and Lombard Sts , Philadelphia *Assoc Prof of Biochemistry* 2, 1925)
- Seidell, Atherton, Ph D 2301 Connecticut Ave , Washington D C *Special Expert, Natl Insts of Health* (2, 1924)
- Seifter, Joseph, M D Wyeth Inst of Applied Biochemistry, Philadelphia, Pa *Dir of Research* (3, 1940)
- Seifter, Sam, Ph D Long Island College of Medicine, 350 Henry St , Brooklyn 2, N Y *Assoc Prof of Biochemistry* (2, 1946)
- Selkurt, Ewald E , Ph D Western Reserve Univ School of Medicine, Cleveland 6, Ohio *Assoc Prof of Physiology* (1, 1945)
- Selle, Wilber Arthur, Ph D Univ of Texas Med School, Galveston *Prof of Physiology* (1, 1938)
- Sellers, E A , M D , Ph D Univ of Toronto, Dept of Physiology, Toronto, Ontario, Canada *Assoc Prof of Physiology, Assoc Prof in Banting and Best Dept of Med Research* (1, 1947)
- Selye, Hans, M D , Ph D Inst of Exper Medicine and Surgery , Univ of Montreal, Montreal, Quebec, Canada *Prof and Dir* (1, 1934)
- Sendroy, Julius, Jr , Ph D Naval Med Research Inst , Natl Naval Med Center, Bethesda 14, Md *Chief Chemist* (2, 1928)
- Sevag, M G , Ph D Univ of Pennsylvania School of Medicine, Dept of Bacteriology, Philadelphia *Assoc Prof Biochemistry in Bacteriology* (2, 1949, 6, 1941)
- Sevringhaus, Elmer L , M A , M D Hoffmann La Roche, Inc, Nutley 10, N J *Dir of Clin Research, Clin Prof of Medicine, New York Med College* (2, 1923, 5, 1939)
- Shaffer, Morris F , Ph D Tulane Univ School of Medicine, Dept of Bacteriology, New Orleans, La *Professor* (4, 1939, 6, 1937)
- Shaffer, Philip A , Ph D Washington Univ Med School, St Louis 10, Mo *Distinguished Service Prof of Biological Chemistry* (2, 1906, 5, 1935)
- Shanes, Abraham M , Ph D Georgetown Univ School of Medicine, Dept of Physiology and Biophysics, Washington 7, D C (1, 1946)
- Shank, Robert E , M D Washington Univ School of Medicine, St Louis 10, Mo *Prof of Preventive Medicine* (2, 1947)
- Shannon, James A , Ph D , M D Squibb Inst for Med Research, New Brunswick, N J *Director* (1, 1933, 3, 1945)
- Shapiro, Herbert, Ph D Henry Phipps Inst , 7th and Lombard Sts , Philadelphia 47, Pa *Research Assoc* (1, 1937)
- Sharpless, George R , Sc D Lederle Labs , Pearl River, N Y *Research Biochemist* (5, 1942)
- Shaw, J C , Ph D Univ of Maryland, Dept of Dairy Husbandry, College Park, Md *Professor* (1, 1947)
- Shaw, James H , Ph D Harvard School of Dental Medicine, Boston, Mass *Assoc in Nutrition* (5, 1948)
- Shaw, Myrtle, Ph D 11 S Lake Ave Albany, N Y *Sr Bacteriologist, Div of Labs and Research, N Y State Dept of Health* (6, 1937)
- Shay, Harry, M D Temple Univ School of Medicine, Philadelphia, Pa *Dir of Fels Research Inst and Clin Prof of Medicine* (1, 1944)
- Shear, M J , Ph D Natl Cancer Inst , Bethesda, 14, Md *Chief of Chemotherapy Section* (2, 1930)
- Sheard, Charles, Ph D Mayo Foundation, Rochester, Minn *Chief of Div of Physics and Biophysical Research, Prof of Physiological Optics and Biophysics, Univ of Minnesota* (1, 1925)
- Sheehan, Donal, M D , D Sc New York Univ , Bellevue Med Center, 477 First Ave , New York City (1, 1938)

- Shemin, David, Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St , New York City 32 *Assoc Prof of Biochemistry* (2, 1944)
- Sheppard, Fay, M S Univ of Oklahoma Med School, Oklahoma City *Instr in Biochemistry* (2, 1936)
- Sherman, Henry C , Ph D Columbia Univ , New York City *Mitchell Prof Emeritus of Chemistry* (1R, 1923, 2, 1906 5, 1933)
- Sherman, William C , Ph D Ralston Purina Co , St Louis, Mo *Head of Biological Labs* (5, 1949)
- Sherwin, Carl Paxson, Sc D , M D , Dr P H 6 Carstensen Rd Scarsdale, N Y *Dir of Metabolic Service, St Vincent's Hospital, Assoc Physician, French Hospital* (2, 1917)

- Sherwood, Noble P , Ph D , M D Univ of Kansas, 517 Snow Hall, Lawrence *Prof of Bacteriology* (6, 1928)
- Sherwood, Thomas Cecil, Ph D , M D 1824 Robert St , New Orleans, La Southern Baptist Hospital *Staff Member, Internal Medicine* (1, 1938)
- Shettles, Landrum B , Ph D , M D Columbia Univ , College of Physicians and Surgeons, Box 330, 622 W 168th St , New York City (1, 1946)
- Shideman, Frederick E , Ph D Univ of Michigan, Dept of Pharmacology, Ann Arbor *Instr in Pharmacology* (3, 1944)
- Shimkin, Michael Boris, M D Univ of California Med School, San Francisco *Dir , Lab of Exper Oncology* (4, 1940)
- Shunowara, George Y , Ph D Ohio State Univ College of Medicine, Dept of Pathology, Columbus *Assoc Prof , Dept of Pathology, Chem Pathologist, Univ Hospital* (2, 1949)
- Shipley, Reginald A , M D Western Reserve Univ School of Medicine, Cleveland 6, Ohio *Asst Prof of Medicine* (1, 1945)
- Shupley, Robert E , M D Lilly Lab for Clin Research, Indianapolis City Hospital, Indianapolis, Ind (1, 1945)
- Shive, William, Ph D Univ of Texas, Austin *Assoc Prof of Chemistry* (2, 1948)
- Shlaer, Simon, Ph D Box 1663, Los Alamos, N M (1, 1938)
- Shock, Nathan W , Ph D Baltimore City Hospitals, Baltimore 24, Md *Chief, Section on Gerontology, USPHS, Natl Insts of Health, Bethesda, Md* (1, 1942)
- Shoemaker, Harold A , Ph D Univ of Oklahoma School of Medicine, 801 E 13th St , Oklahoma City *Asst Dean, Prof of Pharmacology* (3, 1941)
- Shope, Richard E , M D Ridge Road, Kingston N J *Merck Inst for Therapeutic Research* (4, 1934)
- Shorr, Ephraim, M D New York Hospital, 525 E 68th St , New York City *Asst Attending Physician, Asst Prof of Medicine, Cornell Univ Med College* (1, 1931, 3, 1942)
- Shrigley, E W , Ph D , M D Indiana Univ Med Center, Dept of Microbiology, 1040-1232 W Michigan St , Indianapolis 7 (6, 1946)
- Shwartzman, Gregory, M D 230 E 50th St , New York City *Head of Dept of Bacteriology, Mount Sinai Hospital, Prof of Bacteriology, Columbia Univ* (4, 1929, 6, 1930)
- Sichel, F J M , Ph D Univ of Vermont College of Medicine, Burlington *Prof and Chairman of Dept of Physiology and Biophysics* (1, 1939)
- Sickles, Grace M , B A 2201 Twelfth St , Troy, N Y *Assoc Bacteriologist, Div of Labs and Research, New York State Dept of Health* (6, 1932)
- Sickles, Gretchen R , A B New York State Dept of Health, Div of Labs and Research, Albany, N Y *Asst Bacteriologist* (6, 1937)
- Siebenmann, Charles O , D Eng Connaught Med Research Labs , Univ of Toronto, Toronto 5, Ontario, Canada *Research Assoc* (3, 1946)
- Siebert, Walter J , M D Lutheran Hospital, St Louis, Mo *Dir of Labs , Pathologist* (4, 1932)
- Silber, Robert H , Ph D Merck Inst , Rahway, N J *Head, Dept of Biochemistry* (2, 1948)
- Silberberg, Martin, M D Snodgras Lab of Pathology, City Hospital, 1430 Carroll St , St Louis 4, Mo *Instr in Pathology, Washington Univ School of Medicine* (4, 1944)
- Silberberg, Ruth, M D Snodgras Lab of Pathology, City Hospital, 1430 Carroll St , St Louis 4, Mo *Instr in Pathology, Washington Univ School of Medicine* (4, 1944)
- Silvette, Herbert, Ph D Meharry Med College, Dept of Pharmacology, Nashville, Tenn *Visiting Prof of Pharmacology* (1, 1943, 3, 1940)
- Simmonds, Sofia, Ph D Yale Univ , Osborn Botanical Lab , New Haven 11, Conn *Asst Prof of Microbiology* (2, 1948)
- Simonds, James P , Ph D , M D 2033 W Morse Ave , Chicago 45, Ill *Prof Emeritus of Pathology, Northwestern Univ Med School* (4, prior to 1920)
- Simonsen, Daisy G , Ph D Los Angeles County Hospital, 1200 N State St , Los Angeles 33, Calif *Chemist and Toxicologist, Instr in Medicine, Univ of Southern California Med School* (2, 1949)
- Simonson, Ernst, M D Univ of Minnesota, Lab of Physiological Hygiene, Stadium South Tower, Minneapolis 14 *Assoc Prof of Physiology* (1, 1941)
- Simpson, Miriam E , Ph D , M D Univ of California, Div of Anatomy, Berkeley *Prof of Anatomy* (1, 1946)
- Singal, Sam A , Ph D Univ of Georgia School of Medicine, Augusta *Assoc Prof of Biochemistry* (2, 1948)
- Singer, Thomas P , Ph D Western Reserve Univ , Cleveland, Ohio *Asst Prof of Biochemistry* (2, 1948)
- Sizer, Irwin W , Ph D Massachusetts Inst of Technology, Cambridge *Assoc Prof of Physiology* (1, 1944)
- Skinner, John Taylor, Ph D The Grapette Co , Camden, Ark *Chief Chemist* (2, 1946)
- Slaughter, Donald, M D Univ of South Dakota School of Med Sciences, Vermillion *Dean* (3, 1938)
- Smadel, Joseph Edwin, M D Army Med Dept , Dept of Virus and Rickettsial Diseases, Re-

- search and Grad School, Washington 12, D C *Scientific Dir* (4, 1940, 6, 1937)
- Small, James C, M D 101 S 39th St, Philadelphia, Pa *Assoc in Medicine, Univ of Pennsylvania Grad School of Medicine* (4, 1927)
- Smetana, Hans F, M D Armed Forces Inst of Pathology, 7th St and Independence Ave, Washington 25, D C (4, 1934)
- Smith, Arthur H, Ph D Wayne Univ College of Medicine, Detroit 26, Mich *Prof of Physiological Chemistry* (1, 1923, 2, 1921, 5, 1933)
- Smith, Austin Edward, M D American Med Assoc, 535 N Dearborn St, Chicago, Ill *Acting Sec of Council on Pharmacy and Chemistry, Research Assoc, Univ of Chicago, Dept of Pharmacology* (3, 1942)
- Smith, Clarence A, Ph D Standard Brands, Inc, 595 Madison Ave, New York City *Technical Dir, Agricultural Dept* (1, 1921)
- Smith, David T, M D Duke Hospital, Durham, N C *Prof of Bacteriology and Assoc Prof of Medicine* (5, 1943, 6, 1949)
- Smith, Dietrich Conrad, Ph D Univ of Maryland School of Medicine, Lombard and Greene Sts, Baltimore *Assoc Prof of Physiology* (1, 1937)
- Smith, Douglas E, Ph D Argonne Natl Lab, P O Box 5207, Chicago 80, Ill (1, 1947)
- Smith, Edwin L, Ph D Univ of Texas Dental School, Houston *Prof of Physiology* (1, 1948)
- Smith, Elnor Van Dorn, Ph D 5 Middle St, Hadley, Mass *Assoc Prof of Bacteriology, Smith College* (6, 1940)
- Smith, Elizabeth R B, Ph D % Dr, Paul K Smith, 1335 H St, N W, Washington 5, D C (2, 1938)
- Smith, Emul L, Ph D Univ of Utah School of Medicine, Salt Lake City 1 *Assoc Prof of Biochemistry* (2, 1946)
- Smith, Erma A, Ph D, M D 1600 W Maypole St, Chicago 12, Ill (1, 1928)
- Smith, George H, Ph D Yale Univ School of Medicine, New Haven, Conn *Prof of Immunology and Asst Dean, Chairman of Dept of Bacteriology, Yale Univ* (6, 1918)
- Smith, H P, M S, M D Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City 32 *Delafield Prof of Pathology* (1, 1937, 4, 1925)
- Smith, Homer W, Sc D New York Univ, Bellevue Med Center, 477 First Ave, New York City *Prof of Physiology* (1, 1923, 2, 1930)
- Smith, Janice M, Ph D Univ of Illinois, Dept of Home Economics, Urbana *Prof and Chief of Nutrition* (5, 1947)
- Smith, John R, A M, M D Washington Univ School of Medicine, St Louis 10, Mo *Asst Prof of Medicine* (1, 1947)
- Smith, Lawrence Weld, M D 119 E 26th St, New York City 10 (4, 1927)
- Smith, Lee Irvin, Ph D Univ of Minnesota School of Chemistry, Minneapolis 14 *Prof and Chief of Div of Organic Chemistry* (2, 1942)
- Smith, Margaret Cammack, Ph D El Encanto Estates, Tuscon, Ariz (5, 1933)
- Smith, Maurice I, M D Natl Insts of Health, Bethesda 14, Md *Principal Pharmacologist, USPHS* (1, 1920, 3, 1916)
- Smith, Paul K, Ph D George Washington Univ School of Medicine, Dept of Pharmacology, 1335 H St, N W, Washington 5, D C *Prof of Pharmacology and Exec Officer of Dept* (2, 1937, 3, 1937)
- Smith, Paul W, Ph D Univ of Oklahoma School of Medicine, 801 E 13th St, Oklahoma City *Assoc Prof of Pharmacology* (1, 1933)
- Smith, Philip Edward, Ph D Columbia Univ, 630 W 168th St, New York City 32 *Prof of Anatomy* (1, 1923)
- Smith, Ralph G, M D, Ph D Tulane Univ, Station 20, New Orleans, La *Prof of Pharmacology* (3, 1929)
- Smith, R Blackwell, Jr, Ph D Med College of Virginia, Richmond 19 *Lecturer in Pharmacology* (3, 1944)
- Smith, Sedgwick E, Ph D Cornell Univ, Dept of Animal Husbandry, Ithaca, N Y *Animal Physiologist* (5, 1945)
- Smith, Susan Gower, M A Duke Univ, Durham, N C *Assoc in Dept of Medicine and Nutrition, School of Medicine* (5, 1939)
- Smith, Wilbur Kenneth, M D Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Assoc. Prof of Anatomy* (1, 1939)
- Smith, Willie W, Ph D Natl Insts of Health, Bethesda, Md *Physiologist* (1, 1941)
- Smithburn, Kenneth C, M D Rockefeller Foundation, 49 W 49th St, New York City *Staff Member, International Health Div* (6, 1937)
- Smolens, Joseph, B S Wyeth Research Inst, 900 N Broad St, Philadelphia, Pa *Head of Dept of Immunology* (6, 1943)
- Smythe, C V, Ph D 5000 Richmond St, Philadelphia, Pa *Head of Biochemistry, Rohm & Haas Co* (2, 1934)
- Snape, William J, M D Jefferson Med College, Philadelphia, Pa *Assoc in Physiology* (1, 1948)
- Snell, Albert M, M D Mayo Clinic, Rochester, Minn *Head of Section on Medicine, Prof in Medicine, Mayo Foundation Grad School, Univ of Minnesota* (4, 1930)
- Snell, Esmond E, Ph D Univ of Wisconsin, Madison 6 *Prof of Biochemistry* (2, 1942, 5, 1946)
- Snider, Ray S, Ph D Northwestern Univ School of Medicine, 303 E Chicago Ave, Chicago 11, Ill *Assoc Prof of Anatomy* (1, 1949)
- Snyder, Franklin Faust, M D Boston Lying-In Hospital, Boston, Mass (1, 1936)

- Sobel, Albert E**, Ph D Jewish Hospital of Brooklyn, Prospect Place and Classon Ave, Brooklyn, N Y *Head of Dept of Chemistry, Adjunct Prof of Chemistry, Polytechnic Inst of Brooklyn* (2, 1939)
- Sobin, Sidney S**, M D, Ph D 405 N Bedford Drive, Beverly Hills, Calif *Research Assoc in Physiology, Univ of Southern California* (1, 1949)
- Sobotka, Harry H**, Ph D Mount Sinai Hospital, Fifth Ave and 100th St, New York City 29 *Head of Dept of Chemistry* (2, 1932, 5, 1933)
- Solandt, Donald Young**, M D, Ph D Univ of Toronto, Toronto, Ontario, Canada *Prof of Physiology in charge of Biophysics, Faculty of Medicine, Prof and Head of Dept of Hygiene, School of Hygiene* (1, 1937)
- Sollmann, Torald**, M D 14327 Superior Rd, Cleveland, Ohio *Dean and Prof Emeritus of Pharmacology, Western Reserve Univ* (1R, 1902, 2, 1906, 3, 1908)
- Solotorovsky, Morris**, Ph D 203 W 5th St, Plainfield, N J *Merck Inst for Therapeutic Research, Rahway, N J, Research Assoc in Chemotherapy* (6, 1946)
- Somogyi, Michael**, Ph D 216 S Kingshighway, St Louis, Mo *Biochemist, Jewish Hospital of St Louis* (2, 1927)
- Soskin, Samuel**, M D, Ph D Michael Reese Hospital, 29th St and Ellis Ave, Chicago 16, Ill *Med Dir and Dir of Research Inst, Dean, Postgrad School* (1, 1930, 5, 1933)
- Soule, Malcolm H**, Sc D Univ of Michigan, Ann Arbor *Prof of Bacteriology, and Chairman of Dept of Bacteriology* (4, 1927, 6, 1925)
- Spain, Will C**, M D 116 E 53rd St, New York City *Clin Prof of Medicine, Post-Grad Med School, Columbia Univ* (6, 1923)
- Spealman, C R**, Ph D Dept of Commerce, Civil Aeronautics Admin, Washington 25, D C (1, 1940)
- Specht, Heinz**, Ph D Natl Insts of Health, Bethesda, Md *Scientist, USPHS* (1, 1941)
- Speirs, Mary**, Ph D Georgia Agricultural Experiment Station, Experiment *Head of Dept of Home Economics* (5, 1949)
- Sperry, Roger W**, Ph D Univ of Chicago, Dept of Anatomy, Chicago 37, Ill (1, 1945)
- Sperry, Warren M**, Ph D New York State Psychiatric Inst, 722 W 168th St, New York City 32 *Principal Research Biochemist, Assoc Prof of Biological Chemistry, Columbia Univ* (2, 1929, 5, 1933)
- Spiegel, Ernest A**, M D Temple Univ School of Medicine, Broad and Ontario Sts, Philadelphia, Pa *Prof of Exper Neurology* (1, 1938)
- Spiegel-Adolf, Mona**, M D Temple Univ School of Medicine, Broad and Ontario Sts, Philadelphia, Pa *Prof and Head of Dept of Colloid Chemistry* (2, 1933)
- Spiegelman, Sol**, Ph D Univ of Minnesota Med School, Dept of Physiology, Minneapolis 14 (1, 1946)
- Spies, Tom D**, M D Hillman Hospital, Birmingham, Ala *Dir of Nutrition Clinic, Prof of Nutrition and Metabolism, Northwestern Univ Med School* (3, 1941, 4, 1940, 5, 1938)
- Spink, Wesley W**, M D Univ of Minnesota Hospital, Minneapolis *Assoc Prof of Medicine, Univ of Minnesota Med School* (6, 1940)
- Spohn, Adelaide**, Ph D Elizabeth McCormick Memorial Fund, 848 N Dearborn St, Chicago, Ill *Nutritionist* (5, 1933)
- Spoor, Herbert J**, Ph D, M D Bristol Myers Co, New York City *Asst Dir of Med Div* (1, 1945)
- Sprent, J F A**, Ph D Univ of Toronto, 43 Queens Park, Toronto 5, Ontario, Canada *Asst Prof, Sr Research Fellow, Ontario Research Foundation* (6, 1949)
- Sprinson, David B**, Ph D Columbia Univ College of Physicians and Surgeons, Dept of Biochemistry, 630 W 168th St, New York City 32 *Research Assoc* (2, 1949)
- Sproul, Edith E**, M D Columbia Univ College of Physicians and Surgeons, Dept of Pathology, 630 W 168th St, New York City 32 (4, 1941)
- Sprunt, Douglas H**, M D, M S Univ of Tennessee, Memphis *Prof of Pathology, Head of Dept of Pathology and Bacteriology* (4, 1934, 6, 1936)
- Stacy, Ralph W**, Ph D Ohio State Univ, Dept of Physiology, Hamilton Hall, Columbus 10 *Asst Prof* (1, 1949)
- Stadie, William C**, M D 821 Maloney Clinic, 36th and Spruce Sts, Philadelphia 4, Pa *John Herr Musser Prof of Research Medicine, Univ of Pennsylvania* (2, 1922)
- Stainsby, Wendell J**, M D Geisinger Memorial Hospital, Danville, Pa *Chief Physician* (6, 1930)
- Stanley, Wendell M**, Ph D Univ of California, Berkeley 4 *Prof and Chairman of Div of Biochemistry, Dir of Virus Lab* (2, 1936)
- Stannard, James Newell**, Ph D Univ of Rochester Med School, Atomic Energy Project, Rochester 7, N Y *Assoc Prof of Radiation Biology* (1, 1938)
- Stare, Fredrick J**, Ph D, M D 695 Huntington Ave, Boston 15, Mass *Prof of Nutrition, Harvard Univ* (2, 1937, 5, 1942)
- Starr, Isaac**, M D Hospital of the Univ of Pennsylvania, Philadelphia *Hartzell Prof of Research Therapeutics* (1, 1929, 3, 1942)

- Stavraky, George W , M D Univ of Western Ontario, Med School, London, Ontario, Canada *Assoc Prof of Physiology* (1, 1937, 3, 1944)
- Stead, Eugene A , Jr , M D Duke Univ , Dept of Medicine, Durham, N C (1, 1945)
- Stearns, Genevieve, Ph D State Univ of Iowa, College of Medicine, Iowa City *Research Prof of Pediatrics* (2, 1932, 5, 1937)
- Steel, Matthew, Ph D Long Island College of Medicine, 350 Henry St , Brooklyn, N Y *Prof of Biological Chemistry* (2, 1909)
- Steele, J Murray, M D Thurd (N Y U) Research Div , Goldwater Memorial Hospital, Welfare Island, New York City *Assoc Prof of Medicine, New York Univ , Dir of 3rd Med Div , Welfare Hospital* (1, 1936)
- Steenbock, Harry, Ph D Univ of Wisconsin, Madison *Prof of Biochemistry* (2, 1912, 5, 1933)
- Steggerda, F R , Ph D Univ of Illinois, 416 Natural History Bldg , Urbana *Assoc Prof of Physiology* (1, 1934)
- Stehle, Raymond Louis, Ph D McGill Univ , Faculty of Medicine, Montreal Quebec, Canada *Prof of Pharmacology* (2, 1920, 3, 1922)
- Steigman, Alex J , M S , M D Natl Foundation for Infantile Paralysis, 120 Broadway, New York City 5 (6, 1949)
- Steigmann, Frederick, M S , M D 348 S Hamlin Ave , Chicago, Ill *Assoc in Medicine, Univ of Illinois, College of Medicine, Assoc Attending Physician, Cook County Hospital* (3, 1942)
- Steiman, S E , Ph D , M D 23 Broad St , Lynn, Mass *Asst Physician, Metropolitan State Hospital, Waltham, Mass* (1, 1939)
- Stein, George J , Ph D 406th Med General Lab APO 500 %P M , San Francisco, Calif (6, 1947)
- Stein, William Howard, Ph D Rockefeller Inst for Med Research, 66th and York Ave , New York City 21 *Assoc in Chemistry* (2, 1946)
- Steinbach, H Burr, Ph D Univ of Minnesota, Dept of Zoology, Minneapolis (1, 1934)
- Steinberg, Bernhard, M D Toledo Hospital Inst of Med Research, Toledo, Ohio *Dir of Toledo Hospital Inst , Chief Pathologist and Dir of Labs , Toledo Hospital* (4, 1928, 6, 1946)
- Steiner, Paul E , M D Univ of Chicago, Chicago, Ill *Prof of Pathology* (4, 1939)
- Steinhardt, Jacinto, Ph D 1548 East-West Highway, Silver Spring, Md *Dir , Operations Evaluation Group, Mass Inst of Technology* (2, 1939)
- Steinhaus, Arthur H , Ph D 5315 Drexel Ave , Chicago, Ill *Prof of Physiology, George Williams College, Hyde Park* (1, 1928)
- Stekol, Jakob A , D Sc Lankenau Hospital Research Inst , Philadelphia 30, Pa *Assoc Member* (2, 1936)
- Stern, Kurt G , Ph D Polytechnic Inst of Brooklyn, 99 Livingston St , Brooklyn 2, N Y *Adjunct Prof of Biochemistry* (2, 1938)
- Stetten, DeWitt, Jr , M D , Ph D Harvard Med School, 25 Shattuck St , Boston 15, Mass *Chief, Div of Nutrition and Physiology* (2, 1944)
- Stetten, Marjorie R , Ph D Harvard Med School, 25 Shattuck St , Boston 15, Mass *Assoc , Div of Nutrition and Physiology* (2, 1947)
- Stevens, S Smith, Ph D Harvard Univ , Memorial Hall, Cambridge, Mass *Prof of Psychology, Div of Psychological Labs* (1, 1937)
- Stewart, Dorothy R , Ph D Rockford College, Rockford, Ill (1, 1947)
- Stewart, Fred W , M D Memorial Hospital, 444 E 68th St , New York City *Pathologist, Prof of Pathology, Cornell Med School* (4, 1928)
- Stewart, Harold L , M D Natl Cancer Inst , Bethesda, Md *Chief of Pathology Section* (4, 1936)
- Stewart, Winifred Bayard, M D , M A 1930 Spruce St , Philadelphia, Pa *Prof of Neurology, Woman's Med College of Pennsylvania* (1, 1941)
- Stickney, J Clifford, Ph D West Virginia Univ School of Medicine Morgantown *Assoc Prof of Physiology* (1, 1944)
- Stiebeling, Hazel K , Ph D U S Dept of Agriculture Washington, D C *Chief, Bureau of Human Nutrition and Home Economics* (5, 1933)
- Stier, Theodore J B , Ph D Indiana Univ Med School, Bloomington *Assoc Prof of Physiology* (1, 1938)
- Still, Eugene U , Ph D 820 So Orange, Sarasota, Fla (1, 1929)
- Stillman, Ernest G , M D 45 E 75th St , New York City (6, 1930)
- Stimmel, Benjamin F , Ph D Rees-Stealy Med Research Fund, Ltd , 2001 Fourth Ave , San Diego, Calif *Research Biochemist* (2, 1947)
- Stock, Aaron H , M D Univ of Pittsburgh School of Medicine, Pittsburgh, Pa *Asst Prof of Bacteriology and Immunology* (6, 1947)
- Stockton, Andrew Benton, M D 655 Sutter St , San Francisco, Calif (3, 1931)
- Stoerk, Herbert C , M D Merck Inst for Therapeutic Research, Rahway, N J *Head of Dept of Cancer Research* (4, 1948)
- Stoesser, Albert V , M D , Ph D Univ of Minnesota Med School, 1409 Willow St , Loring Park, Minneapolis *Clin Assoc Prof of Pediatrics* (6, 1949)
- Stohlman, Edward F , LL B Natl Insts of Health, Bethesda, Md *Assoc Pharmacologist* (3, 1948)
- Stokinger, Herbert B , Ph D 250 Meigs St , Rochester, N Y *Assoc Prof of Pharmacology and Toxicology* (6, 1947)
- Stokstad, E L Robert, Ph D Lederle Labs , Pearl River, N Y *Chemist* (2, 1947, 5, 1942)
- Stoland, O O , Ph D 1845 Learnard Ave , Lawrence, Kan *Prof of Physiology and Pharmacology, Univ of Kansas* (1, 1913)

- Stone, William E, Ph D Univ of Wisconsin, Dept of Physiology, Madison Asst Prof of Physiology (1, 1945)
- Stormont, Robert T, Ph D, M D Food and Drug Admin, Washington, D C Med Dir, Professional Lecturer in Pharmacology, Georgetown Univ Med School (3, 1941)
- Storvick, Clara A, Ph D Oregon State College, School of Home Economics, Corvallis, Ore Assoc Prof of Foods and Nutrition (5, 1947)
- Stotz, Elmer, H, Ph D Univ of Rochester School of Medicine and Dentistry, Rochester 7, N Y Prof of Biochemistry (2, 1939)
- Stoughton, Roger W, Ph D Mallinckrodt Chemical Works, 3600 N Second St, St Louis, Mo Research Chemist (3, 1939)
- Strong, Frank M, Ph D Univ of Wisconsin, Dept of Biochemistry, Madison 6 Prof of Biochemistry (2, 1941)
- Struck, Harold Carl, Ph D Creighton Univ School of Medicine, 302 N 14th St, Omaha 2, Nebr (1, 1940)
- Stuart, Charles A, Ph D 372 Lloyd Ave, Providence, R I Assoc Prof of Biology, Brown Univ (6, 1935)
- Sturgis, Cyrus Cressey, M D Simpson Memorial Inst, Ann Arbor, Mich Dir of Thomas Henry Simpson Memorial Inst for Med Research, Chairman, Dept of Medicine, Univ of Michigan Hospital (4, 1927)
- Sturkie, Paul D, Ph D Rutgers Univ, New Brunswick, N J Assoc Research Specialist in Poultry Husbandry, Assoc Prof of Poultry Husbandry (1, 1948)
- Stutzman, Jacob W, Ph D, M D Boston Univ School of Medicine, Boston, Mass Assoc Prof of Pharmacology (1, 1946, 3, 1948)
- Sugg, John Y, Ph D Cornell Univ Med College, 1300 York Ave, New York City Assoc Prof of Bacteriology and Immunology (6, 1938)
- Sulkin, S Edward, Ph D Southwestern Med College, Dallas, Tex Prof and Chairman of Dept of Bacteriology and Immunology (6, 1944)
- Sullivan, Michael Xavier, Ph D Chemo-Medical Research Inst, Georgetown Univ, 37th & O Sts, N W, Washington, D C Dir and Research Prof of Chemistry (2, 1909)
- Sulzberger, Marion B, M D 999 5th Ave, New York City Assoc Clin Prof of Dermatology and Syphilology, N Y Post-Grad Med School of Columbia Univ, Assoc Dir of Skin and Cancer Unit of N Y Post-Grad Hospital (6, 1936)
- Summerson, William H, Ph D Med Div, Army Chemical Center, Md Chief, Biochemistry Section (2, 1942)
- Sumner, J B, Ph D Cornell Univ, Ithaca, N Y Dir, Enzyme Chemistry Lab (2, 1919)
- Sunderman, F William, M D, Ph D Univ of Texas, M D Anderson Hospital, 2310 Baldwin St, Houston 6 Prof of Exper Medicine and Clin Pathology, Dir of Clin Research (2, 1931)
- Sundstroem, Edward S, M D Univ of California, Berkeley 4 Prof Emeritus of Biochemistry (2, 1919)
- Sure, Barnett, Ph D Univ of Arkansas, Fayetteville Head of Dept and Prof of Agricultural Chemistry (2, 1923, 5, 1933)
- Sutherland, George F, M D Duke Univ School of Medicine, Durham, N C (1, 1939)
- Sutton, T Scott, Ph D Ohio State Univ, Columbus Prof, Dir of Inst of Nutrition and Food Technology (5, 1936)
- Svirbely, Joseph L, Ph D Mound Lab, Monsanto Chemical Co, Miamisburg, Ohio Pharmacologist (3, 1945)
- Swain, Robert E, Ph D 634 Mirada Ave, Stanford Univ, Calif Prof Emeritus of Chemistry (2, 1909)
- Swann, Howard G, Ph D Univ of Texas Med School, Dept of Physiology, Galveston Asst Prof of Physiology (1, 1940)
- Swanson, Pearl P, Ph D Iowa State College, Ames Prof of Foods and Nutrition, Dept of Foods and Nutrition (5, 1933)
- Swanson, William W, M S, M D 2376 E 71st St, Chicago, Ill Asst Prof of Pediatrics, Northwestern Univ (2, 1938)
- Sweeney, H Morrow, Ph D Aero-Med Lab, Wright Field, Dayton, Ohio (1, 1939)
- Swift, Homer, M D, D Sc 888 Park Ave, New York City Member, Rockefeller Inst for Med Research, Physician to Hospital of Rockefeller Inst for Med Research (6, 1920)
- Swift, Raymond W, Ph D Pennsylvania State College, State College Prof of Dept of Animal Nutrition (5, 1934)
- Swingle, Wilbur Willis, Ph D Princeton Univ, Princeton, N J Prof of Biology (1, 1924)
- Swinyard, Ewart A, Ph D Univ of Utah, Salt Lake City Prof of Pharmacy, School of Pharmacy, Lecturer in Pharmacology, School of Medicine (3, 1948)
- Sydenstricker, V P, M D Univ of Georgia School of Medicine, Augusta Prof of Medicine (5, 1944)
- Sykes, Joseph F, Ph D U S Dept of Agriculture, Bureau of Dairy Industry, Beltsville, Md Physiologist (1, 1942)
- Syvertson, Jerome T, M D Univ of Minnesota, Minneapolis, Minn Prof and Head, Dept of Bacteriology and Immunology (4, 1940, 6, 1947)
- Szego, Clara M, Ph D Univ of California, Med School, Los Angeles Asst Clin Prof of Biophysics (1, 1946)
- Szent-Gyorgyi, Albert, Ph D, M D Natl Insts of Health, Bethesda 14, Md (2, 1949)

- Szepsenwol, Josel, M D Emory Univ School of Medicine, Emory University, Ga *Asst Prof of Anatomy* (1, 1948)
- Tabor, Herbert, M D Natl Insts of Health, Pharmacology Section, Bethesda 14, Md *Sr Asst Surgeon, USPHS* (3, 1947)
- Tager, Morris Western Reserve Univ, Cleveland, Ohio *Dept of Microbiology* (6, 1948)
- Tainter, M L, M A, M D Sterling-Winthrop Research Inst, 33 Riverside Ave, Rensselaer, N Y *Director* (1, 1929, 3, 1927)
- Talbot, Samuel Armstrong, Ph D Johns Hopkins Hospital Baltimore, Md *Instr in Physiological Optics, Johns Hopkins Univ* (1, 1940)
- Tahaferro, William H, Ph D Univ of Chicago, Dept of Bacteriology, Chicago, Ill *Ehakim H Moore Distinguished Service Prof of Parasitology and Dean of Div of Biological Sciences* (6, 1930)
- Tannenbaum, Albert, M D Michael Reese Hospital, 29th St & Ellis Ave, Chicago, Ill *Dir of Dept of Cancer Research* (4, 1942)
- Tarver, Harold, Ph D Univ of California, Div of Biochemistry, Berkeley 4 *Asst Prof of Biochemistry* (2, 1947)
- Tashiro, Shiro, Ph D, M D Univ of Cincinnati College of Medicine, Cincinnati, Ohio *Prof of Biochemistry* (1, 1913, 2, 1913)
- Tatum, Arthur L, Ph D, M D Service Memorial Inst, Univ of Wisconsin, Madison *Prof of Pharmacology* (1, 1913, 3, 1919)
- Tatum, Edward L, Ph D Stanford Univ, School of Biological Sciences, Stanford University, Calif *Prof of Biology* (2, 1947)
- Tauber, Henry, Ph D V D Research Lab, U S Marine Hospital, Staten Island, N Y *Biochemist, USPHS* (2, 1933)
- Taylor, A N, Ph D Univ of Oklahoma School of Medicine, Oklahoma City *Asst Prof and Chairman of Dept of Physiology* (1, 1948)
- Taylor, Alton R, Ph D Parke, Davis & Co, Detroit 32, Mich *Sr Researcher, Research Div* (2, 1947, 6, 1943)
- Taylor, Craig L, Ph D Univ of California, Dept of Engineering, Los Angeles *Assoc Prof of Engineering* (1, 1945)
- Taylor, Fred A, Ph D 320 E North Ave, N S, Pittsburgh, Pa *Biochemist, Singer Memorial Lab* (2, 1933)
- Taylor, Haywood M, Ph D Duke Univ School of Medicine, Durham, N C *Assoc Prof of Biochemistry and Toxicology, Biochemist and Toxicologist to Duke Hospital* (4, 1942)
- Taylor, Henry Longstreet, Ph D Univ of Minnesota, School of Public Health, Minneapolis *Asst Prof of Physiological Hygiene* (1, 1944)
- Taylor, John Fuller, Ph D Washington Univ School of Medicine, Euclid and Kingshighway St Louis, Mo *Asst Prof of Biological Chemistry* (2, 1944)
- Taylor, M Wight, Ph D New Jersey Agricultural Exper Station, New Brunswick *Assoc Biochemist in Nutrition and Assoc Prof of Agricultural Biochemistry, Rutgers Univ* (5, 1944)
- Taylor, Norman Burke, M D Univ of Toronto, Toronto 5, Ontario, Canada *Prof of Physiology* (1, 1922)
- Taylor, Richard M, Rockefeller Foundation, 66th St and York Ave, New York City (6, 1949)
- Taylor, Robert D, M D Clinical Research Div, Cleveland Foundation, Cleveland 6, Ohio *Member* (1, 1945)
- Teague, Robert S, Ph D, M D Medical College of Alabama, Dept of Pharmacology and Physiology, Birmingham 5 *Assoc Prof of Physiology and Pharmacology* (3, 1942)
- Templeton, Roy D, B S 5630 South Flores, San Antonio, Tex (1, 1935)
- Ten Broeck, Carl, M D Rockefeller Inst for Med Research, Dept of Animal and Plant Pathology, Princeton, N J *Director* (4R, 1932, 6, 1924)
- Tepperman, Jay, M D Syracuse Univ School of Medicine, Dept of Pharmacology, Syracuse, N Y *Assoc Prof of Pharmacology* (1, 1944)
- Terplan, Kornel L, M D Univ of Buffalo School of Medicine, Buffalo, N Y *Prof of Pathology* (4, 1935)
- Terry, Roger, M D Univ of Rochester School of Medicine and Dentistry, Dept of Pathology, Rochester 7, N Y *Instr in Pathology* (4, 1949)
- Thannhauser, S J, M D, Ph D Pratt Diagnostic Hospital, 30 Bennet St, Boston, Mass *Prof of Clin Medicine, Tufts Med School, Assoc Chief of Pratt Diagnostic Hospital* (2, 1937)
- Thatcher, Jonathan S, Ph D Ohio State Univ, Dept of Physiology, Hamilton Hall, Columbus 10 *Instructor* (1, 1949)
- Thauer, Rudolf, M D 3226 Fuller St, Philadelphia 36, Pa *Physiologist, Research Worl in N A M C U S Navy* (1, 1949)
- Thayer, Sidney Allen, Ph D 1402 S Grand Blvd, St Louis 4, Mo *Assoc Prof of Biochemistry, St Louis Univ School of Medicine* (2, 1933)
- Thienes, Clinton H, M D, Ph D Univ of Southern California School of Medicine, Los Angeles *Prof of Pharmacology* (3, 1928)
- Thomas, Arthur W, Ph D Columbia Univ, New York City 27 *Prof of Chemistry* (2, 1924)
- Thomas, Byron H, Ph D Iowa State College, Ames *Prof and Head of Animal Chemistry and Nutrition, Iowa Agric Exper Station* (5, 1933)
- Thomas, Caroline Bedell, M D Johns Hopkins Hospital, Baltimore, Md *Assoc Prof of Medicine, Johns Hopkins Univ School of Medicine* (1, 1939)

- Thomas, J Earl**, M D Jefferson Med College, Philadelphia, Pa *Prof of Physiology* (1, 1922, 3, 1924)
- Thompson, Marvin R**, Ph D 67 Greenwich Ave, Stamford, Conn (3, 1944)
- Thompson, Randall L**, Sc D, M D Indiana Univ, Med Center, Indianapolis 7 *Prof of Bacteriology* (6, 1937)
- Thompson, William R**, Ph D 1 Darrock Rd, Delmar, N Y *Sr Biochemist, Div of Labs and Research, New York State Dept of Health* (2, 1934)
- Thomson, David Landsborough**, Ph D McGill Univ, Montreal, Quebec, Canada *Prof of Biochemistry and Dean of Faculty of Grad Studies and Research* (2, 1929)
- Thorn, George Widmer**, M D Peter Bent Brigham Hospital, Boston, Mass *Prof of Medicine, Harvard Univ* (1, 1939)
- Thorp, W T S**, D V M Natl Insts of Health, Bethesda, Md *Veterinary Pathologist* (4, 1948)
- Tidwell, Herbert C**, Ph D Southwestern Med College, 2211 Oak Lawn Ave, Dallas, Tex *Prof and Chairman of Dept of Biochemistry* (2, 1948)
- Tillett, William S**, M D New York Univ College of Medicine, Dept of Bacteriology, 477 First Ave, New York City *Prof of Medicine* (6, 1927)
- Tilt, Jennie**, Ph D Florida State Univ, Tallahassee *Prof of Physiological Chemistry and Nutrition* (5, 1937)
- Tipson, R Stuart**, Ph D Mellon Inst of Industrial Research, Univ of Pittsburgh, Pittsburgh, Pa *Sr Fellow, Dept of Research in Pure Chemistry* (2, 1937)
- Tipton, Samuel R**, Ph D Univ of Tennessee, Dept of Zoology, Knoxville *Prof of Zoology* (1, 1940)
- Tislow, Richard**, M D Schering Corp, Bloomfield, N J *Dir of Biological Labs* (1, 1944)
- Titus, Harry W**, Ph D Lime Crest Research Lab, R F D 1, Newton, N J *Technical Counsellor and Dir of Nutritional Research* (2, 1929, 5, 1933)
- Tobias, Julian M**, M D Univ of Chicago, Chicago, Ill *Instr in Physiology* (1, 1944)
- Tocantins, Leandro Maués**, M D Jefferson Med College, Philadelphia, Pa *Assoc Prof of Medicine* (1, 1939)
- Todd, Wilbert R**, Ph D Univ of Oregon Med School, Portland, Ore *Assoc Prof of Biochemistry* (2, 1948, 5, 1948)
- Todhunter, Elizabeth Neige**, Ph D Univ of Alabama, University *Prof of Nutrition* (5, 1939)
- Toennies, Gerrit**, Ph D Lankenau Hospital, Philadelphia 30, Pa *Sr Member, Inst for Cancer Research* (2, 1934)
- Tolle, Chester D**, Ph D Federal Security Agency, Food and Drug Admin, Washington, D C *Sr Biochemist* (5, 1942)
- Toman, James E P**, Ph D Univ of Utah School of Medicine, Dept of Pharmacology and Physiology, Salt Lake City (1, 1945)
- Tomlinson, Wray Joseph**, M D Fort Logan Veterans Hospital, Denver, Colo *Chief of Labs, Asst Prof of Pathology, Univ of Colorado School of Medicine* (4, 1945)
- Tompkins, Edna H**, M D Yale Univ, Lab of Applied Physiology, 52 Hillhouse Ave, New Haven, Conn *Research Assoc, Assoc Prof* (4, 1941)
- Toomey, John A**, LL B City Hospital, Div of Contagious Diseases, 3395 Scranton Rd, Cleveland 9, Ohio *Prof of Pediatrics, Western Reserve Univ School of Medicine* (6, 1943)
- Torda, Clara**, Ph D, M D Cornell Univ Med College, New York City *Research Fellow in Pharmacology* (1, 1943, 3, 1944)
- Toth, Louis A**, Ph D Louisiana State Univ School of Medicine, Dept of Physiology, New Orleans 13 *Assoc Prof of Physiology* (1, 1940)
- Totter, John R**, Ph D Univ of Arkansas School of Medicine, Little Rock *Assoc Prof, Dept of Biochemistry* (2, 1946)
- Tourtellotte, Dee**, D Sc Charles B Knox Gelatin Co, 4th and Erie Sts, Camden, N J *Head of Nutrition Lab* (5, 1935)
- Tower, Sarah Sheldon**, M D, Ph D Johns Hopkins Univ, Baltimore, Md *Instr in Psychiatry* (1, 1932)
- Trager, William**, M D, Ph D Rockefeller Inst for Med Research, Dept of Animal and Plant Pathology, Princeton, N J *Associate* (4, 1947)
- Traub, Frederick B**, M D 205 E 82nd St, New York City 28 *Assoc Bacteriologist, Jewish Hospital of Brooklyn* (6, 1946)
- Travell, Janet**, M D Cornell Univ Med College, New York City *Asst Prof of Clin Pharmacology* (3, 1933)
- Travis, Lee Edward**, Ph D Univ of Southern California, Los Angeles *Prof of Psychology and Dir of Psychological Center, Major, YAAF (Yuma, Ariz)* (1, 1929)
- Treadwell, Carleton R**, Ph D George Washington Univ School of Medicine, Dept of Biochemistry, 1335 H St, N W, Washington, D C *Assoc Prof of Biochemistry* (2, 1944, 5, 1949)
- Treffers, Henry P**, Ph D Yale Med School, Dept of Immunology, New Haven, Conn *Assoc Prof of Immuno-chemistry* (6, 1942)
- Trimble, Harry C**, Ph D Harvard Med School, 25 Shattuck St, Boston, Mass *Asst Prof of Biological Chemistry* (2, 1929, 5, 1936)
- Tuft, Louis H**, M D 1530 Locust St, Philadelphia, Pa *Asst Prof of Medicine, Temple Univ Med School, Chief of Clinic of Allergy and Applied Immunology, Temple Univ Hospital* (6, 1928)
- tum Suden, Caroline**, Ph D % J L Wolff, 38 Crane Rd, Scarsdale, N Y (1, 1936)

- Tunturi, Archie Robert, Ph D Univ of Oregon Med School, Portland Asst Prof of Anatomy (1, 1946)
- Tuohy, Edward B, M S, M D Mayo Clinic, Rochester, Minn Asst Prof of Anesthesiology, Mayo Foundation (3, 1941)
- Turner, Abby H, Ph D Mount Holyoke College, South Hadley, Mass Prof of Physiology (1, 1928)
- Tuttle, Waid Wright, Ph D State Univ of Iowa, Iowa City Prof of Physiology (1, 1925)
- Tweedy, Wilbur R, Ph D Veterans Admin Hospital, Radioisotope Unit, Hines, Ill Assoc Director (2, 1931)
- Tyler, Albert, Ph D California Inst of Technology, Pasadena, Calif Assoc Prof of Embryology (6, 1946)
- Tyler, David B, Ph D Carnegie Inst of Washington, Dept of Embryology, Wolfe and Madison Sts, Baltimore 5, Md Member of Staff (1, 1943)
- Umbreit, Wayne W, Ph D Merck Inst for Therapeutic Research, Rahway, N J Head of Dept of Enzyme Chemistry (2, 1947)
- Unna, Klaus R W, M D Univ of Illinois College of Medicine, 1853 W Polk St, Chicago 12, Ill Assoc Prof, Dept of Pharmacology (1, 1941, 3, 1944, 5, 1942)
- Upton, Morgan, Ph D Rutgers Univ, Dept of Psychology, New Brunswick, N J (1, 1934)
- Urban, Frank, Ph D, M D 302 Northern Bldg, Green Bay, Wis (2, 1932)
- Utter, Merton F, Ph D Western Reserve Univ, Dept of Biochemistry, Cleveland, Ohio Assoc Prof of Physiological Chemistry (2, 1946)
- Vahlteich, Ella McCollum, Ph D 310 Walnut St, Englewood, N J (5, 1933)
- Valle, J R, M D Escola Paulista de Medicina, Caixa Postal 144-A, Sao Paulo, Brazil Prof of Pharmacology (3, 1947)
- Vanderscheer, James, Ch E 136 Linwood Ave, Ridgewood, N J Research Chemist, Lederle Labs (6, 1946)
- Van Dyke, H B, Ph D, M D Columbia Univ College of Physicians and Surgeons, 630 W 168th St New York City 32 Hosack Prof of Pharmacology (1, 1925, 3, 1927)
- van Harreveld, Anthonie, M A, M D California Inst of Technology, Pasadena Assoc Prof of Physiology (1, 1941)
- Van Liere, Edward J, M D, Ph D West Virginia Univ School of Medicine, Morgantown Prof of Physiology and Dean (1, 1927)
- Van Middlesworth, Lester, Ph D Univ of Tennessee, Memphis Instr in Physiology (1, 1948)
- Van Slyke, Donald D, Ph D, M D Brookhaven Natl Lab, Upton, L I, N Y Asst Dir in Charge of Depts of Biology and Med Sciences, Member Emeritus, Rockefeller Inst (2, 1908)
- van Wagenen, Gertrude, Ph D Yale Univ School of Medicine, New Haven, Conn Assoc Prof (1, 1932)
- van Wagtendonk, Willem J, Ph D Indiana Univ Dept of Zoology, Bloomington Assoc Prof (2, 1946)
- Van Winkle, Walton, Jr, M D American Med Assoc, 535 N Dearborn St, Chicago 10, Ill (3, 1939)
- Varney, Philip L Washington Univ School of Medicine, St Louis, Mo Asst Prof of Bacteriology (6, 1948)
- Vars, Harry M, Ph D Univ of Pennsylvania Med School, Harrison Dept of Surgical Research, Philadelphia Assoc Prof of Physiological Chemistry (2, 1935, 5, 1935)
- Velick, Sidney Frederick Washington Univ School of Medicine, Dept of Biochemistry, Euclid Ave and Kingshighway, St Louis 10, Mo Asst Prof of Biochemistry (2, 1946)
- Vennesland, Birgit, Ph D Univ of Chicago, Dept of Biochemistry, Chicago, Ill Assoc Prof (2, 1944)
- Venning, Eleanor H, Ph D Univ Clinic, Royal Victoria Hospital, Pine Ave, Montreal, Quebec, Canada Asst Prof of Medicine, McGill Univ (2, 1938)
- Vestling, Carl Swensson, Ph D Univ of Illinois, Noyes Lab, Urbana, Ill Asst Prof of Biochemistry (2, 1946)
- Vickery, Hubert B, Ph D Connecticut Agric Exper Station, New Haven Biochemist in Charge, Dept of Biochemistry, Lecturer in Physiological Chemistry, Yale Univ (2, 1923)
- Victor, Joseph, M D Camp Detrick, Frederick, Md Chief, Pathology Branch (4, 1935)
- Villee, Claude A, Jr, Ph D Harvard Med School, 25 Shattuck St, Boston 15, Mass Assoc in Biological Chemistry (2, 1948)
- Virtue, Robert W, Ph.D, M D Denver General Hospital, Denver 4, Colo Anesthesiologist (2, 1939)
- Visscher, Frank E, Ph D Upjohn Co, Kalamazoo 99, Mich Research Scientist, Dept of Pharmacology and Endocrinology (1, 1947)
- Visscher, Maurice B, Ph D, M D Univ of Minnesota, Minneapolis Prof and Head of Dept of Physiology (1, 1927)
- Voegtlin, Carl, Ph D Univ of Rochester Med School, Rochester, N Y Lecturer in Pharmacology (1R, 1908, 2, 1908, 3, 1908)
- von Haam, Emmerich, M D Ohio State Univ, Columbus Prof of Pathology (4, 1938)
- Von Oettingen, W F, M D, Ph D Natl Insts of Health, Lab of Physical Biology, Exper Biology and Medicine Inst, Bethesda, Md Chief Industrial Toxicologist (3, 1925)
- Voris, LeRoy, Ph D Natl Research Council, 2101 Constitution Ave, Washington 25, D C Exec Sec, Food and Nutrition Board (5, 1949)

- Vorwald, Arthur J , Ph D , M.D Saranac Lake, N Y *Dir , Edward L Trudeau Foundation and Saranac Lab* (4, 1937)
- Vos, Bert J , Ph D , M D Food and Drug Admin , Div of Pharmacology, Washington, D C *Assoc Pharmacologist* (3, 1941)
- Wachstein, Max, M D St Catherine's Hospital, Brooklyn, N Y *Dir of Lab , Research Asst , Mt Sinai Hospital* (4, 1947)
- Waddell, James, Ph D E I duPont de Nemours & Co , New Brunswick, N J *Dir of Biological Lab* (2, 1930, 5, 1935)
- Wadsworth, Augustus B , M D Manchester, Vt (4, 1935, 6, 1920)
- Waelsch, Heinrich, M D , Ph D 722 West 168th St , New York City 32 *Assoc Research Biochemist, N Y State Psychiatric Inst and Hospital, Assoc Prof of Biochemistry, Columbia Univ* (2, 1941)
- Wagman, Irving H , Ph D Jefferson Med College, Dept of Physiology, Philadelphia 7, Pa *Asst Prof of Physiology* (1, 1946)
- Waisman, Harry A , M D , Ph D Univ of Illinois Med School, 1819 W Polk St , Chicago 12 *Resident Fellow in Pediatrics* (2, 1944)
- Wakeman, Alfred J , Ph D Hatfield Hill Rd , Bethany, Conn *Retired* (2, 1906)
- Wakerlin, George E , Ph D , M D Univ of Illinois Med School, 1853 W Polk St , Chicago *Prof of Physiology* (1, 1933, 3, 1934)
- Wakim, Khalil G , M D , Ph D Mayo Clinic, Rochester, Minn *Consultant, Prof of Physiology, Mayo Foundation* (1, 1942)
- Walcott, William W , Ph D Columbia Univ College of Physicians and Surgeons, Dept of Physiology, New York City 32 *Instructor* (1, 1947)
- Wald, George, Ph D Harvard Univ , Biological Labs , Cambridge, Mass (1, 1934)
- Walker, Arthur M , M.D Univ of Pennsylvania, Philadelphia 4 *Assoc Prof of Pharmacology, Major (M C) , U S A* (1, 1932, 3, 1939)
- Walker, Burnham S , Ph D , M D Boston Univ School of Medicine, 80 E Concord St , Boston, Mass *Prof of Biochemistry* (2, 1940)
- Walker, Harry A , Ph D Emory Univ School of Medicine, Emory University, Ga *Asst Prof of Pharmacology* (3, 1948)
- Walker, Sheppard M , Ph D Washington Univ School of Medicine, St Louis, Mo *Asst Prof of Physiology* (1, 1946)
- Wallen-Lawrence, Zonja, Ph D 4534 W Pine Blvd , St Louis 8, Mo (2, 1937)
- Walter, Annabel W 29 Perry St , New York City 14 *Bacteriologist, New York City Dept of Health, Bureau of Labs* (6, 1946)
- Walter, Carl W , M D Harvard Med School, 25 Shattuck Street, Boston, Mass *Asst Clin Prof of Surgery, Sr Assoc in Surgery, Peter Bent Brigham Hosp* (4, 1942)
- Walters, Orville S , Ph D , M D McPherson, Kan *Physician* (1, 1936)
- Walton, Robert P , Ph.D , M D Med College of the State of South Carolina, Charleston *Prof of Pharmacology* (3, 1933)
- Walton, Seth T , V.M D , Ph D Lab , Veterans Hospital, Oteen, N C *Dir of Labs and Research* (6, 1936)
- Walzer, Matthew, M D 20 Plaza St , Brooklyn, N Y *Attending in Allergy, Jewish Hospital of Brooklyn* (6, 1924)
- Wang, Chu Che, Ph D U S Veterans Admin Hospital, Hines, Ill *In charge of Biochemical Research* (2, 1922, 5, 1933)
- Wang, Shih-Chun, M D , Ph D Columbia Univ College of Physicians and Surgeons, 630 W 168th St , New York City 32 *Assoc Prof of Physiology* (1, 1943)
- Wangeman, Clayton P , M D Broadway Med Center, Associated Anesthesiologists, Seattle, Washington (3, 1946)
- Wangensteen, Owen Harding, M D Univ Hospital, Minneapolis 14, Minn *Prof of Surgery, Univ of Minnesota* (1, 1947, 4, 1931)
- Ward, Arthur A , Jr , M D 8009 W 31st Ave , N E , Seattle, Wash *Asst Prof of Surgery, Head of Div of Neurosurgery, Univ of Washington School of Medicine* (1, 1949)
- Ward, Walter E , Ph D , M D Cutter Labs Fourth and Parker Sts , Berkeley 1, Calif *Assoc Med Dir* (6, 1947)
- Ware, Arnold G , Ph D Wayne Univ College of Medicine, Dept of Physiology, 1512 Antoine St , Detroit 26, Mich *Research Assoc* (2, 1949)
- Warner, Emory D , M D Med Labs Bldg , Iowa City, Ia *Prof of Pathology* (4, 1937)
- Warner, Robert C , Ph D New York Univ College of Medicine, 477 First Ave , New York City 16 *Asst Prof of Chemistry* (2, 1946)
- Warren, Charles O , Ph D , M D The Commonwealth Fund, 41 E 57th St , New York City 22 (1, 1941)
- Warren, James V , M D Emory Univ School of Medicine, Atlanta, Ga *Prof of Physiology, Assoc Prof of Medicine* (1, 1947)
- Warren, Joel 8900 Flower Ave , Silver Spring, Md (6, 1949)
- Warren, Marshall R , Ph D , M D Univ of Tennessee College of Medicine, Memphis *Asst Prof of Pharmacology* (3, 1948)
- Warren, Shields, M D 195 Pilgrim Rd , Boston, Mass *Prof of Pathology, Harvard Med School; Dir , Div of Biology and Medicine, USAEC* (4, 1929)
- Wariman, William Beckman, M D Northwestern Univ , 303 East Chicago Ave , Chicago 11, Ill *Morrison Prof and Chairman of Dept of Pathology* (4, 1940)

- Wasteneys, Hardolph, Ph D Univ of Toronto, Toronto, Ontario, Canada *Prof and Head of Dept of Biochemistry* (2, 1915)
- Waterman, Robert E, B S Schering Corp, 86 Orange St, Bloomfield, N J *Vice-Pres* (2, 1940)
- Waters, Ralph Milton, M D 1300 University Ave, Madison, Wis *Prof of Anesthesia, Univ of Wisconsin* (3, 1937)
- Watson, Cecil J, M D, Ph D University Hospital, Dept of Medicine, Minneapolis, Minn *Prof and Head of Dept of Medicine* (4, 1941)
- Watson, Dennis W Univ of Minnesota Med School, Dept of Bacteriology and Immunology, Minneapolis *Assoc Prof* (6, 1949)
- Watson, John B, Ph D Box 526, Westport, Conn (1, 1907)
- Waud, Russell A, M.D, Ph D Univ of Western Ontario Med School, London, Ontario, Canada *Prof of Pharmacology* (3, 1931)
- Waugh, David F, Ph D Massachusetts Inst of Technology, Dept of Biology and Biological Engineering, Cambridge *Asst Prof of Physical Biology* (1, 1943)
- Way, E Leong, Ph D Univ of California Med Center, San Francisco, Calif *Asst Prof of Pharmacology* (3, 1947)
- Wearn, Joseph T, M D Lakeside Hospital, Cleveland, Ohio *Dir of Medicine, Prof of Medicine, Western Reserve Univ* (1, 1921)
- Weatherby, J H, Ph D Med College of Virginia, Dept of Physiology and Pharmacology, Richmond, Va *Assoc Prof of Pharmacology* (3, 1941)
- Weber, Clarence J, M D, Ph D *Chief, Lab Service* (2, 1931)
- Webster, Bruce, M D, C M Cornell Univ Med College, 1300 York Ave, New York City *Asst Prof of Medicine, Assoc Attending Physician, New York Hospital* (5, 1935)
- Wégria, René, M D Presbyterian Hospital, Dept of Medicine, 622 W 168th St, New York City *Asst Prof of Medicine* (1, 1941)
- Weichert, Charles K, Ph D Univ of Cincinnati, Cincinnati, Ohio *Prof of Zoology* (1, 1935)
- Weil, Alfred J, M D The Bronx Hospital, New York City *Dir of Dept of Bacteriology* (6, 1940)
- Weil, Arthur, M D 952 5th Ave, New York City (4, 1940)
- Weil, Leopold, Ph D U S Dept of Agriculture, Eastern Regional Research Lab, Chestnut Hill Station, Philadelphia 18, Pa *Chemist* (2, 1942)
- Weinhouse, Sidney, Ph D Temple Univ, Research Inst, 3223 N Broad St, Philadelphia 40, Pa *Biochemical Dir* (2, 1948)
- Weir, Everett G, Ph D 231 S 13th Ave, Maywood, Ill (1, 1941)
- Weiser, Russell S, Ph D Univ of Washington School of Medicine, Seattle 5, Washington *Assoc Prof of Microbiology* (6, 1948)
- Weiss, Charles, Ph D, M D Jewish Hospital, York and Tabor Rds, Philadelphia, Pa *Dir of Labs* (4, 1934, 6, 1920)
- Weiss, Emil, M D, Ph D 5036 Bernard St, Chicago, Ill *Pathologist, People's Hospital* (6, 1927)
- Weiss, Paul, Ph D Univ of Chicago, Chicago, Ill *Prof of Zoology* (1, 1936)
- Welch, Arnold D, Ph D, M D Western Reserve Univ School of Medicine, Cleveland, Ohio *Prof of Pharmacology* (3, 1942, 5, 1944)
- Welch, Henry, Ph D U S Food and Drug Admin, Rm 6171 S Agriculture Bldg, Washington, D C, *Chief of Div of Penicillin Control and Immunology* (6, 1932)
- Weld, Charles Beecher, M A, M D Dalhousie Univ, Halifax, N S, Canada *Prof of Physiology* (1, 1936)
- Weld, Mrs Julia T Columbia Univ College of Physicians and Surgeons, 630 W 168th St, New York City *Research Assoc in Pathology* (6, 1920)
- Welker, William H, Ph D 534 N Elmwood Ave, Oak Park, Ill *Prof Emeritus of Biological Chemistry, Univ of Illinois College of Medicine* (2, 1906)
- Weller, Carl Vernon, M D 1130 Fair Oaks Parkway, Ann Arbor, Mich *Prof and Chairman of Dept of Pathology, Univ of Michigan*, (4, 1923)
- Wells, Herbert S, M D Univ of Minnesota, Minneapolis 14 *Prof of Clin Physiology* (1, 1932)
- Wells, Joseph Albert, M D, Ph D Northwestern Univ Med School, Chicago, Ill *Assoc Prof of Pharmacology* (3, 1944)
- Welsh, John H, Ph D Harvard Univ, Biological Labs, 16 Divinity Ave, Cambridge 38, Mass *Assoc Prof of Zoology* (1, 1945)
- Wendel, William B, Ph D Tulane Univ School of Medicine, 6501 St Charles Ave, New Orleans 15, La *Prof and Head of Dept of Biochemistry* (2, 1932)
- Werber, Erna A, Ph.D 44 W 83rd St, New York City *Dir of Research Lab, Jewish Hospital of Brooklyn* (6, 1948)
- Werkman, C H, Ph D Iowa State College, Science Hall, Ames *Prof and Head of Dept of Bacteriology* (2, 1942)
- Werle, Jacob M, M D 2000 W 25th St, Cleveland 13, Ohio *Surgeon* (1, 1943)
- Werner, Harold W, Ph D The Wm S Merrell Co, Lockland Station, Cincinnati, Ohio *Dir Pharmacology Research* (3, 1942)
- Wertemberger, Grace E, Ph D Univ of Indiana, Dept of Physiology, Bloomington (1, 1943)

- Werthessen, Nicholas T, Ph D Shrewsbury, Mass Worcester Foundation for Exper Biology *Sr Fellow* (1, 1946)
- Wescow, W Clarke, M D Cornell Univ Med College, 1300 York Ave, New York City 21 *Instr in Pharmacology* (3, 1949)
- Wesson, Laurence G, Jr, Ph D New York Univ College of Medicine, Dept of Physiology, New York City 16 *Asst Prof* (1, 1949, 2, 1929, 3, 1932)
- West, Edward S, Ph D Univ of Oregon Med School, Portland *Prof of Biochemistry* (2, 1925)
- West, Harold D, Ph D Meharry Med College, Nashville 8, Tenn *Prof and Head of Dept of Biochemistry* (2, 1946)
- Westerfeld, Wilfred Wiedey, Ph D Syracuse Univ College of Medicine, Syracuse 10, N Y *Prof of Biochemistry* (2, 1944)
- Westfall, B A, Ph D Univ of Missouri School of Medicine, Dept of Physiology and Pharmacology, Columbia *Prof of Pharmacology* (1, 1949)
- Weston, Raymond E, M D, Ph D Montefiore Hospital, Med Div, New York City 67 *Asst in Medicine* (1, 1947)
- Weymouth, Frank W, Ph D Stanford Univ, Calif *Prof and Exec of Dept of Physiology* (1, 1917)
- Wheeler, George W, M D New York Hospital, 235 E 73rd St, New York City *Asst Dir* (6, 1920)
- Wheeler, Mary W, M A New York State Dept of Health, Div of Labs and Research, Albany *Assoc Bacteriologist* (6, 1933)
- Wheeler, Homer, M S, M D Univ of Washington, Seattle, Wash *Prof of Medicine* (1, 1919)
- Whipple, George H, M D, Sc D Univ of Rochester, Rochester, N Y *Prof of Pathology and Dean of School of Medicine and Dentistry* (1, 1911, 4, 1913)
- White, Abraham, Ph D Univ of California School of Medicine, Los Angeles 24 *Prof and Chairman of Dept of Physiological Chemistry* (2, 1934, 5, 1937)
- White, Alan G C, Ph D Tulane Univ, Dept of Biochemistry, New Orleans, La *Asst Prof of Biochemistry* (2, 1949)
- White, Colin, B S Univ of Pennsylvania School of Medicine, Dept of Physiology, Philadelphia *Asst Prof* (1, 1949)
- White, Florence R, Ph D % Dr Julius White, Natl Insts of Health, Natl Cancer Inst, Bethesda 14, Md *Biochemist* (2, 1946)
- White, Frank D, Ph D Univ of Manitoba, Faculty of Medicine, Bannatyne Ave, Winnipeg, Manitoba, Canada *Prof of Biochemistry, Biochemist, Winnipeg General Hospital* (2, 1931)
- White, Harvey Lester, M D Washington Univ Med School, St Louis 10, Mo *Prof of Physiology* (1, 1923)
- White, Julius, Ph D Natl Insts of Health, Natl Cancer Inst, Bethesda 14, Md *Head Chemist* (2, 1937)
- White, Paul Dudley, M D Massachusetts General Hospital, Boston, Mass *Physician (in charge of Cardiac Clinics and Lab), Lecturer in Medicine, Harvard Med School* (3, 1921)
- Whitehead, Richard W, M A, M D Univ of Colorado School of Medicine, 4200 E Ninth Ave, Denver *Prof of Physiology and Pharmacology* (1, 1933, 3, 1928)
- Whitehorn, William V, M D Univ of Illinois College of Medicine, Chicago *Asst Prof of Applied Physiology* (1, 1947)
- Whittenberger, James L, M D Harvard School of Public Health, Dept of Physiology, 55 Shattuck St, Boston 15, Mass *Asst Prof and Head of Dept of Physiology* (1, 1949)
- Wiener, Alexander S, M D 64 Rutland Rd, Brooklyn, N Y *Bacteriologist and Serologist to Office of Chief Med Examiner of New York City, Head of Transfusion Div, Jewish Hospital of Brooklyn* (6, 1932)
- Wiersma, Cornelis A G, Ph D California Inst of Technology, Pasadena *Assoc Prof of Physiology* (1, 1941)
- Wiggers, Carl J, M D, Sc D Western Reserve Univ Med School, Cleveland, Ohio *Prof and Dir of Physiology* (1, 1907, 3R, 1909)
- Wiggers, Harold C, Ph D Union Univ, Albany Med College, Dept of Physiology and Pharmacology, Albany 3, N Y *Prof and Chairman of Dept* (1, 1938)
- Wigodsky, Herman S, Ph D, M D Natl Research Council, Committee on Atomic Casualties, Div of Med Sciences, Washington 25, D C *Professional Assoc* (1, 1943)
- Wikler, Abraham, M D USPHS Hospital, Lexington, Ky *Surgeon (R)* (3, 1944)
- Wilber, Charles G, Ph D St Louis Univ, 1402 S Grand Blvd, St Louis 4, Mo *Dir of Biological Labs* (1, 1947)
- Wilde, Walter S, Ph D Tulane Univ School of Medicine, Station 20, New Orleans, La *Assoc Prof of Physiology* (1, 1944)
- Wilder, Russell M, Ph D, M D Mayo Clinic, Rochester, Minn *Prof of Medicine, Mayo Foundation, Univ of Minnesota* (1, 1921, 4R, 1924, 5, 1933)
- Wiley, Frank H, Ph D Federal Security Agency, Food and Drug Admin, Washington 25, D C *Chemist* (2, 1933)
- Wilhelmi, Alfred E, Ph D Yale Univ School of Medicine, 333 Cedar St, New Haven 11, Conn *Assoc Prof of Physiological Chemistry* (2, 1942)

- Wilhelmj, Charles Martel, M D Creighton Univ School of Medicine, Omaha, Neb *Prof of Physiology* (1, 1931)
- Wilkerson, Vernon A , M D , Ph D Med Arts Bldg , 61 K St , N W , Washington, D C *Biochemical Consultant* (2, 1936)
- Williams, Carroll M , Ph D , M D Harvard Univ , Biological Labs , Cambridge, Mass *Asst Prof of Zoology* (1, 1947)
- Williams, Harold H , Ph D Cornell Univ , Savage Hall, Ithaca, N Y *Prof of Biochemistry* (2, 1938, 5, 1936)
- Williams, Horatio B , M D , Sc D Box 893, Greenwich, Conn *Dalton Prof Emeritus of Physiology, Columbia Univ* (1, 1912)
- Williams, J W , Ph D Univ of Wisconsin, Chemistry Bldg , Madison *Prof of Chemistry* (2, 1944)
- Williams, Ray D , M S , M D 6834 Waterman St , St Louis, Mo *Asst Prof of Clin Medicine, Washington Univ* (5, 1941)
- Williams, Robert Hardin, M D Univ of Washington, Dept of Medicine, Seattle *Prof and Exec Officer* (4, 1940)
- Williams, Robert R , D Sc 297 Summit Ave , Summit, N J *Dir of Grants, Research Corp* (2, 1919, 5, 1941)
- Williams, Roger J , Ph.D Univ of Texas, Dept of Chemistry, Austin *Prof of Chemistry, Dir of Biochemical Inst* (2, 1931)
- Williams, W Lane, Ph D Univ of Minnesota Med School, Minneapolis 14 *Assoc Prof of Anatomy* (1, 4, 1947)
- Wills, J H , Ph D Med Div , Pharmacology Section, Army Chemical Center, Md (1, 1943)
- Wilson, Armine T Alfred I DuPont Inst , Wilmington 99, Del (6, 1949)
- Wilson, David Wright, Ph D Univ of Pennsylvania Med School, Philadelphia *Benjamin Rush Prof of Physiological Chemistry* (1, 1915, 2, 1915)
- Wilson, Eva D , Ph D 256 E Irvin Ave , State College, Pa (5, 1947)
- Wilson, Frank N , M D Univ Hospital, Ann Arbor, Mich *Prof of Medicine, Univ of Michigan* (4, 1925)
- Wilson, J Walter, Ph D Brown Univ , Dept of Biology, Providence 12, R I *Chairman of Dept of Biology, F L Day Prof of Biology* (1, 1949)
- Wilson, John W , Ph D Wright-Patterson Air Force, Aero-Med Lab , Dayton, Ohio *Research Physiologist* (1, 1948)
- Wilson, Karl M , M D Univ of Rochester School of Medicine, Rochester, N Y *Prof of Obstetrics and Gynecology* (4, 1927)
- Wilson, P W , Ph D Univ of Wisconsin, Dept of Agricultural Bacteriology, Madison *Prof in Agricultural Bacteriology* (2, 1939)
- Wilson, Robert H , Ph D U S Dept of Agriculture, Western Regional Research Lab , 800 Buchanan St , Albany, Calif *Pharmacologist* (3, 1937)
- Winder, Claude V , Sc D Parke Davis and Co , Detroit, Mich *Research Pharmacologist* (1, 1938, 3, 1948)
- Windle, William Frederick, Ph D Univ of Pennsylvania Med School, Philadelphia *Prof and Chairman of Dept of Anatomy* (1, 1937)
- Winkenwerder, Walter LaF , M D 1014 St Paul St , Baltimore, Md *Assoc in Medicine, Johns Hopkins Med School* (6, 1938)
- Winnick, Theodore, Ph D Univ of Iowa Med School, Iowa City *Assoc Prof of Biochemistry* (2, 1946)
- Winter, Charles A , Ph D Merck Inst for Therapeutic Research, Rahway, N J *Research Assoc* (1, 1940)
- Winter, Irwin Clinton, Ph D , M D G D Searle and Co , P O Box 5110, Chicago 80, Ill *Dir of Clin Research* (3, 1941)
- Winternutz, M C , M D Yale Univ School of Medicine, New Haven, Conn *Anthony N Brady Prof of Pathology* (4, 1913)
- Winters, Jet C , Ph D Univ of Texas, Austin *Prof of Home Economics* (5, 1933)
- Wintersteiner, Oskar, Ph D Squibb Inst for Med Research, New Brunswick, N J *Member, Head, Div of Organic Chemistry* (2, 1930)
- Wintrobe, Maxwell Myer, M D , Ph D Salt Lake County General Hospital, Dept of Internal Medicine, 2033 S State St , Salt Lake City 5, Utah *Prof and Head* (4, 1940)
- Winzler, Richard J , Ph D Univ of Southern California Med School, Dept of Biochemistry, Los Angeles 7 *Assoc Prof of Biochemistry* (2, 1946)
- Wiseman, Bruce Kenneth, M D Ohio State Univ , Kinsman Hall, Columbus *Prof and Chairman of Dept of Medicine, Asst Dir of Med Research* (4, 1932)
- Wislocki, George B , M D Harvard Univ Med School, 25 Shattuck St , Boston, Mass *Parkman Prof of Anatomy* (1, 1924)
- Wissler, Robert W , M D , Ph D Albert Merritt Billings Hospital, 950 E 59th St , Chicago 37, Ill *Asst Prof of Pathology, Univ of Chicago* (4, 1949)
- Witebsky, Ernest, M D Buffalo General Hospital, 100 High St , Buffalo, N Y *Prof and Head of Dept of Bacteriology and Immunology* (6, 1935)
- Wittich, Fred W , M D 401 LaSalle Med Bldg , Minneapolis 2, Minn *Sec -Treas of American College of Allergists, Chairman of Exec Commit-*

- tee, *International Assoc of Allergists* (6, 1944)
- Wolbach, S Burt**, M D Children's Hospital, Boston, Mass *Shattuck Prof Emeritus of Pathological Anatomy, Harvard Med School, Dir of Nutritional Research, Children's Hospital* (4, prior to 1920)
- Wolf, Abner**, M D Columbia Univ College of Physicians and Surgeons, New York City 32 *Assoc Prof of Neuropathology* (4, 1948)
- Wolf, Arnold Veryl**, Ph D Union Univ, Albany Med College, Albany, N Y *Assoc Prof of Physiology and Pharmacology* (1, 1946)
- Wolf, Stewart**, M D Cornell Univ Med College, New York City *Asst Prof of Medicine* (1, 1948)
- Wolff, Harold G**, M D, M A New York Hospital, 525 E 68th St, New York City *Assoc Prof of Medicine, Cornell Univ Med College, Assoc Attending Physician, New York Hospital* (1, 1930, 3, 1942)
- Wolff, William A**, Ph D Wake Forest College, Bowman Gray School of Medicine, Winston-Salem 7, N C *Asst Prof of Biochemistry* (2, 1947)
- Womack, Madelyn**, Ph D U S Dept of Agriculture, Agricultural Research Admin, Foods and Nutrition Div, Washington 25, D C *Biochemist* (5, 1948)
- Wood, Earl H**, Ph D, M D Mayo Aero-Med Unit, Mayo Foundation, Rochester, Minn *Assoc Prof of Physiology, Grad School, Univ of Minnesota, Consultant in Physiology, Mayo Clinic* (1, 1943, 3, 1948)
- Wood, Harland G**, Ph D Western Reserve Univ, Dept of Biochemistry, Cleveland 6, Ohio *Prof of Biochemistry* (2, 1944)
- Wood, John L**, Ph D Univ of Tennessee School of Biological Sciences, 875 Monroe Ave, Memphis 3 *Assoc Prof of Chemistry* (2, 1947)
- Woodbury, Robert A**, Ph D, M D Univ of Tennessee, Dept of Pharmacology, Memphis *Prof of Pharmacology* (1, 1936, 3, 1941)
- Woods, Alan C**, M D Johns Hopkins Hospital, Wilmer Ophthalmological Inst, Baltimore, Md *Dir of Inst and Ophthalmologist-in-Chief, Acting Prof of Ophthalmology, Johns Hopkins Univ* (6, 1918)
- Woods, Ella**, Ph D Univ of Idaho, Moscow *Home Economist, Exper Station* (2, 1925, 5, 1933)
- Woods, Lauren A**, M D, Ph D Univ of Michigan, Dept of Pharmacology, Ann Arbor *Instructor* (3, 1949)
- Woodward, Alvalyn E**, Ph D Univ of Michigan, Ann Arbor *Asst Prof of Zoology* (1, 1932)
- Woodyatt, Rollin T**, M D 237 E Delaware Place, Chicago, Ill *Prof of Medicine, Rush Med College, Univ of Chicago* (2, 1912)
- Wooley, Jerald G** Natl Insts of Health, Exper Biology and Medicine Inst, Bethesda, Md (6, 1949)
- Woolley, D Wayne**, Ph D Rockefeller Inst for Med Research, 66th St and York Ave, New York City *Member* (2, 1946, 5, 1941)
- Woolpert, Oram C**, M D, Ph D Camp Detrick, Frederick, Md *Tech Dir of Biological Div, Chemical Corps* (6, 1947)
- Woolsey, Clinton N**, M D Univ of Wisconsin, Service Memorial Insts, Madison *Charles Sumner Slichter Research Prof of Neurophysiology* (1, 1938)
- Wortis, S Bernard**, M D New York Univ College of Medicine, Dept of Psychiatry, New York City 16 *Prof and Chairman of Dept of Psychiatry, Dir of Psychiatric Div of Bellevue Hospital* (1, 1947)
- Wright, Angus**, M D Univ of Southern California Med School, 657 S Westlake Ave, Los Angeles *Pathologist, California Hospital* (4, 1935)
- Wright, Arthur W**, M D Albany Med College, New Scotland Ave, Albany, N Y *Prof of Pathology and Bacteriology* (4, 1941)
- Wright, Charles Ingham**, Ph D Natl Insts of Health, Bethesda, Md *Sr Pharmacologist, USPHS* (1, 1935, 3, 1936)
- Wright, George G**, Ph D Camp Detrick, Frederick, Md *Chief, Special Procedures Branch, S-Div* (6, 1943)
- Wright, Harold N**, Ph D Univ of Minnesota, Minneapolis *Assoc Prof of Pharmacology* (3, 1933)
- Wright, Lemuel D**, Ph D Sharp and Dohme, Inc, Med Research Div, Glenolden, Pa, *Dir of Nutritional Research* (2, 1946, 5, 1946)
- Wright, Sydney L**, Ph D Endsmeet Farm, Wyncote, Pa (2, 1933)
- Wulff, V J**, Ph D Univ of Illinois, Dept of Zoology and Physiology, Urbana *Asst Prof of Physiology, Special Research Asst* (1, 1949)
- Wyckoff, Ralph W G**, Ph D USPHS, Natl Insts of Health, Bethesda, Md *Sr Scientist* (6, 1940)
- Wyman, Jeffries, Jr**, Ph D Harvard Univ, Biological Labs, Cambridge, Mass *Assoc Prof of Zoology* (1, 1928)
- Wyman, Leland C**, Ph D Boston Univ, College of Liberal Arts, 675 Commonwealth Ave, Boston, Mass *Prof of Biology* (1, 1927)
- Wynne, Arthur M**, Ph D Univ of Toronto, Dept of Biochemistry, Toronto, Ontario, Canada *Prof of Biochemistry* (2, 1940)
- Yonkman, Frederick F**, Ph D, M D Ciba Pharmaceutical Products, Inc, Summit, N J *Dir of Research at Ciba, Lecturer in Pharmacology, Columbia Univ College of Physicians and Surgeons* (3, 1931)
- Youmans, John B**, M D Univ of Illinois, Chicago, Ill *Dean and Prof of Medicine, College of Medicine, Med Dir of Research and Educational Hospitals* (5, 1948)

- Youmans, William Barton, Ph D , M D Univ of Oregon Med School, Portland *Prof of Physiology* (1, 1939, 3, 1949)
- Young, A G , Ph D , M D 520 Commonwealth Ave , Boston, Mass *Asst Prof of Therapeutics, Boston Univ School of Medicine, Med Dir of Corey Hill Hospital, Brookline* (3, 1925)
- Young, E G , Ph D Dalhousie Univ , Halifax, N S , Canada *Prof of Biochemistry* (2, 1925)
- Youngburg, Guy E , Ph D Route 2, Box 268, Mesa, Ariz (2, 1927)
- Yuile, Charles L , M D , C M Univ of Rochester School of Medicine and Dentistry, Rochester, N Y *Assoc Prof of Pathology* (4, 1941)
- Zarrow, M X , Ph D Purdue Univ , Dept of Biological Sciences, Lafayette, Ind (1, 1949)
- Zechmeister, L , Dr Ing California Inst of Technology, Pasadena *Prof of Organic Chemistry* (2, 1941)
- Zeckwer, Isolde T , M D Univ of Pennsylvania School of Medicine, Philadelphia *Assoc Prof of Pathology* (1, 1934, 4, 1927)
- Zeidman, Irving, M D Univ of Pennsylvania School of Medicine, Dept of Pathology, Philadelphia *Instructor* (4, 1949)
- Zeldis, Louis J , M D Brookhaven Natl Lab , Med Dept , Upton, Long Island, N Y *Pathologist, Div of Pathology and Brookhaven Natl Lab Hospital* (4, 1945)
- Zilversmit, D B , Ph D Univ of Tennessee, Dept of Physiology, Memphis 3 *Instructor* (1, 1949)
- Zimmerman, Harry M , M D Montefiore Hospital, Gun Hill Rd , New York City 67 (4, 1933)
- Zirkle, Raymond E , Ph D Univ of Chicago, Chicago, Ill *Prof of Botany and Dir of Inst of Radiobiology and Biophysics* (1, 1948)
- Zittle, Charles A , Ph D U S Dept of Agriculture, Eastern Regional Research Lab , Philadelphia 18, Pa *Chemist, Protein Div* (2, 1946)
- Zucker, Marjorie B , Ph D New York Univ School of Dentistry, Dept of Physiology , 209 E 23rd St , New York City 10 (1, 1947)
- Zweifach, Benjamin W , Ph D New York Hospital and Cornell Univ Med College, Dept of Medicine, 525 E 68th St , New York City 21 *Asst Prof of Physiology* (1, 1945)
- Zwemer, Raymund L , Ph D 5003 Battery Lane, Bethesda 14, Md *Exec Sec , Natl Academy of Sciences and Natl Research Council* (1, 1930)

SUMMARY OF MEMBERSHIP

The American Physiological Society	1155
American Society of Biological Chemists	826
American Society for Pharmacology and Experimental Therapeutics	410
The American Society for Experimental Pathology	333
American Institute of Nutrition	347
The American Association of Immunologists	375
Total membership of Federation	3446

DECEASED MEMBERS

Addis, Thomas (1, 1922) June 4, 1949	Michaelis, Leonor (2, 1929) October 9, 1949
Baxter, J G (2, 1946) April 18, 1949	Petroff, S A (6, 1926) November 26, 1948
Becker, Theodore J (3, 1944) August, 1947	Porter, W T (1, 1891) February 16, 1949
Bookman, Samuel (2, 1912) October 8, 1946	Renshaw, Birdsey (1, 1941) November 23, 1948
Brewer, George (1, 1937) June 13, 1949	Ries, Fred A (1, 1933) August 1949
Brooks, Sumner C (1, 1923) April, 1948	Schnedorf, Jerome J (1, 1941) December 26 1948
Cameron, A T (2, 1914) September 25, 1947	Sinclair, R Gordon (2, 1931) August 17, 1949
Dann, W J (2, 1937, 5, 1938) December 5, 1948	Soley, Mayo (1, 1943) June 21, 1949
Fraser, Alexander MacLeod (3, 1939) 1949	Taylor, Alonzo E (6, 1933) May 20, 1949
Krichesky, Boris (1, 1948) August 28, 1949	Tisdall, Frederick F (2, 1922, 5, 1933) April 23, 1949
Krogh, August (1, 1946) September, 1949	West, Randolph (2, 1931) May 20, 1949
McCullagh, D Roy (2, 1932) September 17, 1949	

LIST OF MEMBERS BY LOCATION

Alabama

AUBURN *Alabama Polytechnic Inst* R W Engel, 5, E L Hove, 5, W D Salmon, 2, 5
BIRMINGHAM *Baptist Hosp* A E Casey, 4
Hillman Hosp T D Spies, 3, 4, 5 *Univ of Alabama* R D Baker, 4, J M Bruhn, 1, E B Carmichael, 1, 2, P Hitchcock, 3, J S McLester, 5, J F A McManus, 4, R S Teague, 3, Elizabeth N Todhunter, 5

TRAVEL AWARDS

18th International Physiological Congress

The Executive Committee of the Federation of American Societies for Experimental Biology has authorized the granting of five or more Travel Awards to younger scientists in the physiological field desiring to present papers before the 18th International Physiological Congress in Copenhagen, Denmark, August 15 to 18, 1950. Awards will be in the amount of \$500 each, and will be made to those scientists, not older than 35 years, who submit for presentation the best contributions in physiology, broadly defined, and give the best evidence of creative productivity. Membership in one of the Federated Societies will not influence selection for an award.

Applicants may address letters to Dr. M. O. Lee, Federation Secretary, 2101 Constitution Avenue, Washington 25, D. C., enclosing seven copies of an abstract of the paper proposed for presentation, and seven copies of a curriculum vitae and bibliography. The applicant should also include a list of two to four references, scientists competent to evaluate the applicant's work.

Applications will be received until January 20, 1950.

A Federation Committee, consisting of the Presidents of the six Societies, will select the individuals to receive the travel awards.

EBERBACH

ELECTRONIC STIMULATOR

A compact, self-contained unit which provides a wide range of repeated, controlled, square wave pulses of fixed duration for physiological and pharmacological experiments and demonstrations

8099-D

ELECTRONIC STIMULATOR, Eberbach A compact, self-contained unit which provides a wide range of repeated, controlled, square wave pulses of fixed duration for physiological and pharmacological experiments and demonstrations. Offered in two executions, similar in appearance but with different pulse duration, pulse amplitude, and maximum output voltage. A control knob, with reference dial graduated from 0 to 10, provides for varying the output voltage from zero to maximum. The pulse duration and voltage amplitude are independent of the repetition frequency, but the amplitude changes with the resistance of the terminal load and the setting of the output control.

Model MV-1 With pulse duration of 1 millisecond, which duration has been found useful for testing nerve reactions. Selector switch, with eleven points, provides the following pulses per second: 0.25, 0.5, 1, 2, 4, 8, 16, 32, 64, 128, and 256. Peak output, no load, is 200 volts, which drops to 155 volts with terminal load of 10,000 ohms, to 120 volts with 5000 ohms, and to 55 volts with 1000 ohms.

Model MV-5 With pulse duration of 5 milliseconds, which duration has been found essential for muscle tissue reactions. Selector switch with ten points provides the following pulses per second: 0.25, 0.5, 1, 2, 4, 8, 16, 32, 64, and 128. Peak output, no load, is 240 volts, which drops to 180 volts with terminal load of 10,000 ohms, to 150 volts with 5000 ohms, and to 65 volts with 1000 ohms.

A multi-vibrator type electronic circuit is employed to generate the square wave pulse, which is free from transients and reversal of polarity. The circuit includes Electronic Tubes 6J5, 6SN7GT, and 5Y3GT. The control panel, in addition to the selector switch for setting the pulse frequency and knob for output voltage control, is supplied with neon glow lamp which flashes in synchronism with output pulses, stand-by output switch, twin binding posts, and on-off switch.

Complete in metal case with black finish and anodized aluminum panel, 9 inches wide × 6 inches high × 5 inches deep.

8099 C Electronic Stimulator Eberbach Model MV-1 as above described, with pulse duration of 1 millisecond for testing nerve reactions. Power consumption, 25 watts. Complete with 8 ft. connecting cord and plug for use on 115 volts 50 or 60 cycles a.c. 91 00
Net weight 6 lbs. Shipping weight 11 lbs. Code Word Meurq

8099-D Ditto Model MV-5 with pulse duration of 5 milliseconds, for muscle tissue reactions. Complete with 8 ft. connecting cord and plug for use on 115 volts, 50 or 60 cycles, a.c. 91 00
Net weight 6 lbs. Shipping weight 11 lbs. Code Word Meurq

FEDERATION PROCEEDINGS is published quarterly by the Federation of American Societies for Experimental Biology. The *March* issue consists of the program (Part II) of the Annual Meeting of the Federation, and the Abstracts (Part I) of the papers presented at the scientific sessions. The program includes an author index. The abstracts are arranged alphabetically according to the first author and segregated as to Societies. The *June* and *September* issues contain symposia and other special papers presented at Federation meetings as selected by the Editorial Board. The *December* issue contains the membership list and other matters pertinent to the Constituent Societies of the Federation.

Price Schedule

The subscription price is \$4.50 (\$5.25 foreign) payable in advance. Single issues may be purchased, if ordered in advance, at the following prices: No. 1 (Part I March, Abstracts), \$3.00; No. 1 (Part II, March Program), 50¢; Nos. 2 and 3 (June and September), \$1.50 an issue; No. 4 (December), \$2.00. Subscriptions and orders should be sent to the Federation of American Societies for Experimental Biology, 2101 Constitution Ave., Washington 25, D. C.

Entered as second-class matter March 16, 1942 at the Post Office at Baltimore, Maryland under the Act of August 24, 1912

NOW available for laboratory investigations MY-B-DEN

(ADENOSINE-5-PHOSPHORIC ACID, BISCHOFF)

The potentialities of this unique biochemical—prepared by Ernst Bischoff Company, Inc.—can now be more thoroughly investigated. Our newly developed method permits increased production of exceptionally pure adenosine-5-phosphoric acid and insures adequate supplies for pharmacological study and for further progress in bacteriological and biochemical research.

Adenosine 5 phosphoric acid, a purine nucleotide present in coenzymes I and II and flavin dinucleotides, is intimately associated with life processes. Also fundamental in phosphorylation reactions, this crucial compound is a vital metabolic link in energy transfer mechanisms like muscular contraction and other enzymic reactions.

Pharmacological reports indicate the applicability of MY-B-DEN to the problems of vascular disturbances, cardiovascular malfunction and the degenerative diseases. Its value in the treatment of these disorders is being elucidated by further pharmacological research projects.

Summary of Data on a Typical Preparation of MY-B-DEN
(Adenosine 5 Phosphoric Acid, Bischoff)

Source—Yeast fermentation procedures

How Supplied—Crystalline free acid

Formula— $C_{10}H_{14}N_5O_7P \cdot H_2O$

Purity—99.5%, based on adenine, ribose and phosphorus content

Molar Ratio—Adenine : ribose : phosphorus = 1.00 : 1.01 : 1.01

Position of phosphorus—Unequivocally on ribose in 5 position

Inorganic phosphorus—None present

Complete analytical data, pertaining specifically to the individual MY-B-DEN preparation released, accompanies each shipment.

The related compounds available are adenosine and guanosine.

In the Treatment of URINARY TRACT INFECTIONS

Experience shows the
value of this highly
purified form of
Streptomycin

STREPTOMYCIN Calcium Chloride Complex Merck is a potent antibacterial agent which is effective in the treatment of urinary tract infections due to a large group of susceptible organisms

It is rapidly absorbed into the blood stream, and 60 to 80 per cent is excreted by the kidneys in twenty-four hours. High concentrations can be obtained in the urine, far above those to which the organisms common in urinary tract infections usually are susceptible *in vitro*. The uniformly high potency of Streptomycin Calcium Chloride Complex Merck, and its high degree of purity, give this form of streptomycin definite advantages in urinary tract infection therapy.

It is supplied in sterile, rubber-stoppered, aluminum-capped 20 cc. vials containing the equivalent of 1 Gm. of Streptomycin Base and 50 cc. vials containing the equivalent of 5 Gm. of Streptomycin Base.

FRACTIONATION PROBLEMS?

here's help for you . . .

THIS tireless servant in your laboratory will automatically collect any number (up to 200) of rigidly controlled samples of predetermined fluid volumes. Each collected sample may comprise any number of drops from one to four hundred. As each separate sampling is completed, the carriage automatically advances to repeat identical collections consecutively until the whole fractionation has been made.

All you have to do is to set it up for the conditions of the chosen experiment, short or long, and then leave it alone. The machine will plod along without attention hour after hour, all day (and night) long. When the job's done, it will shut itself off.

The Technicon Fraction Collector has been thoroughly tested in actual laboratory installations, where it has proven invaluable to busy research staffs. We shall be happy to send you details.

Ref. Chromatography of Amino Acids on Starch Columns—
W. H. Stein and S. Moore, *Jrnl Biol Chem* 176, 337, (1948)

saves time and labor

relieves laboratory staff of the fretful and time-consuming chore of fraction-cutting; releases workers for other duties.

triples work output

you can run it twenty-four hours a day, continuously, to triple fractionation output as compared with an 8 hour laboratory day.

gives greater resolution

by collecting a large number of small fractions, rather than a few gross ones, you'll get more data from a given fractionation, e.g. a chromatogram, or a fractional distillation.

assures accuracy

because the possibility of human error is automatically ruled out. Now fraction-collection becomes a straightforward mechanical procedure.

Check these features before you buy a centrifuge—

- ✓ **A compact, lightweight unit**—can be carried easily, will fit in a small refrigerator when centrifuging in the cold is required
- ✓ **Provides a faster sedimentation rate and more complete sedimentation** with finely dispersed particles by utilizing the angle principle of suspending the tubes at a fixed 52° angle
- ✓ **Can be used for micro and semi-micro work** by substituting the proper shields and tubes
- ✓ **Head is precision-machined** for accurate balance
- ✓ **Rheostat has an “off” position** and allows for continuous speed control
- ✓ **Vibration is absorbed** by rubber suction feet which keep the unit from creeping, even on a glass surface
- ✓ **Maximum speed, fully loaded**—4000 RPM on AC, 4500 RPM on DC
- ✓ **Finished in attractive gray hammertone**

BOOKS YOU SHOULD NOT OVERLOOK

H O B E R

Physical Chemistry of Cells and Tissues

Presents material of major importance to teachers, students and workers in physical chemistry, medical and biological physiology. The thesis is physiology as a branch of physicochemical science dealing with life as an integrated series of physical phenomena. Emphasis is given to new developments in submicroscopic structures. The book offers a new approach to how, in cell

life, chemical energy is transformed into mechanical or osmotic work. Some of the contents: principles of physical chemistry, properties, architectural and functional significance in living matter of the large molecules, respiration of cells and tissues, passive penetration etc.

W I N T O N and B A Y L I S S

Human Physiology (3rd Edition)

Students in medicine and dentistry will find in this very popular textbook a thorough presentation of the relationships between pathology and physiology, and of physiological experimental evidence. All chapters have been revised and a large number of new illustrations added. Each section was written by a colleague

with special knowledge and experience. A particularly valuable feature. Subject matter includes the circulation, autonomic nervous system and chemical transmission at nerve endings, the sense organs, ductless glands, and many others.

248 Illus., 592 Pages, \$7 00 (*1948*)

mass demonstration in the auditorium

The projectionist can follow a specimen through a progressive series of ever closer localizations, from its gross aspect to its ultimate microscopic demonstration under oil immersion

for example in

tumor study

The auxiliary Scopicon dark chamber "round-table" affords superb facility for small-group study. Here the projected image is cast upon a platen within a light tight chamber, with separate light-excluding viewing hoods for each observer. Any number up to ten may share in conference, which can be conducted in a normally lighted room. A pointer at each port permits any observer to indicate areas of interest to all the others for discussion.

... and for
small-group
"round-tables"
in a normally
lighted room

The 64,000 lumen intensity of the Scopicon high-pressure mercury lamp permits auditorium demonstration of tissue sections even under oil-immersed microscope objectives. In projected images six feet or more across, every detail of the cellular structure stands out clearly, due to the pinpoint character of the 1 mm square (approx.) focal spot employed. The Scopicon light is steady and flickerless; its brilliant white color exhibits biological stains to the greatest advantage. May we send you the brochure describing this versatile instrument?

How to select an "all-purpose" antiseptic

The ideal antiseptic:

Much is demanded of a good antiseptic. It must meet exacting requirements under the varying circumstances of clinical use.

Is effective against **M**any types of pathogenic organisms

Is effective **E** against a high concentration of the organisms.

Retains its germicidal activity in high dilution

Maintains its effectiveness for a prolonged period

Has a rapid onset of action

Is compatible with body tissues and fluids

Does not hemolyze red blood cells

Is fungicidal

Is nonirritating to skin and tissues

It is not inactivated in the presence of soap

Has a low incidence of sensitivity

'Merthiolate' (Sodium Ethyl Mercuri Thiosalicylate, Lilly) fulfills the eleven specifications for the ideal antiseptic. It is characterized by its general applicability to all types of clinical antiseptics. Forms of 'Merthiolate' include the tincture, 1:1,000, the solution, 1:1,000, the jelly, 1:1,000, the ointment, 1:1,000, the ophthalmic ointment, 1:5,000, the vaginal suppositories, 1:1,000, and 'Sulfo Merthiolate' (Sodium *p* Ethyl Mercuri Thiophenylsulfonate, Lilly), 1:1,000, Surgical Powder. Preparations of 'Merthiolate' are available from your regular source of medical supplies.

NUMBER 2

NOTES ON THE DETROIT CONVENTION OF THE FEDERATION

April 18 to 22, 1949

The thirty-third annual meeting of the Federation of American Societies for Experimental Biology was held at Detroit, Michigan, April 18 to 22, 1949. Headquarters hotels were the Book-Cadillac for three Societies (Biochemistry, Pathology and Immunology) and the Statler for three Societies (Physiology, Pharmacology and Nutrition). All of the scientific sessions of the Societies were held in the Masonic Temple, as was also the Joint Session of the Federation on Tuesday evening, April 19. One motion picture session was presented, at the Detroit-Leland Hotel. The Federation 'Mixer' was held Wednesday evening, April 20, at the Hotel Statler.

Dr. Harry P. Smith, President of the American Society for Experimental Pathology, was Chairman of the meeting and presided at the Joint Session. One hundred and thirteen scientific sessions were held at which 1304 papers were read and 170 papers were read by title. Symposia were presented by the American Society of Biological Chemists, the American Society for Pharmacology and Experimental Therapeutics, the American Institute of Nutrition and the American Association of Immunologists.

The total registered attendance was 3517, including guests (wives of members) and exhibitors. As in previous years, the attendance was about equally divided between Society members and non-members.

Forty-four technical exhibits, occupying 60 booths, were shown.

FEDERATION ACTIONS

The following actions of the Federation Executive Committee are of general interest.

1 The plan to hold the 1950 meeting of the Federation in Atlantic City, New Jersey, April 17 to 21, was confirmed.

2 The Federation assessment for the year beginning July 1, 1949, was set at \$3.00 per member of each Society (all members to be in-

cluded, whether retired, honorary or members of more than one Society). The assessment includes subscription to *FEDERATION PROCEEDINGS*.

3 It was decided to permit the sale of reprints of abstracts published in the March 1950 issue of *FEDERATION PROCEEDINGS*; provided orders and payment are sent with the abstracts.

4 The Societies approved in principle the proposal for drafting a Constitution, revision of the By-Laws and incorporation of the Federation, the Constitution and By-Laws to be referred to the Societies for approval.

5 The Executive Committee voted that the form of the listing of members in the December issue of *FEDERATION PROCEEDINGS* be revised and that each entry contain only the following information: name of member, highest earned degree (when applicable both the M.D. and Ph.D. degrees, or, when applicable, the highest earned graduate-school degree and the M.D. degree), mailing address, title of position held (not more than two), and the Society affiliation.

6 The Executive Committee approved the proposal that upon adoption of the new Constitution and By-Laws the Control Committee for *FEDERATION PROCEEDINGS* be replaced by an Editorial Committee composed of the Society Secretaries and the Managing Editor.

7 The American Institute of Nutrition will act as the host Society for the 1950 meeting and will arrange the program of the Joint Session.

INTERNATIONAL CONGRESSES

Two International Congresses of interest to members of the Federation are scheduled for 1949 and 1950.

a) The First International Congress of Biochemistry will be held August 19 to 25, 1949, at Cambridge, England.

b) The 18th International Physiological Congress will be held August 15 to 18, 1950, at Copenhagen, Denmark.

Chairman H. P. SMITH

AMINO ACID METABOLISM IN MUTANT STRAINS OF MICROORGANISMS

E. L. TATUM

From the Department of Biological Sciences, Stanford University

STANFORD, CALIFORNIA

THIS discussion of some aspects of amino acid metabolism in microorganism is necessarily limited in scope. It will deal primarily with metabolic relations which have been found to be of general significance in both higher and lower organisms and with certain new relations, probably also of general significance, which have been suggested by studies with microorganisms. In both instances, the discussion will center around the results obtained with the help of mutant strains.

Mutations which have as biochemical consequences defective biosyntheses of essential cellular constituents, such as vitamins and amino acids, are being produced in steadily increasing numbers of types of microorganisms. These now include representative bacteria, yeasts and fungi.

In order to give some idea of how nutritionally-deficient mutant strains of microorganisms are produced and isolated, a brief summary of various techniques now available is given in table 1. Basically, mutations in a microorganism are produced by exposing the culture to the action of a mutagen, γ -rays, ultra-violet radiation, or chemicals such as mustard-gas. Pure genetic lines of the treated material are derived from single spores with fungi, or from single vegetative cells with bacteria, by growing them on a 'complete' medium which supplies a variety of growth-factors, both known and unknown. A nutritionally deficient mutant among these cultures is detected by its failure to grow in a 'minimal' synthetic medium, and its defective biosynthesis is identified by testing its growth in variously supplemented synthetic media. This method has been used with *Neurospora* (1) and with *E. coli* (2) and other microorganisms. Several less laborious methods for selecting mutants from large popula-

tions have recently been developed. These are also summarized in table 1. All of these modifications are based on the failure of a mutant to metabolize and grow normally without its specific essential supplement. When this supplement is added after a period of incubation, mutant cells of bacteria only then form colonies which at a given time are smaller than those from normal cells (3). Fries has successfully increased the proportion of mutant spores of the mold *Ophrostoma* in mixtures by removing the germinated normal mycelia by filtration (4). With *Ophrostoma* (4) and with *Neurospora* (5) mutants have been visually selected from populations of spores cultured on minimal agar media on the basis that a mutant fails to grow or grows very slowly under these conditions. Even more efficient are methods based on the more rapid death of normal cells due in one case to exhaustion of endogeneous reserves in a minimal medium lacking a growth-factor required by the normal strain (6) and due in the other instance to the growth and consequent sterilization of normal cells in minimal medium containing penicillin (7, 8).

If the B-vitamins and the amino acids are metabolically essential for microorganisms, and if random mutation in nature or in the laboratory results in defective syntheses of these substances, we would expect to find a close correlation between the growth factor requirements of strains as isolated from nature and mutant strains produced experimentally. This expectation is fairly well fulfilled.

The requirements of mutant strains which have now been found in bacteria and fungi do include most of the known water soluble vitamins and the amino acids. This widespread range is summarized most easily by listing those sub-

stances not yet so represented. It can be seen from table 2 that deficiencies in mutant strains of fungi include riboflavin, pantothenic acid,

TABLE 1 TECHNIQUES FOR ISOLATING NUTRITIONAL MUTANTS OF MICROORGANISMS

DESCRIPTION OF METHOD	ORGANISM USED	REFERENCE
Isolation on complete medium, testing on minimal	<i>Neurospora</i>	(1)
Incubated in minimal, later supplemented as desired	<i>E coli</i>	(2)
Incubated in minimal, non-mutants removed by filtration	<i>E coli</i>	(3)
Incubated on minimal, mutants selected by observation	<i>Ophiostoma</i>	(4)
Incubated in minimal, with selective survival of mutants	<i>Ophiostoma</i>	(4)
Incubation in minimal with penicillin, with selective survival of mutants	<i>Neurospora</i>	(5)
	<i>Ophiostoma</i>	(6)
	<i>E coli</i>	(7, 8)

TABLE 2 COMPARISON OF NUTRITIONAL REQUIREMENTS OF MUTANT AND WILD-TYPE STRAINS OF MICROORGANISMS

FILAMENTOUS FUNGI		BACTERIA	
Strains from nature	Mutant strains	Strains from nature	Mutant strains
B-vitamins not required			
B ₂	B ₁₂	Inositol	B ₂
Pantothenic acid	Folic acid	Choline	Inositol
Nicotinic acid			Choline
p - amino benzoic acid			B ₁₂
Choline			Folic acid
B ₁₂			
Folic acid			
Amino acids not required			
?	Alanine	Alanine	Alanine
	Hydroxyproline	Hydroxyproline	Hydroxyproline

nicotinic acid, p-aminobenzoic acid and choline, which are not required by any filamentous fungi yet isolated from nature. So far as is known, folic acid and vitamin B₁₂ are not required either

by fungi from nature or by mutant strains. For the bacteria, inositol is not yet known to be required but all the other vitamins except riboflavin, folic acid, B₁₂ and choline are included in the requirements of mutant strains.

A similar comparison for amino acids suggests that in nature few spontaneously arising amino acid-requiring mutants of non-pathogenic fungi survive. However, mutant strains of fungi have been found with requirements for all the well-established amino acids except alanine and hydroxyproline. The same is true for strains of both classes of bacteria.

There is therefore available a wealth of experimental material in mutant strains of bacteria and fungi. In the strains to be considered, for example, single reactions in the biosyntheses of amino acids are blocked by gene mutations in a more specific manner than possible with enzyme inhibitors. The use of mutant strains as tools in the biochemical analysis of synthetic mechanisms is evident. However, before discussing specific examples of this, I want to mention briefly a phenomenon which has been found fairly frequently in mutant strains requiring amino acids. This phenomenon is one of a specific and often extreme susceptibility to growth inhibitions caused by certain amino acids, usually not the ones required for growth. These inhibitions are important both because they may indicate previously unsuspected interrelations between amino acids, and because they must be taken into account in the interpretation of studies of biosyntheses. To illustrate the diversity of antagonistic amino acid relations in *Neurospora* some examples are shown in table 3. Similar antagonisms have been invoked by Bonner to explain the double requirement of a mutant strain of *Neurospora* for isoleucine and valine (15). In this case an accumulated precursor of isoleucine appears to inhibit the synthesis of valine, and both are therefore required.

I now want to discuss some of the biochemical interrelations which have been found in amino acid metabolism in microorganisms. Three general considerations should be emphasized for this discussion: first, the validity of the viewpoint of comparative biochemistry, that the biochemical processes of microorganisms, higher plants, and animals are fundamentally similar; secondly, the contributions of studies with mutant strains of microorganisms to the analysis of the biochemical steps involved in reactions and relations between amino acids; thirdly, the im-

portance of mutant strains of microorganisms in discovering hitherto unknown reactions and unsuspected amino acid interrelations

Since amino acid metabolism has been most thoroughly studied in mutants of *Neurospora* and of *E. coli*, the examples used in this discussion for the most part will come from work with these two microorganisms

As shown in figure 1, one of the best examples of the essential similarity of amino acid metabolism in different organisms is the synthesis of arginine, in which the same steps of the ornithine cycle are involved in mammals, in *Neurospora* (16), in *Penicillium* (17), and in bacteria (18, 19)

TABLE 3 SOME AMINO-ACID ANTAGONISMS IN *NEUROSPORA*

GROWTH-FACTOR	GROWTH INHIBITOR	REFERENCE
Isoleucine + valine	Excess of either	(9)
Lysine	Arginine	(10)
D- α -amino adipic acid	Arginine, asparagine, glutamic acid	(11)
Glycine or serine	Asparagine	(12)
Methionine or threonine	Excess methionine	(13)
None (reversed by arginine)	Canavanine	(14)
Histidine	'Complete' medium	(5)
Adenine	Indole	(5)

FIG 1

thine cycle are involved in mammals, in *Neurospora* (16), in *Penicillium* (17), and in bacteria (18, 19) Further probable relations of arginine to glutamic acid and to proline are indicated by reactions 1, 2, and 4 One mutant strain of *E. coli* is apparently blocked at step 1 and another at 4, resulting in requirements for glutamic acid or proline, and for proline, respectively (2) A block at reaction 2 in *Penicillium* apparently explains a requirement for proline or for arginine (17)

Another excellent example of the essential similarity in different organisms is in the metab-

olism of the sulfur-containing amino acids As shown in figure 2, the relation of cystathionine to cysteine and methionine first established for higher animals by du Vigneaud and collaborators holds also for *Neurospora* (20) and *E. coli* (21) Some minor differences exist, however In *Neurospora* serine as such seems not to be formed from cystathionine (13) In *E. coli* the reactions leading from methionine to cysteine apparently do not operate in that direction, and this bacterium differs from *Neurospora* in being able to use D-allo-cystathionine as a source of methionine (21)

Investigations with mutant strains of *Neurospora* have also indicated unsuspected relations between homoserine and threonine (13), as pic-

FIG 2

FIG 3

tured diagrammatically in figure 3 Strain 51504 grows with either amino acid A similar relation has been found in mutant strains of *B. subtilis* by Teas (22) An even more surprising relation is suggested by a mutant strain of *Neurospora* with an alternative requirement for isoleucine or threonine (22) These intriguing amino acid interconversions remain to be elucidated

The metabolic relation between lysine and α -amino adipic acid found in the rat by Borsook and collaborators (23) and shown in figure 4, has been found also in *Neurospora* since α -amino adipic acid has recently been shown to be a precursor of lysine for strain 33933 (11)

Although antranilic acid, indole, and tryptophane have for some time been known to be met-

abolically related, convincing evidence that anthranilic acid is a precursor of tryptophane was first obtained with mutant strains of *Neurospora* (24). This is shown in figure 5. The mechanism of the conversion of indole to tryptophane has likewise been analyzed with *Neurospora*, and has been shown to involve a hitherto unsuspected condensation of indole with the amino acid serine (25). There seems to be at least two steps involved in the conversion of anthranilic acid to indole, since two genetically different mutants are unable to carry out this reaction. A clue to the mechanism of this conversion has been given by

FIG 4

FIG 5

Nyc *et al* (26) who have found by isotopic techniques that the carboxyl carbon of anthranilic acid is not present in the formed tryptophane. The conversion of indole to tryptophane has been shown to be an enzymatic reaction involving pyridoxine (27). Recently a mutant strain of *Neurospora* which requires tryptophane and which apparently lacks this enzyme has been described (28). This evidence provides excellent supporting evidence that a gene-enzyme relation is involved in the genetic control of biosynthetic reactions.

An interesting relation between an amino acid and a vitamin is the conversion of tryptophane to nicotinic acid. This relation has been substan-

tiated and clarified with mutant strains of *Neurospora*. As shown in figure 6, some strains of *Neurospora* are known which require either tryptophane or nicotinic acid. This conversion is most readily explained by steps involving kynurenine, the hypothetical compound hydroxykynurenine and the established intermediate 3-hydroxyanthranilic acid. This latter compound is converted to nicotinic acid by strains 40008 and 65001 and by strain Y31881 (29-31). The production of this last intermediate by strain 4540 has been demonstrated by Bonner (31). The evidence obtained with these strains of microorganisms thus lends excellent support to the relation of tryptophane and nicotinic acid suggested first by animal studies. In addition, this conversion has been shown to involve several new

FIG 6

FIG 7

biochemical reactions of considerable general significance.

Another interesting relation which exists both in animals and in microorganisms is that of the interconversion of glycine and serine. Strains of bacteria (18, 19) and of *Neurospora* (12) are known which have alternative requirements for either glycine or serine. The relation of these two amino acids has been demonstrated in higher animals by Shemin (32) and the mechanism illustrated diagrammatically in figure 7 has been recently suggested by Sakami (33). Sakami's evidence, based on the use of marked glycine, suggests that glycine gives rise to formate, which then reacts with another molecule of glycine to form serine. This reaction may be involved in the interconversion of these amino acids in microorganisms. The arrow marked with the two strain numbers on the figure represents the reac-

tion chain leading into this series. There seem to be at least two steps which have been genetically blocked in the synthesis of glycine and serine. Evidence now available suggests that the rat and *Neurospora* may metabolize glycine in somewhat different fashions. Shemin has presented evidence that in the rat glycine is not particularly active in transamination reactions. In *Neurospora*, glycine apparently very readily supplies amino nitrogen for the formation of several other amino acids, including tryptophan, histidine, aspartic acid, and glutamic acid, as indicated by the use of nitrogen labelled glycine with a glycine requiring strain (34).

Some other extremely interesting relations between amino acids have been found which deal with the aromatic compounds phenylalanine, tyrosine, anthranilic acid and para-aminobenzoic acid. The precise mechanisms of these interrelations remain to be investigated. As diagrammatically represented in figure 8, mutant strains with re-

FIG 8

quirements for each one of the indicated aromatic compounds are known in *E. coli* (18, 19, 35) and in *Neurospora* (24, 36, 37). In *E. coli* recovery experiments have indicated that phenylalanine and tyrosine are synthesized independently, perhaps from a common precursor (35). The synthesis of all four compounds from a common precursor (x) is suggested by the existence of a mutant strain of *Neurospora*, Y7655, which requires all four substances (36) and by the existence of similar multiple-requiring mutants in *E. coli* (19). The relations existing in these mutant strains provide extremely interesting possibilities for further biochemical investigations of the biosynthesis of aromatic compounds.

Shemin (32) has suggested that the non-essential amino acids may be synthesized in the rat by amino acid interconversions rather than by amination of their keto acid analogues. Recent investigations with *Neurospora* have suggested that the keto acid of at least one essential ali-

phatic amino acid may not be directly involved in its biosynthesis. Working with a mutant strain of *Neurospora* which requires isoleucine and valine (9, 15) E. A. Adelberg, in our laboratory, has recently isolated and identified a new intermediate in the biosynthesis of isoleucine. The structure of this compound and a tentative suggestion of its part in the synthesis of isoleucine are indicated in figure 9. The keto acid analogue of isoleucine is perhaps only indirectly related to the biosynthesis of isoleucine in microorganisms. The evidence for this includes the inactivity of the keto acid in releasing the valine inhibition of growth of wild-type *E. coli*. In addition, some mutant strains of bacteria have been found capable of using the dihydroxy or the keto-acid analogue instead of isoleucine, while other mutant strains can use only the dihydroxy analogue in place of isoleucine. This evidence apparently provides a new clue to the mechanism of synthesis of aliphatic α -amino acids.

FIG 9

As mentioned earlier, there is now a considerable body of evidence suggesting that many amino acids may be synthesized by interconversions rather than directly from their keto acid analogues. In addition, evidence is now available that some keto acids are biologically inactive in certain microorganisms. These two lines of evidence cast some doubt on the general significance of direct amination reactions as terminal steps in the bio-syntheses of certain amino acids in microorganisms. Some examples are summarized in table 4. In the first group of examples listed, the most probable syntheses are by way of mechanisms other than amination of the keto acids, perhaps those indicated in the last column of the table. In several instances the keto acids have been found to be inactive for mutant strains of microorganisms. It might be concluded that perhaps the only amino acids which are formed *de novo* by direct amination or transamination are those directly related to known intermediates in

carbohydrate metabolism, notably alanine, aspartic acid and glutamic acid

Some of the known amino acid relations which have been found to be common to both mi-

TABLE 4 KETO-ACID AND AMINO ACID RELATIONS IN MUTANT STRAINS OF MICROORGANISMS

AMINO ACID	ACTIVITY OF KETO-ACID ANALOGUE	PROBABLE SYNTHESIS FROM
Arginine	?	Citrulline (16)
Lysine	?	α -aminoadipic acid (11)

Ornithine \rightarrow citrulline \rightarrow arginine
 cystathionine \rightleftharpoons homocysteine + [serine]
 cystathionine \rightleftharpoons homoserine + cysteine
 glycine \rightleftharpoons serine
 α -aminoadipic acid \rightleftharpoons lysine
 tryptophane \rightarrow nicotinic acid
 tryptophane \rightarrow kynurenine

TABLE 6 REACTIONS AND INTERRELATIONS ESTABLISHED WITH MICROORGANISMS

indole + serine \rightarrow tryptophane
 threonine \rightleftharpoons homoserine
 anthranilic acid ($-\text{CO}_2 + ?$) \rightarrow indole
 kynurenine \rightarrow 3-hydroxyanthranilic acid
 3-hydroxyanthranilic acid \rightarrow nicotinic acid
 α, β , dihydroxy, β -ethyl-butyrlic acid \rightarrow isoleucine

croorganisms and animals are summarized in table 5. These reactions, which have already been discussed, include those of the ornithine cycle, the relation of cystathionine to methionine and cysteine, the interconversion of glycine and serine, the relation of alpha-aminoadipic acid to lysine,

and the conversion of tryptophane to nicotinic acid, and to kynurenine

As the result of examinations of the mechanisms of these and other biosynthetic reactions with mutant strains of microorganisms, a number of new reactions and relations have been established. These include the reactions summarized in table 6. The involvement of serine in the synthesis of tryptophane has been discussed. The relationship of threonine to homoserine suggested by studies with microorganisms remains to be elucidated. Similarly, the exact steps in the conversion of anthranilic acid to indole are as yet unknown. The essential outline of the biochemical steps involved in the conversion of kynurenine to 3-hydroxyanthranilic acid, and of this compound to nicotinic acid has been suggested. Finally, a role of α, β -dihydroxy- β -ethylbutyric acid in the biosynthesis of isoleucine has been fairly adequately established by studies with microorganisms.

It may be expected that future investigations with microorganisms, particularly with mutant strains, will reveal other new and unsuspected relations between amino acids, and that these strains will prove highly useful tools for the elucidation of the mechanisms of reactions involved in the biosyntheses of these amino acids. It may also be anticipated that further studies correlating enzyme activity with gene mutation will add additional information regarding the role of the gene and of gene mutations in determining enzyme specificity. The first clear-cut example of this relationship in *Neurospora* is the enzyme involved in tryptophane synthesis from indole and serine. Information is now available which should permit the extension of this analysis of gene-enzyme relations to other biosyntheses. These include the syntheses of the amino acids arginine, proline, glycine, and serine. It may be expected that other reactions will become available for such studies as the precise mechanisms of the biosyntheses of other amino acids are established.

In summary, we have discussed various aspects of amino acid metabolism in the examination of which microorganisms have been of primary value. Judging from past experience we may anticipate that additional discoveries coming from studies from microorganisms will be of general metabolic significance. The principles of comparative biochemistry thus adequately justify the use of microorganisms in investigations of amino acid

metabolism In these investigations mutant strains of microorganisms should prove of significant value in future developments

VIRAL MULTIPLICATION

FRANK L. HORSFALL, JR.

From the Hospital of The Rockefeller Institute for Medical Research

NEW YORK CITY

WHEN a virus and a susceptible cell come together, there occurs an increase in the amount of the virus. An increase in the concentration of a virus has not been obtained as yet in cell-free media nor in the absence of living cells. It is now well established that viruses are discrete particles with definite morphology which can be visualized with the electron microscope (1). An increase in viral concentration is associated with an increase in the number of viral particles of like amount, there is a close correlation between the number of particles and the number of infective units (2).

The increase in the amount of virus which occurs in the presence of susceptible cells is generally considered to result from viral multiplication. The validity of this concept was indicated by the early classic work of Woodruff and Goodpasture (3). Apparently, viruses do not carry out demonstrable metabolic activities (4, 5). Moreover, they have not been shown to contain known enzyme proteins (2). If this is true, it seems important to inquire: How do viruses undergo multiplication, where do they acquire the substance and energy necessary for their synthesis, what orients and directs the process? Most workers now think that during their multiplication viruses derive the needed mass and energy from the host cell. But the directional, orienting influence appears to derive from the virus itself even though it may operate through the indispensable partner, the host cell.

Because viruses apparently are multiplied within the host cell and give little evidence of their presence until they burst forth, it is not simple to learn what goes on. Studies with bacteriophages, which are often termed bacterial viruses, have yielded important information. The development by Burnet (6) of a method for measuring the yield of virus from individual bacteria and the development of the one-step growth experiment and other techniques by Ellis and Delbrück (7) made possible close analysis of the multiplication of bacterial viruses. The process is considered as a series of step-wise events.

Chance collisions bring the viral particle and bacterial cell together. Attractive forces lead to adsorption of virus at the surface of the cell. One viral particle is all that is required to initiate multiplication, but the cell can adsorb a number of particles equal to the number it can produce (8). Adsorption is rapid and may be essentially completed in a few minutes (9). Adsorption co-factors such as univalent cations (10), tryptophane (11) or calcium may be required. The virus enters the cell, which then rapidly becomes altered with the result that other viruses usually cannot multiply within it (12). At this point mysterious events take over. The virus seems, in effect, to have disappeared as is indicated by the experiments of Cohen and Anderson (13) and Foster (14). This puzzling state, which is termed the latent or silent period, continues for 13 to 40 minutes, depending on the virus employed, when suddenly the virus reappears, i.e., bursts from the cell in large numbers (8). As Delbrück (15) has shown, one viral particle leads to the synthesis of 100 to 400 new viral particles in this short interval. Multiplication has occurred, of this there is no doubt, but it happened during the latent period and its stages were unobserved. The results of the numerous elegant experiments which have been carried out provide data about the kinetics of the interaction between bacterial virus and cell, the preliminary events and the final results, but shed no clear light upon the real problem: the biochemical mechanism of viral multiplication.

Results which are closely analogous have been obtained with certain animal viruses, especially the influenza group and mumps. Adsorption by susceptible cells (16-18), the probable nature of certain cell receptors (19), the duration of the latent period and the approximate number of viral particles liberated (20) have been demonstrated. The only striking difference from the bacterial viruses appears in the length of the latent period. With influenza viruses, Henle, Henle and Rosenberg (20) found that this period

is of the order of 6 to 9 hours, with mumps virus it appears to be considerably longer (21)

The riddle of multiplication has puzzled many workers since viruses first were recognized. Various hypotheses have been proposed. With the larger viruses, the psittacosis group as example, the life cycle hypothesis has its proponents, and changes in the size, staining properties and number of intra-cellular viral particles have been correlated with multiplication of the agents (22, 23). Growth and division, as with bacteria, is a possibility but many facts do not fit such a theory. Self-reduplication or autocatalytic processes have been invoked, chiefly since the crystallization of some plant viruses was achieved (24). These processes are hardly less mysterious than viral multiplication itself and do not provide a satisfactory solution to the problem (25). A virus precursor hypothesis has been put forward. According to this view (26) the precursor is present in the cell before infection and is transformed to virus by an autocatalytic process. Another suggested mechanism is the template hypothesis: virus is synthesized by the cell in conformity with the models (the templates) it presents to the intracellular enzymes (25).

The phenomenon of viral interference, perhaps more than any other, has called forth a turn in current ideas. Infection with one virus often precludes infection with another, one virus may act as inhibitor of the multiplication of another. The characteristics of the reaction (27, 28) are consistent with the idea that it is competitive. That it is not dependent upon competition for cell receptors appears established (27, 29), as is the fact that it can be obtained with inactivated virus (30, 31). Taken together, the existing data suggest that the competition may be for a metabolic system in the host cell and that both the integrity and availability of this system are essential for viral multiplication.

If all pairs of viruses showed interference, it could be supposed that all required similar metabolic pathways in the host cell. But numerous pairs of viruses do not show interference, some are capable of simultaneous multiplication in a single cell (32, 33). Because competition does not occur in these instances, it seems probable that non-interfering viruses demand different metabolic pathways of the cell. How many pathways for different viruses there may be is not known but in the cells lining the allantoic sac of the chick embryo it appears there are at least three (21, 29).

Studies on interference have raised the possi-

bility that identifiable metabolic steps may be demonstrable. More detailed information concerning cyto-chemical processes would be of value in unravelling their nature. In the absence of adequate information regarding cellular synthetic processes, attempts have been made to find substances which block viral multiplication and act as specific inhibitors. Knowledge of the chemical nature and structural configuration of such substances may help in identifying the metabolic steps which they block.

Certain acridine compounds have been found to inhibit the multiplication of certain bacterial viruses (34, 14) as well as influenza viruses (35). Foster (14) showed that proflavine concentrations which do not inhibit bacterial growth, inhibit completely the multiplication of T_4 and T_6 viruses. The concentration of inhibitor required is inversely related to the length of the latent period. Of importance is the finding that when introduced during the latent period proflavine effectively inhibits viral multiplication. Inhibition of T_2 and T_4 is obtained when the drug is added 12 to 15 minutes after infection, a period about equal to one-half of the latent period. When proflavine is added later during the period of multiplication, decreased yields of virus are obtained, the extent of inhibition is an inverse function of the time of addition of the drug. Apparently, proflavine blocks some late step in the process of multiplication but does not block earlier steps since removal of the drug during the first part of the latent period permits normal multiplication. Infected bacteria in which viral multiplication is inhibited by proflavine undergo lysis at the end of the normal latent period but do not yield any infective virus (14).

Cohen and Anderson (13) demonstrated that the multiplication of T_2 is inhibited by 5-methyl tryptophane. The inhibition is reversed by the addition of tryptophane (36). As with proflavine, complete inhibition is obtained only if the substance is introduced during the first half of the latent period. These findings raise the possibility that no infective virus is present within the cell during the first half of the period required for multiplication (14). Moreover, they suggest that multiplication is a discontinuous process during which virus particles are built up in steps and that only in the final stage are complete or mature, infective particles developed.

There are three means by which the presence of bacterial viruses can be demonstrated dependent upon their infectivity, specific antigenicity

and characteristic morphology, respectively. If multiplication occurs in steps, then antigens characteristic of the virus might be present before infective particles are evolved. There is no evidence available on this point with bacterial viruses. However, recent studies by Wyckoff (37) with the electron microscope showed that during the latent period distinct particles are present in the bacterial cytoplasm. At first they are extremely small. They increase in size and number rapidly until they replace much of the cytoplasmic material, but only just before the end of the latent period do they show the sperm-like morphology which typifies the mature, infective virus. These findings support the theory of a step-wise mechanism of viral multiplication.

With influenza virus there is evidence pointing in the same direction. This agent, like a number of other animal viruses, is capable of agglutinating red blood cells and its concentration can be measured by the hemagglutination reaction *in vitro* (38). Gard and von Magnus (39), in studies on the interference phenomenon, obtained startling results which indicate that at least two varieties of viral particles are produced. One variety is incomplete or immature, capable of agglutinating red cells but non-infective and of small particle size with a sedimentation constant of 380S. The other is the classical virus, infective and capable of causing hemagglutination and of usual particle size with a sedimentation constant of 660S. Thus, it appears that influenza virus, during one stage in its multiplication, occurs in a state which is almost entirely non-infective; computations indicate that only about 0.01 per cent of the particles were actually infective (39). These latter particles, however, may be of critical importance and probably are alone capable of initiating the process which results in the development of incomplete, non-infective viral particles. In earlier work Friedewald and Pickels (40) showed that influenza virus preparations contained a component which, although devoid of infectivity, caused hemagglutination and was smaller than the complete virus.

Recently, Hoyle (41) found that antigenic components characteristic of influenza virus, but of small size, are present in infected tissue well before mature, infective viral particles appear. Henle (42) has obtained similar results suggesting that with influenza virus, as with bacterial virus, multiplication may be a step-wise process.

The completed viral particle fails to emerge until a series of stages in its synthesis has been completed.

With certain plant viruses equally unorthodox evidence is accumulating. Markham, Matthews and Smith (43) showed that crystalline preparations of turnip yellow mosaic virus contained two components which could be separated by centrifugation. One component is a nucleoprotein and infective, a classical plant virus. The other is non-infective, smaller by 50 per cent than the complete virus and devoid of nucleic acid. Both components react identically with specific anti-viral serum, have identical electrophoretic mobilities, crystallize as octahedra and are spheres of similar size. The proteins of both have the same size and shape and contain the same amino acids in similar proportions. The infective virus contains 28 per cent pentose nucleic acid, the non-infective particle, none. It appears that the presence of combined nucleic acid is essential for the multiplication of the virus. It should be emphasized that no infective virus has been shown to be free of nucleic acid (1, 25).

These observations are indicative of what may happen to viral particles during the process of intracellular multiplication. However, they do not provide information as to the indispensable role of the host cell in the process. We are still confronted by the problems: How does the virus obtain the mass and energy necessary for synthesis, how does it orient and direct cellular metabolic processes?

Cohen and Anderson (44) showed that bacteria infected with a virus stop growing but maintain a constant rate of O_2 consumption. Ultraviolet inactivated T_2 stops the multiplication of *E. coli*. Moreover, ultraviolet inactivated influenza virus inhibits the development of the chick embryo (45). Infected bacteria carry out metabolic processes which give evidence of being abnormal. The most definite abnormalities appear in the synthesis of nucleic acids. Cohen (25) found that *E. coli* infected with T_2 synthesizes desoxyribose nucleic acid exclusively, the nucleic acid which is characteristic of the virus. Protein is synthesized from the beginning of infection, DNA synthesis does not begin for 8 to 10 minutes after infection. The available evidence (Cohen 25) suggests that the synthesis of viral peptides precedes and may be essential for the synthesis of viral nucleotides. In Cohen's view (25) the "energy and substance for virus synthesis are

supplied in entirely normal fashion" by the infected cell and the virus "organizes a specific enzymatic environment for its own multiplication." Tests of the hypothesis have not yet been possible with animal or plant viruses.

Studies on the biochemical mechanism of multiplication of animal viruses are beset with serious difficulties. As yet only a very few chemical inhibitors of multiplication have been discovered. Certain complex carbohydrates, polysaccharides, inhibit the multiplication of some animal viruses. A number of polysaccharides derived from bacteria, as well as some obtained from other sources, appear to stop the multiplication of pneumonia virus of mice (PVM) (46). The capsular polysaccharides of Friedländer bacilli are most active of those tested, 20 micrograms per mouse is effective. Friedländer polysaccharides also inhibit the multiplication of mumps virus in the allantoic sac, 5 micrograms per egg is sufficient (47). Inhibition of multiplication of either PVM or mumps virus results when the carbohydrate is introduced as long as 4 days after infection.

Friedländer polysaccharides do not cause inactivation of either virus, do not combine with them and do not prevent their adsorption by susceptible cells (18, 46, 47). On the other hand, the polysaccharides are taken up by host cells and remain fixed in them for long periods (21). The extent of inhibition of multiplication is directly related, although not strictly proportional, to the quantity of polysaccharide injected. Moreover, the extent of inhibition is inversely proportional to the amount of multiplication which has occurred, or to the time which has elapsed, before polysaccharide is given. Polysaccharide does not cause any reduction in the concentration of virus present in infected tissue, but further multiplication of the virus is inhibited (46, 47).

Three lines of evidence raise the possibility that inhibition of viral multiplication by Friedländer polysaccharides results from blockade of a metabolic pathway in the host cell. 1) Inhibition of either PVM or mumps virus multiplication is obtained when polysaccharide is introduced as late as 4 days after infection is initiated. At this time the concentration of virus is so high there can be no reasonable doubt that all susceptible cells are already infected (47). This fact and the finding that inhibitory polysaccharide does not prevent adsorption of virus by susceptible cells appear to exclude the possibility that an extracellular effect is responsible for the inhibition. 2)

The multiplication of mumps virus and PVM is inhibited by Friedländer polysaccharides, whereas the multiplication of influenza and Newcastle disease viruses is not (47). Mumps virus interferes with the multiplication of PVM and, moreover, influenza and Newcastle disease viruses reciprocally interfere with each other, but neither mumps virus nor PVM prevents the multiplication of influenza viruses (29). Thus, viruses which are inhibited by a polysaccharide cause interference with each other but do not cause interference with viruses which are unaffected by the same polysaccharide. 3) Treatment of Friedländer polysaccharide with alkali results in a product which is not capable of inhibiting viral multiplication. However, such altered polysaccharide blocks the inhibitory effect of the native polysaccharide (21). The blocking action of the altered carbohydrate shows characteristics which are consistent with the idea that it acts as a competitive antagonist relative to the native polysaccharide.

It should be emphasized that only a few viruses have been employed in recent studies on the mechanism of viral multiplication and in each instance the evidence is largely indirect and far from complete. Nonetheless, there are suggestive similarities in the findings with certain bacterial, plant and animal viruses which raise the possibility that they undergo multiplication in like manner. In each instance it appears probable that the viral particle itself may be developed through steps or stages and that the complete or mature, infective particle is chemically more complex than its incomplete predecessors. Of most importance are the indications that only the complete infective particle is capable of initiating the process which results in the development of further viral particles. Speculation as to the identity of the metabolic pathways of host cells apparently required by viruses probably would be unrewarding. But it may be that one step in such a pathway is indicated by the results of studies with chemical inhibitors. As has been pointed out, certain complex carbohydrates inhibit the multiplication of some animal viruses. If these substances are indeed structural relatives, are analogues, of an intracellular substance required in viral multiplication, then it may be that a step in the metabolic pathway which is controlled by polysaccharide is essential. Such an hypothesis has merit only in that it is not contrary to the available data and may provoke further study of the problem.

THE PHYSIOLOGY OF THE INDIVIDUAL AS AN APPROACH TO A MORE QUANTITATIVE BIOLOGY OF MAN¹

ANCEL KEYS

From the Laboratory of Physiological Hygiene, University of Minnesota

MINNEAPOLIS, MINNESOTA

THE fact of individual variation is frequently taken to be merely an impediment to biological research. The customary approach is to emphasize those features that are common to all individuals and hope thereby to discern basic relations and general mechanisms. Individual variability is eliminated or minimized by taking enough individuals to get a 'good average'. With laboratory animals the numerical requirement is reduced by using inbred strains or litter mates. With man, where such expedients are almost never available, the task of sampling the whole population would be so great—and actually impossible in view of the unknown distribution of major biological characteristics—that it is really never attempted. We are confined to selected groups which may not represent any large and easily identified segment of mankind and may not even be homogeneous in those respects which are important to the problem. The most popular human guinea pigs, college students, are not necessarily very homogeneous except in regard to chronological age. In any case, the emphasis is on averages without critical definition as to source, on the one hand, and to application, on the other.

This is in sharp contrast with the practice of medicine and the general problem of evaluating individuals as in selecting airplane pilots or professors of physiology. The physician asks how his patient differs from normality, the Air Forces also ask about normality but with a different definition. And, presumably, college presidents have their own inscrutable standards.

¹This work was aided in part by a grant from the National Dairy Council, acting on behalf of the American Dairy Association, and by the Research Grants Division of the U. S. Public Health Service.

Dr. Olaf Mickelsen, now at the Division of Nutrition, U. S. Public Health Service, Washington, D. C., supervised the work on cholesterol in the year 1947-48. Miss Erma V. O. Miller, Assistant Scientist, made all of the cholesterol determinations.

It is easy enough to smile at the intuitive and empirical procedures used in medical management and in the selection of candidates for specific jobs. It is easy to be impatient with the non-discriminatory premium rates of insurance companies which presume that all 'non-diseased' persons, except for the obese, have equal disease expectations. As scientists, we should insist that there must be sound bases of a physico-chemical nature which have not been developed and utilized for such judgments. There is a very large area of human affairs in which the day-to-day operations, though concerned with human characteristics, proceed with a minimum of reference to knowledge of physiology, biochemistry, and the kindred sciences represented in the Federation. In our work there seems to have been, so far, relatively little of value for individual prediction.

This may be right and proper, perhaps these applied problems should be of no concern to us. There are three objections to this view. In the first place, if it is agreed that the physico-chemical characteristics of the individual should have predictive value, then those who are most expert at measuring and working with those characteristics should be best qualified to interpret the data. In other words, someone must be concerned with the scientific problem of the individual and in the technical area of physiology the physiologist should take the responsibility.

In the second place, consideration of the individual forces attention on the interrelations between variables, at least some of which must be hidden in the pooled data which refer to the common denominators of all dogs or all men. This means that the scrutiny of the individual should be an instructive point of departure for the study of general relations between variables in physiology and allied fields.

Finally, the experimental biologist, like the clinician, is constantly faced with the problem of deciding what is 'normal'. When does physiology end and pathology begin? But 'normal' function

may obviously be achieved by a variety of combinations of quantitatively different conditions. Moreover, values for a given characteristic which would be normal for one individual may be abnormal, that is pathological or predictive of future disorder, in another individual, depending on other characteristics and conditions. Once the problem of normality is seriously raised, logic demands successively sharpening and narrowing definitions until one comes to the individual. In essence, the problem is to place, quantitatively, the operating machinery of the individual—function and structure—in the spectrum of possibilities afforded by the species.

The simplest form in which the problem arises is in the evaluation of normality of a measurement. Having measured some characteristic of a person, the question follows: Is the person 'normal' with regard to this characteristic? To illustrate, we may consider the cholesterol in the blood, about which there is considerable interest at the moment. Basal blood samples drawn last December from two members of the laboratory staff, *Mr X* and *Dr Y*, were found to contain, respectively, 250 and 310 mg of total cholesterol per 100 cc of serum. Are these 'normal'?

Neither cursory nor exhaustive searches of the literature provide the basis for a satisfactory answer, but data recently obtained in the Laboratory of Physiological Hygiene may be analyzed for this purpose. We have values, obtained by duplicate analyses on basal blood samples, from each of 541 'normal' white men, who were leading an ordinary life in a gainful occupation not involving manual labor and who were pronounced free of detectable disease on the basis of medical examination. Their ancestral backgrounds, like that of *Mr X* and *Dr Y*, stemmed from the British Isles and Northern Europe. All measurements were made by the same methods and analysts in Minneapolis in the fall and winter months of the year. It will be observed that this material is characterized by an unusual degree of homogeneity as to source—species, sex, race, occupation, freedom from apparent disease, season, geographical location, physiological conditions and analytical method.

Surely it might be concluded that these data should provide a suitable reference standard for *Mr X* and *Dr Y*. The mean value for the 541 men is 218.7, with a standard deviation of 50.6 mg. *Mr X*'s value of 250 mg is only 62 per cent of one standard deviation above the mean and

would be expected, on the basis of normal probability, to be exceeded by about 25 per cent of the men in any normal sample like the reference group. *Dr Y*'s value of 310 mg, however, is 161 per cent of one standard deviation above the mean and a value as high as this would be expected to occur in only 5 per cent of the cases. Quantitative placement of *Mr X* and *Dr Y* has been made in good statistical terms and the first conclusion is that, with regard to blood cholesterol, *Mr X* is 'normal' and *Dr Y* has moderate hypercholesterolemia.

But, having made use of normal probabilities, it is well to check the normality of the distribution of the reference material before closing this chapter. A simple frequency-distribution plot of the data shows a reasonable form but when a true normal curve, calculated from the mean and

TABLE 1 TOTAL SERUM CHOLESTEROL, IN MG/100 ML, IN BASAL REST, IN 'NORMAL' MALES

AGE		NUMBER	CHOLESTEROL	
Mean	Range		Mean	S.D.
19	17-20	109	173.2	±30.2
22.5	21-25	92	179.5	±36.7
32	27-35	17	198.2	±25.3
43	39-44	16	222.4	±25.4
46	45-47	87	242.5	±37.5
49	48-50	98	249.1	±42.8
52.5	51-55	102	251.9	±43.0
68	63-74	20	233.9	±37.4
All ages		541	218.7	±50.6

standard deviation, is superimposed, it appears that the peak is too broad, it is 'platykurtic', and the suspicion is created that the data contained in it are not homogeneous. Obviously, the attempt should be made to segregate the 541 men into more closely defined groups.

Age was not originally considered because the literature generally disclaims a relation between age and blood cholesterol in adults (1-5). However, Brüger and Möbius (6) reported a distinct age trend. In any case, the result of segregating by age groups is given in table 1. Clearly, there is a very large effect of age. Low values in early manhood rise progressively with age, but apparently reach a plateau in the fifties, and slowly decline in the sixties. The implications are numerous and intriguing but are beside the present point which is that, for adult men, it is necessary

to specify age in considering the meaning of a particular cholesterol value

Mr X, who is 20 years old, now turns out to have a cholesterol level which is 76.8 mg above the mean of 109 men in his age group. With a standard deviation of 30.19 mg, such a value would be reached by only 0.5 per cent of the reference population and Mr X must now be labelled as definitely abnormal.

Dr Y's case is less definite, he is 50 years old and the mean value for 98 men in his age group is 249.1 mg, S.D. = 42.8. A value as high as his (310 mg) may be expected in only 7.6 per cent of normal men of his age. It is of interest to see whether a more definite result can be obtained by still closer scrutiny of his reference group.

TABLE 2 B.M.R. IN ML O₂/MIN/M² OF BODY SURFACE, AND TOTAL SERUM CHOLESTEROL, IN MG/100 ML FOR 'NORMAL' MEN 48-55 YRS OF AGE

B.M.R. CLASS	NO OF MEN	B.M.R. MEAN	CHOLESTEROL	
			Mean	S.D.
Higher (118.2-149.3 ml)	64	126.5	244.5	39.1
Medium (109.4-118.2 ml)	64	113.6	253.2	40.1
Lower (90.4-109.1 ml)	63	103.2	256.3	48.4
All (90.4-149.3 ml)	191	114.5	251.3	42.8

Since we have recorded many characteristics of these men, there is almost an embarrassment of possibilities. As a start, we may consider the basal metabolism, on the ground that blood cholesterol is often high in hypothyroidism. None of these men has myxedema but they do cover a considerable range in basal metabolism—from 90.4 to 149.3 ml of oxygen/minute/square meter of body surface in the men from 48 to 55 years of age. When the 191 men of this age, for whom full data are available, are arranged in 3 classes according to B.M.R., the result is as summarized in table 2. It is indicated that there is an inverse relation between B.M.R. and the blood cholesterol.

It would be of much interest to continue to sharpen the definition of the 'normal' standard groups, but in spite of the fair size (541) in the original total, the size of the sub-groups is getting small for the present type of analysis. For the next stage we may consider the combined medium and lower B.M.R. classes on the ground that they differ only slightly in their cholesterol averages. These 127 men have been arranged accord-

ing to relative fatness and divided into two groups with the results shown in table 3.

The criterion of fatness used was the thickness of the skin fold at a specified point on the abdomen, this choice being dictated from the results of rather extensive studies on the estimation of fatness in man. The result would be similar if only relative body weight were used, since this is closely but not perfectly correlated with the skin fold thickness. In any event, in agreement with

TABLE 3 RELATIVE FATNESS, AS ESTIMATED BY THICKNESS OF ABDOMINAL SKIN FOLD, IN MM, ('SKIN'), AND TOTAL SERUM CHOLESTEROL, FOR 'NORMAL' MEN 48-55 YRS OF AGE WHOSE B.M.R. IS BETWEEN 90.4 AND 118.2 ML O₂/M²/MIN

	NO OF MEN	SKIN MEAN	B.M.R. MEAN	CHOLESTEROL	
				Mean	S.D.
Thinner men (Skin' 9.5-24.6 mm)	64	19.2	109.0	249.8	45.7
Fatter men (Skin' 24.8-60.0 mm)	63	33.7	108.0	259.7	42.6

TABLE 4 BLOOD CHOLESTEROL AND EYE COLOR IN 127 MEN CONSIDERED IN TABLE 3 (48-55 YRS, B.M.R. MEDIUM TO MODERATELY LOW)

GROUP	N	MEAN	S.D.
Fatter men			
Brown eyes	22	265.8	±37.7
Blue eyes	41	256.4	±45.0
Thinner men			
Brown eyes	27	252.8	±31.9
Blue eyes	37	247.6	±50.4
All men with brown eyes	49	258.6	±38.5
All men with blue eyes	78	252.2	±47.0

advance suspicion, it is indicated that the fatter men tend to have the higher cholesterol values even at the same age and with substantially the same basal metabolic rates.

For a further breakdown it is at least amusing to try one more classification, using an item about which we have no preconceived notions. Eye color is known for all of these men so it may be used to classify further the same 127 men considered in the fatness breakdown summarized in table 3. The results are given in table 4.

In both fatter and thinner men of this age group

the brown-eyed men have slightly higher average cholesterol values than the blue-eyed men. Since both numbers and differences are rather small, we cannot yet conclude that there are real differences in the blood cholesterol related to eye color, but the values given in table 4 are the best estimates so far available for the particular classes of men. Such as they are, they must be used as reference standards in lieu of better ones. We may now return to the evaluation of *Dr Y* on this basis.

It so happens that *Dr Y* has a B M R of 106 cc of oxygen/square meter/minute, and an abdominal skin fold thickness of 32 mm, and his eyes are brown. His blood cholesterol value of 310 mg is only 44.2 mg above the mean for his group (first line of table 4) and that mean has a standard deviation of 37.7 mg. According to normal probability, some 12.1 per cent of men in his group may be expected to equal or surpass his blood cholesterol level and he must be judged fully 'normal' in this respect.

The foregoing is an illustration of the result of attempting to evaluate a characteristic of an individual. In the process it was necessary to give more than usual precision to the term 'normal' in the sense of 'average' and free from apparent disease. At the outset no real judgment could be made about *Mr X* and *Dr Y* because there were no real standards, much the same could be said about almost any characteristic besides blood cholesterol which might be chosen. In the first phase of the analysis, erroneous judgments were made because sources of variation in the standards were not segregated. The second, third and fourth phases of the analysis revealed a progressively changing picture. Because of exhaustion of the reference standard material, no more discrimination is possible, but it cannot be doubted that the tentative evaluation could be further improved by considering more characteristics in a larger sample. Moreover, it is conceivable that some other characteristics might be more significant and greater discrimination could have been achieved than with the characteristics tested here.

The value of refined standards such as developed here can scarcely be doubted. Equally important is the discovery of relations previously unknown or only suspected. Obviously it is now suggested that more specific research be undertaken with regard to the relations between blood cholesterol and the items considered here, namely basal metabolism, obesity and eye color. The attempt to evaluate the individual provides guidance for other research on mechanisms, though

nowhere in this analysis was there any direct consideration of those problems.

Of course, questions of mechanism were in the background when the initial question was asked as to the normality of the blood cholesterol values for *Mr X* and *Dr Y*. Currently, such a question is apt to be asked because of the belief that the level of blood cholesterol may influence or participate in the production of atherosclerosis. What *Mr X* and *Dr Y* want to know is whether their blood cholesterol indicates anything about their personal ageing processes and inclinations to earlier or later atherosclerosis. The analysis here says nothing about this but we hope that the long range program at the Laboratory of Physiological Hygiene will eventually contribute to this particular prediction problem.

Although the data are not at hand to attempt a prediction analysis regarding cholesterol and atherosclerosis, the general problem may be indicated with another example. On the International High Altitude Expedition to Chile (7) there were 9 men for whom various characteristics were recorded before they went to make a prolonged stay in the high Andes. Though all of the men were 'normal' at sea level, they showed great and consistent differences in their ability to acclimatize to altitudes above 12,000 ft (3660 meters). Were these strikingly different responses related to the differences in the recorded characteristics of the men at sea level? The analysis of this question may be summarized here because it reveals some of the essentials of the general prediction problem (8).

The differences in the individual characteristics at sea level were reliably established. At high altitude the men lived, ate and worked together, so 'external' circumstances were constant and the large differences in acclimatization must have been predetermined by inherent differences which already existed in the men at sea level. But the items we measured at sea level were not then known to be related to the factors which subsequently produced the different responses at high altitude, there were no clear clues as to which items we should measure. In the end, however, there were two sets of data, one on sea-level characteristics and one on high altitude responses, and the problem was to discover what, if any, were the relations between these.

Each item of measurement at sea level can be separately considered in the first phase of the analysis. Some of the characteristics, including vital capacity, blood pressure, muscle strength

and the Schneider cardiovascular fitness index, appeared to have little or no relation to the ability to acclimatize. But suggestive correlations were obtained with 7 of the variables as indicated in table 5. Ability to acclimatize would seem to be directly related to the alkaline reserve and to the partial pressure of carbon dioxide in the alveolar air at rest, and inversely related to age, to basal pulse rate, to body weight, to the hemoglobin concentration in the blood, and to the partial pressure of oxygen in the alveolar air.

Several of these indicated relations may be surprising but, *ex post facto*, they are physiologically reasonable. For example, it may be startling at first glance to suggest that a low hemoglobin at sea level should be predictive of high ability to acclimatize to high altitude. But the person who normally maintains a high hemoglobin concentra-

TABLE 5 CORRELATIONS BETWEEN OBSERVED ABILITY TO ACCLIMATIZE AT HIGH ALTITUDE AND VARIOUS CHARACTERISTICS RECORDED AT SEA LEVEL BEFORE GOING TO HIGH ALTITUDE. DATA FROM KEYS ET AL (8)

SEA LEVEL CHARACTERISTIC	CORREL COEFF
Basal pulse rate	-0.61 ±0.13
Alveolar pO ₂	-0.59 ±0.14
Alveolar pCO ₂	+0.63 ±0.13
Arterial blood alkaline reserve	+0.60 ±0.14
Blood oxygen capacity	-0.59 ±0.15
Age	-0.53 ±0.18
Body weight	-0.42 ±0.18

tion to meet the sea-level condition of oxygen supply can be considered to have a reduced margin to meet the more difficult situation at high altitude. Similarly, the person who habitually gets along at sea level at a ventilation level which amounts to relative 'underbreathing', may be considered to have a more efficient, or at least more economical, respiratory characteristic. This man will, of course, tend to have, at sea level, a low alveolar pO₂ and a high pCO₂.

In any case, these correlations indicate that each of these 7 variables has some predictive value for ability to acclimatize. We may inquire as to whether they may be combined so as to provide a more perfect index or measure of the factors which determine the ability to acclimatize. This would seem likely since at least some of the measured variables are not strongly intercorrelated. Four of the characteristics which have the great-

est independence may be combined in a least-squares solution for the prediction of acclimatization. The result is

$\text{Acclim} = K + 8.89 \text{ Alk Res} - 2.15 \text{ pO}_2 - 1.82 \text{ age} - 1.63 \text{ weight}$ (9). The acclimatization ability predicted from this equation is compared, in table 6, with that actually observed. The agreement is good and is statistically significant with the 9 men on whom it was tested.

It could be suggested that, since there were 7 sea-level characteristics which seemed to be related to later acclimatization, a better prediction equation could be evolved by combining all of them in a similar least-squares solution. This may be done, of course, and the final result of computation is given in table 6 (7 factors). But though the 'fit' is slightly better, the computational proce-

dures are more laborious and the statistical significance is actually lessened because of the larger number of coefficients (9).

There would seem to be several values in this analysis: 1) unsuspected relations between variables were revealed, 2) suggestions were made as to critical items for study in regard to the mechanism of acclimatization, 3) it was shown that some variables may be profitably combined though otherwise we should not think of them as being associated, 4) a prediction formula was obtained for trial with other groups. It is reasonable to believe that a like outcome would emerge from a similar systematic attack on other problems of prediction besides the high altitude example cited here.

The two examples used in this discussion, deal-

ing with blood cholesterol and with acclimatization to high altitude, were chosen in part because in both cases there was a minimum of guidance available from considerations of cause and effect and qualitative biological theory. The deliberate choice was made of questions for which frontal attack on the actual questions asked could be attempted, at the present stage of knowledge, only by methods which are largely empirical in a biological sense. Unfortunately, it seems that the development of a true quantitative biology is still so rudimentary that the majority of questions pertaining to the physiology of the individual must be attacked with a similar emphasis on empirical methods, normal cholesterol standards and high altitude acclimatizations are by no means exceptional in this regard. This is not to decry in the least the virtue of a more theoretical approach. Given enough knowledge of theory and quantitative information on the mechanisms, both of the problems discussed here could probably be more easily and surely solved. The point is that such knowledge is now lacking and, as a matter of fact, a good deal of empirical gathering of data, plus rigorous analysis, is necessary to create the wanted body of knowledge.

It should be observed that even when a relation has been mathematically established between two variables, or between a present characteristic and a future development, this does not necessarily mean there is any direct cause and effect relationship. While this is a serious limitation, the fact of some kind of a relationship offers both a challenge and a clue to further study. Moreover, the habit of reasoning solely in terms of likely mechanisms is also objectionable unless supported by direct quantitative evidence. A simple example may be taken from the cholesterol data discussed here.

Lately, the suggestion has been made repeatedly that the development of atherosclerosis may be reduced or delayed by a reduction in the dietary intake of cholesterol on the ground that with a smaller intake there would be less cholesterol in the blood available for deposition in the arteries (10). A good many middle-aged people are being advised by their physicians to avoid eggs, butter, milk and fat meats on this account. Now it so happens that we have data on the habitual cholesterol intake of 312 of the men whose blood cholesterol levels have been examined. These men have been grouped according to their habitual cholesterol intakes and the groupings have been separated according to age.

The results are summarized in table 7. Neither in the younger (18-25 years) nor older (45-55 years) men is there any relation between blood cholesterol and the habitual intake of cholesterol, in spite of the fact that the differences in the latter are large.

The purpose of this discussion has not been to present data or even theories, but only to call attention to a point of view and an area of problems. It should be particularly observed in connection with the cholesterol data used to illustrate the argument that it is not, for the present, important whether the relations observed in the men studied at Minneapolis will apply precisely to other groups of apparently similar men. Using the Minneapolis data as a reference—and we must use these, at least temporarily, in default of

TABLE 7 BLOOD SERUM TOTAL CHOLESTEROL, IN MG/100 ML, AND HABITUAL DIETARY INTAKE OF CHOLESTEROL, IN GM/WK, IN NORMAL MEN 18-25 ('YOUNGER') AND 45-55 ('OLDER')

any other—the best judgment of normality about *Dr Y* is made from the mean value, and standard deviation, for brown-eyed fat men, aged 45-55, who have medium to low rates of basal metabolism. We have not here asked any questions about the statistical significance of the apparent differences between the various groups segregated according to B M R, fatness, age and eye color. These questions are currently being examined, with a larger body of data, at the Laboratory of Physiological Hygiene.

The exploration of the frontiers of useful knowledge in the biological sciences increasingly demands a more quantitative approach which is apparent when specific questions are asked about individuals. Whenever individuals are concerned, it is necessary to consider their variation. When ever individual variation is examined it is clear

that there are such important interrelations between characteristics that the classical approach of isolating variables into single pairs (dependent and independent) must be used with care. The assumption of homogeneity is too readily made and the custom of dealing only with averages delays the recognition of the total truth.

The goal of all natural science is accurate, quantitative prediction. In the area of human health and disease, this begins with the problem of normality and normal standards. With the extension to development with time, these become more than devices for present classification of individuals and populations, they become the essential apparatus for prediction. But, because of the interdependence of most biological characteristics, simultaneous multi-variable analysis is required. This imposes the burdens of more rigorous selection and characterization of the

particular animals and men studied and the use of larger numbers and more complicated mathematical analysis. With all this, the need for true cause-and-effect understanding is not lessened. Pure empiricism has its limitations, no matter how systematic it may be.

We all realize that the development of the biological sciences is still in an early phase and a true quantitative science of biology remains for the future. I have tried to indicate that work on problems of individual physiology must be an essential part of the coming age of quantitative biology. One may approach these problems from the basis of questions about normality or about the prediction of future characteristics, the logical result is substantially the same. Finally, it may be agreed that the fact of individual variability represents far more than a technical obstacle to research, it offers a difficult but intriguing field for research in its own right.

SOME COMMENTARIES ON ELECTRON MICROSCOPY AS APPLIED IN BIOLOGY

FRANCIS O SCHMITT

From the Biology Department, Massachusetts Institute of Technology

CAMBRIDGE, MASSACHUSETTS

IT is now some fifteen years since biological objects were first observed in the electron microscope. In this brief period, during which electron microscopes were made available commercially and a number of important preparative techniques were developed, it has become clear that electron microscopy is destined to play an important role in future biological and medical research. It is the purpose of this paper to discuss some of the technical procedures upon which these advances depend and to mention briefly a few of the contributions which electron microscopy has already made in the biological field. Finally, since this symposium concerns problems of experimental pathology, a few observations will be made concerning the application of electron microscopy in pathology.

RESOLVING POWER AND RESOLUTION

The resolving power of a particular electron microscope is determined by its construction and proper operation. The degree to which this inherent resolving power can be realized in the examination of a particular preparation depends importantly upon the nature of the material in the preparation. For example, if an electron microscope has a limiting resolving power of 25 Å, resolution of this order may be realized if the particles to be examined are of high electron density (e.g., colloidal gold). However, if the same instrument is used in the examination of relatively large protein fibers the resolution obtainable may not exceed 100–200 Å. In this case the large size of the particles and the low electron density of their constituent atoms may make it possible to realize but a fraction of the resolving power of the instrument. If the resolution (distance between centers of the closest particles which can be clearly distinguished as separate) is correctly determined the danger of drawing unwarranted conclusions as to the significance of images seen in electron micrographs will be reduced. There has been some tendency among biologists to infer

resolutions considerably greater than the micrographs justify. Indeed, one of the problems of the biologist is to prepare his specimens so as to obtain the maximum possible resolution of the objects of special interest in the specimen.

Some Technical Developments

The procedures of particular interest to the biologist are those which permit him a) to obtain the constituent of interest in a form which is most amenable to electron microscopic examination and b) to obtain information about thickness and detailed structure of the constituent. Some of the more useful of these may now be discussed.

Thin sectioning. Early attempts (1–3) to obtain sections of cells and tissues sufficiently thin for useful examination with the electron microscope (0.05–0.1 μ) were cumbersome and yielded but a small fraction of suitable sections. The development of high-speed sectioning (4–6) aroused considerable interest among biologists. A number of papers have been published showing electron micrographs of normal and pathological tissues sectioned by this method. However, the results left much to be desired, either because of relatively low resolution or because of poor preservation of the tissue structure.

The theoretical basis for the necessity of high velocity impact of the knife on the specimen has never been convincingly developed. Indeed, it has recently been shown by Pease and Baker (7) that quite satisfactory thin sections may be obtained with the conventional rotary microtome which has been fitted with a simple device to permit very small cutting increments. These authors have obtained electron micrographs of liver cells, muscle and other tissue which are of a quality at least as high as those obtained with the high-speed microtome though in few instances outstandingly superior to those obtained with the light microscope.

As in conventional cytology, the success of thin sectioning in the electron microscopic examination of tissue structure depends very largely

upon the preliminary fixation and embedding. Conventional methods are not suitable and much development will be required since the criteria of success are different than in the case of light microscopy. Doubtless special methods will have to be developed for each type of material. The mere fact that sections may be obtained which are sufficiently thin to be penetrated by the electron beam does not necessarily mean that the electron micrograph obtained will reveal considerably more information at a magnification of 10,000 than was revealed by conventional cytological methods at a magnification of 1,000. This is partly due to the fact that the process of fixation may precipitate materials upon the structures to be examined in a manner such as to prevent resolution of the details of structure within the object.

Thus the problems of fixation may plague the new generation of morphologists who use the electron microscope even more than it did their predecessors who used the light microscope. However, it is to be hoped that the mechanisms of fixation itself may now be amenable to a much more penetrating analysis since the electron microscope is capable of reaching down to the molecular level in visualizing the alterations which proteins and other organic substances undergo when treated with fixatives. At this level the study of fixation is the study of the composition and structure of the protein molecules themselves, a goal worthy of intensive effort.

Fragmentation methods. It was more or less generally assumed that significant advances in the electron microscopy of tissues could be made only by the development of thin sectioning techniques. However, it has already been demonstrated that the use of appropriate fragmentation techniques may yield highly significant results.

In the case of striated muscle it was demonstrated that from formalin fixed tissue fragmented with a blender, or with sonic oscillations, bits of myofibrils could be prepared which are susceptible of very profitable examination with the electron microscope (8). In such preparations it was possible to resolve the individual actomyosin filaments and to demonstrate that they course in parallel bundles through both the anisotropic (A) and isotropic (I) bands. This disproved the concept that the relative isotropy of the I bands is due to disorientation of the filaments in these regions. It was also shown that, in contraction, the filaments thicken and shorten but are not

thrown into coils or folds, hence the contractile elements are considerably thinner than the actomyosin filaments (ca 150 Å). There is also evidence for the existence of a periodic variation of density, thickness, or both, of the filaments in the axial direction. The period is of the order of 400 Å, which agrees with that obtained by x-ray diffraction studies of muscle (9) and of actin (10, 11). The manner in which this period varies with contraction or tension production has not yet been established with clarity, it is possible that further study of this aspect may throw important light on the contractile mechanism.

Another example of the use of fragmentation methods is provided by recent studies of the nerve axon (12). Frozen sections of formalin fixed nerves were fragmented with sonic oscillations. Fibrous structures were observed in the supernate. The fibrils characteristically have dark edges which suggested the term 'neurotubule'. After staining with phosphotungstic acid or after shadowing with chromium the fibrils manifest an axial periodicity in the form of cross-bands. The period averages about 650 Å, which is identical with that of collagen fibrils. This poses a difficult problem. Peripheral nerve fibers are invested with collagen fibers and, since the specimens are prepared by fragmentation of whole nerve it was necessary to demonstrate that the fibrils actually occur in the axon and are not merely extra-axonic collagen fibers which have acquired dark edges by the method of preparation, perhaps by adsorption of dispersed myelin material. The view that the fibrils are axonic in origin was supported by the fact that they were observed in fragmented axons isolated from the giant fibers of the squid and by the fact that after nerve degeneration the fibrils could no longer be observed (13).

This example illustrates the difficulty of localizing structures obtained after fragmentation of whole tissues. The difficulty happens to be particularly emphasized in the case of nerve because of the close similarity of the presumably intracellular structures with those of the extracellular collagen fibrils. The sampling difficulty is very prominent in this problem.

Tissue cultures. Another method of observing intracellular structures without the use of sectioning is that of tissue cultures. The cells are grown in a thin film so that they tend to flatten out and remain quite thin. When the culture has reached the desired stage the cells are fixed and transferred to metal grids for observation in the electron microscope. Various types of struc-

tures have been observed, including the limiting cell membrane, mitochondria, particulates of different kinds and, in certain malignant cells, dense particles which may be viruses (14-16) Fixation is also critical in such work not only as to the kind of fixative but also the duration of fixation, the structure may be strikingly different after 15 minutes' fixation in osmic acid from that after fixation for 45 minutes

With the current development of tissue culture techniques, particularly with respect to synthetic media, it is probable that the number of cell types and problems which may be studied by this method with the electron microscope will be greatly increased

Staining One of the most useful techniques employed by the histologist is that of elective staining by means of which he is able not only to achieve heightened contrast between tissue constituents but also to obtain information about the chemical nature and electric charge of the structures which combine with the stain

Stains are also valuable in electron microscopy However, in this case the heightened contrast depends on the electron density of the stains rather than their color, they are essentially 'electron stains' They are useful to the extent that they can attach molecules containing atoms of large weight to specific tissue constituents or to localized regions in these constituents Biological materials are composed predominantly of atoms of low weight Therefore some stains customarily used in histology may be useful as electron stains because of the presence of a few atoms of higher weight These stains have not yet been extensively explored Rather, emphasis has been placed on substances which contain atoms of great weight (17) Particularly useful are the coordination compounds of the heteropolyacids Osmic acid, which was early used in electron microscopy, is also an effective stain Phosphotungstic acid (PTA) has been extensively used in this laboratory though phosphomolybdic and uranyl phosphotungstic acids are also effective

Electron stains have been used very successfully in bringing out the fine structure of fibrous proteins Particularly striking is the case of the fibrils of the adductor muscles of molluscs Unstained fibrils show usually only an irregular, mottled appearance After staining with PTA, a periodic cross-banding, with spots occurring in a regular array along the bands, was observed (18) This structure agrees remarkably closely with

that deduced from small-angle x-ray studies (19) Detailed intraperiod banded structure was also observed in collagen fibrils after staining with PTA

Electron stains may function both in a specific and a non-specific manner Thus PTA may combine with specific basic groups in proteins depending on pH, concentration and so on To what extent such specific affinities may reveal the location of particular chemical groups in the structure stained remains to be seen As usually used, electron stains probably act in a relatively non-specific manner, essentially revealing local differences of thickness Detailed intraperiod structure with six or more bands can be observed in collagen fibrils stained with PTA (20-22) However, under favorable conditions, similar structure though with low contrast, can be seen in unstained fibrils From metal-shadowed specimens it was concluded that the bands which stain with PTA are regions of relative thickness It is possible therefore that the heightened contrast obtained with PTA is due in part at least to a non-specific volume effect

It seems quite possible that certain of the cytochemical procedures developed for the localization of specific chemical groupings, enzymes and so on, may be applicable in modified form in electron microscopy The writer has been investigating this possibility in the case of the acid phosphatase reaction which involves the formation of an insoluble lead salt about the structure containing the enzyme In this case the heavy metal would constitute an electron stain for this specific enzyme Success in such investigations will probably depend on the degree to which the reaction can be made truly specific

Heavy metal shadowing This technique, developed by Williams and Wyckoff (23, 24), has proven enormously valuable in biological as well as in most other types of electron microscopy When properly applied, shadowing reveals extremely small details of structure Indeed, already in the early days of its application in the study of viruses, thin protein filaments and even globular protein molecules themselves, the inherent structure of the film on which the specimen is deposited became a limiting factor The search for a film which is essentially structureless to within the resolving power of the electron microscope is still in progress In the meantime, film difficulties may be partially avoided by depositing the material in sufficient thickness to cover the

film completely and observing the discontinuities on the surface of the material. Precaution must be taken to avoid aggregation of the metal atoms by the action of the electron beam during examination in the electron microscope. Thus gold has a strong tendency to aggregation and this has given rise to erroneous conclusions in some instances where this metal was employed. Such difficulties are minimized by the use of metals like chromium, platinum and uranium.

Replicas Plastic replicas were originally developed for the study of the surface structure of metals and other opaque objects. Excellent electron micrographs have been obtained of the structure of tooth and bone (25-27). With the early successes with replicas it was hoped that the method might be applied to sections of tissues. However, thus far little has been accomplished in this direction, the chief difficulty is in successfully removing the plastic film from the tissue.

In its application to the study of the finest details of structure the replica technique suffers somewhat because of the finite size of the plastic particles and because of alterations which occur either to the specimen or to the replica at one or another of the steps in the procedure. Resolutions greater than 50-100 Å are seldom achieved. By shadowing the replica film very slight differences in elevation are brought out.

While it is impossible to observe biological structures in their normal aqueous environment in the electron microscope, it is possible to obtain replicas of moist material and in this way to get some information of the surface structure. This has been done in the case of bacteria in their culture medium (28-30) and also with collagen fibrils (31). Replicas of dried collagen fibrils show the characteristic periodic surface elevations corresponding to the cross-bands. Replicas of slightly moist fibrils show a smooth contour. This is consistent with the x-ray diffraction results (32) which indicate that, unlike dry collagen, the moist collagen fibril is essentially a smooth cylinder, loss of water from localized regions probably gives rise to the periodic axial contour of the dried fibrils. In applying the moist replica technique it is of course important to control accurately the water content of the specimen.

The replica technique which, like that of metal shadowing, has no counterpart in standard techniques of histology, will probably prove more and more useful in biological problems as technical difficulties are overcome.

SOME CONCEPTUAL CONTRIBUTIONS

To what extent has the infant field of electron microscopy made significant contributions to our concepts of the molecular organization of cells and their constituents? It is obvious that observations of importance to the physiologist or pathologist may be made at resolutions only two or three times greater than that obtainable by the light microscope (500-1,000 Å). However, it is in the colloidal range of about 25-100 Å that the most significant advances may be expected in the next decade.

The direct visualization of animal, plant and bacterial viruses has been of great academic and practical value. Thus far relatively little progress has been made in the study of the detailed internal organization of viruses though x-ray studies (33, 34) offer some clues in the case of the plant viruses. The details of the process by which viruses undergo self-duplication have not yet been penetrated though a beginning has been made in this important problem by Wilhams and Backus (unpublished).

The investigation of chromosome structure has fared less well probably because chromosomes are difficult to prepare in a condition best adapted to electron microscope study at high resolution. Recently, from a study of thin sections of the chromosomes of *Drosophila*, Pease and Baker (35) identified certain particles with the genes. However, until more definitive reasons for this identification are adduced and higher resolution obtained, such claims must be considered with caution.

Electron microscopy has contributed substantially to our knowledge of the structure of the fibrous proteins. Since fibrous arrays play a dominant role in many vital cellular processes, the investigation of their structure, their origin in cells and tissues and their alterations in physiological processes stand high in the priority list of problems in this field.

One of the most intriguing of the properties of protein fibers is their large repeating periods which may extend to hundreds of Angstrom units both in the axial and transverse directions. X-ray and electron microscope evidence for such periods has been obtained for collagen, keratin, myosin, actin, fibrin, protozoan trichocysts and several other proteins.

These regular repeating periods serve as 'finger-prints' by which particular fibrous proteins may be identified in tissues. However, the period in

itself may suffice to characterize only the *class* of protein. To identify the particular member of the class, it may be necessary to study the detailed intraperiod structure. Thus a number of proteins, differing widely from each other in chemical composition, belong to the 'collagen class' (36). From small-angle x-ray studies (37) it has been shown that, while members of this class all have approximately the same large axial period, the intraperiod structure varies from one to the other member of the class. This discovery may prove of great interest in attempts to devise a 'molecular taxonomy,' and perhaps 'phylogeny,' of the proteins.

Aside from their identifying value the repeating patterns may be expected to reveal something about the internal organization of the fibrous proteins. Since the bands and sub-bands repeat with very great regularity, there must be an underlying regularity of molecular organization.

From present evidence it appears that collagen is composed of a parallel packing of extremely thin filaments, possibly the polypeptide chains themselves represent the unit fibrous structures. The filaments have the inherent pattern of axial periodicity, to the extent that the neighboring filaments in a fibril are in register laterally with respect to the periodic structure, the whole fibril will appear to be cross-stratified.

The keratin-myosin-fibrin class of fibrous proteins appears to have a somewhat different structure. Thus fibrous actin is made of a linear aggregation of globular actin molecules (10, 11, 38, 39). The reversible transformation from the fibrous to the globular modification is not only of great physical chemical interest in itself but may be involved in muscle contraction (40).

The structure of fibrin is of unusual interest in connection with the theory of the causes underlying the production of long repeating periods. Physical chemical measurements indicate that fibrinogen molecules have dimensions of about 35×700 Å. Yet fibrin fibrils have a very accurately repeating pattern of about 250 Å (42) and fine structure has been observed within the bands (42). In aggregating to form fibrin, how do fibrinogen molecules give rise to a repeating period bearing no obvious relation to molecular length or composition? It seems clear that such phenomena depend upon interactions of sub-molecular units. Hall (42) has suggested that such interactions must involve colloidal forces, e.g. forces exerted over considerable distances. This type of spatial adjustment of small particles so

as to produce a macro-pattern of great regularity is fundamental in the production of structure in protoplasm. Alterations in these adjustments, due to changes in chemical environment, are probably at the basis of many physiological phenomena. The underlying physical forces which determine regular inter-particle spacings, as in tactoids, have been under investigation and some clarification of the various possibilities has been achieved (43).

ELECTRON MICROSCOPY IN PATHOLOGY

The rapidity with which electron microscopy will be profitably applied in the study of the structure of abnormal tissues and of the phenomena underlying pathological alterations will of course depend upon the development of new techniques which will have to be specially devised for the purpose. However, assuming that adequate techniques were at hand, it should be stressed that before abnormalities can profitably be studied, the investigator must be thoroughly familiar with the structure of the normal tissue. Such familiarity will probably require years of work with each special tissue. Particularly vexing is the sampling problem when working at such high magnifications. Unless one is able to show that adequate sampling of the specimen has been achieved, and some rough quantitative relations established, it is difficult to demonstrate with conviction that a particular difference of structure exists between the normal and abnormal specimens. 'Normal' specimens usually show a fairly wide range of variability, depending on conditions of preparation. The extent of these variations must be at least roughly known.

Reference was made above to the fairly complex technical aspects of electron microscopy. It should not be supposed that useful application of electron microscopy to biological and medical problems can be achieved only by physicists fully conversant with electron optical theory. On the other hand it should be clear that the biologist entering the field should be prepared to spend the time required to become thoroughly familiar not only with the operation of the instrument and with the accessory techniques, but also to learn the criteria by which his results may be correctly evaluated and interpreted.

Though the difficulties to be surmounted by the biologist in applying this technique to his problems may appear to be great, the rewards that await the deeper penetration of the structural organization of protoplasm are correspond

ingly great. The expected advances will be accelerated to the extent that the lessons of the past century of histology, with its uninterpretable

artifacts, are needed and, wherever possible, the full knowledge of modern biophysics and biochemistry is brought to bear on the problems.

Symposium on Nutrition in Preventive Medicine

Chairman C. G. KING

NUTRITION AND DENTAL CARIES¹

JAMES H. SHAW

*From the Harvard School of Dental Medicine and Department of Nutrition,
Harvard School of Public Health*

BOSTON, MASSACHUSETTS

THE extensive breakdown of the teeth and their supporting structures among modern populations represents a real challenge to investigators in the broad field of public health. Some idea of the extensive destruction and loss of teeth produced by these two major causes of dental disability can be obtained from the annual cost of dental services in the United States. In 1945, approximately \$652,000,000 was spent for dental care, almost all of which was for restorative work (1), this figure actually represents 48.7 per cent of the cost for physicians' services and 13.1 per cent of the total outlay for all medical services. The Veterans Administration alone, in the last three months of 1948, spent a total of \$11,519,000 for restorative dentistry in World War II veterans (2). Since estimates have been made that the 83,000 practicing dentists in this country can care for little more than 25 per cent of the existing dental needs, the above figures represent only a part of the true picture (3, 4). Urgently as these figures indicate the need for preventive knowledge, their message seems all too weak when one is confronted in the clinic with a child in early adolescence with such rampant caries that complete extraction and full dentures are indicated.

Although technical procedures in dentistry developed through several centuries have attained a high degree of restorative perfection, not one of these gives the least promise of effecting a reduction in the incidence or rate of progress of

dental disease. Undoubtedly, the greatest hope for the prevention or retardation of either tooth decay or diseases of the supporting structures lies in the collection of fundamental knowledge about the various factors which influence the development and maintenance of the dental tissues. A wide variety of investigations need to be conducted to study the effect of various systemic conditions on 1) the differentiation, development and maturation of the teeth and their supporting structures (the gingival margin, the epithelial attachment of the gingiva to the enamel, the cementum, the periodontal membrane and the alveolar bone), 2) the metabolic processes in the mature, hard dental structures, in the supporting structures, and in the pulp and, 3) the rate of secretion, quantity and composition of saliva. A wide variety of the experimental tools and methods in the field of nutrition are readily applicable to study the relation of nutritional influences to the above dental problems. In order to evaluate the results of these investigations, full cognizance must be taken, wherever possible, not only of the length of the experiment and character of the diet during the experiment but, also of the state of development and condition of the teeth and their supporting structure, the previous history of these tissues, the ability of the experimental subject to utilize the food provided, and the hereditary constitution and the physical well-being of the control and experimental individuals, regardless of whether they are human subjects or laboratory animals.

Time does not permit an extensive historical

¹Presented in the Symposium on Nutrition and Preventive Medicine, April 1949, Detroit, Mich.

résumé of the early literature on the relation of nutrition to dental caries, but it is of interest to comment on a few of the important investigations conducted in the past with human subjects. Early research in nutrition clearly related the nutritional value of the diet consumed during the developmental period to tooth structure. These findings prompted much speculation and research on the relation of nutrition, in particular of vitamin D, both during tooth development and after their emergence into the oral cavity on the development of tooth decay in children. The experiments conducted by Mellanby in the early 30's (5) indicated that the administration of vitamin D to institutionalized preadolescent children resulted in the development of significantly lower numbers of new carious lesions than were observed in the control children. These results have since been confirmed by other investigators (6, 7). The only negative results were obtained in experiments where older children were used (6, 8, 9).

Greater reductions in the dental caries attack rate were observed by Boyd and co-workers in diabetic and in normal children fed adequate diets over long periods (10). These reductions were attributed by the investigators to the nutritional adequacy of the diet. Certain experiments pointed strongly to the maintenance of a favorable calcium and phosphorus retention (11, 12). Careful dietary counselling of outpatients has been reported by Howe, White and Elliott (13), and by Becks and Jensen (14) to give reductions in the occurrence of new lesions by a magnitude of 60 to 70 per cent. Several investigations with children have been conducted in which the results were interpreted as indicating that increases of the soluble carbohydrate content of the diet resulted in increases in the initiation and rate of development of new carious lesions in fully formed and in recently erupted teeth (15, 16). The latter investigators have felt that the reductions in dental caries experience observed by Boyd and co-workers should be attributed to the low carbohydrate content of the experimental diet and not to their nutritional adequacy. From these conflicting backgrounds arose the current controversy as to the primary cause and methods of controlling tooth decay to which there is presently no complete answer.

Much more knowledge about the effects of nutrition during tooth development and maturation upon the susceptibility to dental caries

is needed in order to explain numerous exceptions to the current hypotheses concerning the susceptibility to tooth decay. A valuable demonstration of a developmental relationship between diet and caries resistance is provided in a large volume of dental statistics which have been methodically collected in the school clinics of Europe. Sognnaes (17) has assembled and analyzed available reports on the trends in dental caries experience among European children during the past forty years. A total of 27 surveys were evaluated which included observations on three-fourths of a million children from eleven European countries, Czechoslovakia, Denmark, England, Finland, France, Germany, Holland, Norway, Scotland, Spain and Sweden. Most surveys contained data which had been collected by trained examiners at yearly intervals over a period of several years and which had been tabulated by narrow age groups for limited geographical districts. Thus, the dental caries experience of the children of a given age in any year in these communities could be compared to that of the children of the same age in any other year. These excellent aggregations of material were studied for possible effects of dietary changes which were enforced on entire populations during World Wars and in the recovery periods thereafter. Because of the long duration of some surveys, the relation of dietary changes to the susceptibility to tooth decay could be evaluated in much greater detail than would be possible in the best controlled human experiments of shorter duration. In the summary of the trends in dental caries experience recorded in these surveys, Sognnaes concluded that the teeth of European children showed a definite and relatively uniform tendency to a decreased incidence of tooth decay toward the latter part of and following both World War I and II. The reductions in tooth decay were most significant in young children and in those teeth of older children which developed and/or matured during the war years. After the initiation of wartime dietary regimens, there seemed to be several years' delay before an appreciable reduction in the susceptibility of individuals to tooth decay was observed. Following the first World War there was an even greater delay in the return to the prewar susceptibility to tooth decay. Insufficient time has elapsed since the recent war to determine how long the present low dental caries attack rate will continue.

As an illustration of the time relationship between dietary changes and susceptibility to tooth decay, the dietary and dental data collected by several groups of Norwegian investigators during World War II permits the best analysis of the difference in reduction of tooth decay noted between those teeth which developed during war years and those which had erupted before, or shortly after, the beginning of hostilities. The annual sugar consumption of Norway was listed for 1936 as 36.3 kilograms (kg) per person. In 1939 before Norway's entrance into the war, sugar was rationed in Norway to 17.9 kg per person per year. This 50 per cent reduction apparently did not significantly reduce the susceptibility of the permanent teeth of 7-year-old children to caries. Through the years 1941 to 1945, inclusive, the average consumption per year was relatively constant at about 13.5 kg, a reduction of about 60 per cent below the prewar level. In addition to the sugar, large amounts of highly refined white flour were consumed by the Norwegian peoples in the prewar period. An estimate was made that 1242 calories of the average daily caloric consumption by an adult were supplied by refined white flour, and an additional 357 calories from sugar, i.e. more than 50 per cent of the daily calories were provided by refined carbohydrates. With the beginning of the occupation, there was a complete substitution of high extraction flour for the refined white flour and, simultaneously, drastic reductions in the amount of meat, dairy products, eggs, fruits and some vegetables. The loss of calories from these sources was largely made up by cheaper vegetables, mostly kohlrabi and potatoes, wartime bread, and fish when and where available.

The dental statistics for the Norwegian survey are summarized in table 1. For the purposes of the present comparison, the best age for observations of the initiation of carious lesions in the deciduous teeth was at 2½ to 3 years of age at which time the deciduous teeth have recently erupted into the oral cavity, a similarly suitable age for observation of the caries incidence in permanent teeth was in the 7-year-old group where the only permanent teeth were ones which had recently erupted. Unfortunately, data on the incidence of caries in the deciduous teeth of the 2½- to 3-year-old group were not collected for the years 1940 to 1943, inclusive. However, by 1944 there had been a 65 per cent reduction in

the number of carious teeth and a 44 per cent reduction in the number of children with dental caries. In 1945 and 1946 there were, respectively, 80 and 88 per cent reductions in the number of carious deciduous teeth, and 66 and 80 per cent reductions in the number of children with dental caries of the deciduous teeth. A more detailed evaluation is available for the permanent teeth of the 7-year-old children (figure 1). Negligible reductions in the number of carious teeth were observed during the first 2 years of the war.

¹ From SOGNAES, R. F. *Am J Dis Child* 75:792, 1948.

² Figures for the caries are averages from the youngest age groups recorded in Norwegian surveys 18, 20, 22, 23 and 24 shown in original table 1.

³ The use of refined flour was restricted before the invasion, and limited to babies and sick people after the occupation (April 1940). The extraction of the flour was increased from 69% before the war to 85% already in 1939 and soon after 95% of the grain was utilized for flour production.

⁴ The percentage reduction of sugar is calculated from the 1936 consumption of 36.3 kg per individual per year. The severest rationing 10 kg per individual (i.e. 70% below prewar), came into effect late in 1940. From then on until 1945 Toverud (by adding periodic increases) has estimated a weekly consumption of 260 gm (i.e. 13.5 kg per year or an average of 62% reduction from the prewar level).

Then major consecutive reductions were observed in 1942, 1943, 1944 and 1945, amounting to reductions of 23, 42, 57 and 75 per cent below the 1939 figure. In other words, the reduction in carious permanent teeth in 1945 after 6 years of war was higher than in any other previous war year. No reduction in the percentage of children with dental caries of the permanent teeth was noted until 1944 and 1945 when there were

7 and 8 per cent less children with tooth decay. A comparison for deciduous teeth can be made from the Norwegian data of Toverud collected in the towns of Blaker and Fet. The reductions in dental caries in the deciduous teeth of 2-year-old, 4-year-old and 6-year-old children are tabulated for the years 1939, 1944, 1945, 1946 and 1947 in table 2. Data were not available for 1940 to 1943, inclusive. The children in these three age groups examined in 1944 had the least reduc-

ed in 1945 and 1946 had 64 per cent less carious deciduous teeth than 4-year-old children in 1939. In 1947 there was a slightly lower reduction (55%). In the 6-year-old groups of children where the deciduous teeth have been exposed to the oral cavity for 4 to 5 years, the least reduction (21%) in dental caries experience was observed in 1944. In 1945, 1946, 1947 the reduction in carious deciduous teeth had increased to 44, 47, and 56 per cent, respectively. The

FIG 1 YEAR-TO-YEAR REDUCTION of caries-susceptible teeth and carious children during the two World Wars (From SOGNAES, R. F., *Am J Dis Child* 75:792, 1948)

tions in dental caries experience even though their deciduous teeth had been exposed to the oral environment induced by wartime diets for 1, 3 and 5 years, respectively. In the 2-year-olds maximum reduction (87%) in caries-affected teeth was observed in the children examined in 1946, i.e. born in 1944 where the teeth developed in 1944 and 1945. By 1947, there was a slight increase in the dental caries attack rate. Even in 1947, the 2-year-old children had 74 per cent less carious deciduous teeth than in 1939, this despite a gradual return toward prewar diets in the two years following the cessation of hostilities. In the 4-year-old groups, the children ex-

amined in 1944 had been developed in prewar years and appeared to have profited little by wartime dietary changes. However, those teeth in 6-year-old children examined in 1947 were formed in the years 1941-42 and had profited greatly even though the last 2 years of their oral exposure had been influenced by post-war diets.

The question arises as to the adequacy of the diet of the Norwegian children throughout the war years. Relatively good data have been collected by Stoltenberg (18) who reported that the caloric requirements of the children from birth to the age of 7 years were adequately provided

From 7 to 20 years of age there was an increasing caloric deficit from an average of 370 for the youngest to 1260 in the oldest. All public school children were stated to be taller in 1943 than in 1935. Underweight children were observed in prewar years at a rate of 16 per cent of the child population, this figure had only increased to 24 per cent in 1943. Therefore, it appears unlikely that the reductions in tooth decay were due to any restriction in the caloric

² Interpretation of chart by Toverud from examinations at Blaker and Fet.

* The groups whose teeth after eruption have been exposed to an oral environment favored by the greatest wartime reduction in refined carbohydrates. Yet these are the groups which show the least reduction in caries. A "developmental" explanation is suggested in text.

consumption. In addition, Ström (19) studied the food habits of 102 families in Oslo and two smaller localities who were able to maintain a daily average of 2,847 calories (2708 to 3046) per person per day throughout 1942 to 1945, inclusive.

The marked reductions in dental caries experience among European children during the latter years of World Wars I and II cannot be explained entirely on the basis of an oral environmental effect produced by a reduction in the refined carbohydrate content. The sudden onset of restrictions in the refined carbohydrates

available for distribution and the constant amounts available for rationing in Norway throughout the years 1940 to 1944, inclusive, eliminates any argument that the reduction in dental caries incidence was gradual and prolonged because of a gradually increasing restriction in refined carbohydrates. If the oral environment, as influenced by the composition of the diet, had been the preeminently important factor in determining the dental caries experience of these children, the reduction in tooth decay should have been evident within a year or two in all children with recently erupted teeth regardless of whether the teeth were formed before, at or after the initiation of the wartime dietary regimen. In view of the long delay in the production of a reduction in dental caries experience, Sognaes (17) believed that the wartime diets appeared to have permitted the formation and maturation of teeth which were less susceptible to the development of carious lesions. Even when these teeth were exposed to the oral environment produced by post-war diets, they were highly resistant to decay. If the delay in caries reduction had only been observed in Norway in World War II, reasonable doubt might be cast upon this interpretation, since similar trends of rather uniform magnitude had been observed in ten other European countries during World War I and II, the relationship of wartime diets during tooth development to an increased resistance to dental caries appears to be well established. Despite the conclusiveness of the above relationship, there has been an almost universal tendency on the part of the European investigators who collected these dental statistics to interpret them as strong evidence of oral environmental changes without preliminary influences on the tooth structures.

There is a real need to continue to collect survey data of this type in the hope of determining how long the reduction in caries continues and whether any future change can be correlated with dietary alterations. Parallel to the collection of more human statistics, many investigations with laboratory animals are needed to evaluate the exact role of diet during tooth development. During the period from 1910 to 1945, inclusive, animal experimentation in the dental field did not keep pace with human investigation in quantity and much less in quality. The white rat was used frequently in experiments designed to test human findings with unpredictably confusing

and conflicting results. In the middle of this era, Hoppert, Webber and Canniff (20) observed that various lesions developed readily in the molar teeth of the white rat only if the experimental diet were composed largely of coarse particles. When the coarse particles were ground finely, dental caries did not develop. Thereafter investigators demonstrated that the coarse particles caused a mechanical injury to the enamel surfaces followed by tooth decay (21). When the molars of the upper jaw were extracted,

foodstuffs. Two years later, the molar teeth of cotton rats which had been maintained for periods of 10 to 14 weeks on purified rations were found to have been susceptible to the initiation and development of carious lesions (25). The composition of a typical caries-producing, purified ration is given in table 3. The incidence of tooth decay was particularly high in the third molars which were largely developed during the experimental period and which did not erupt until late in the experiment. Tests on the effect of masticating this ration made by the extraction of opposing molars indicated that there was a much less important effect of mastication upon the initiation and progress of carious lesions in this species than had been observed previously in the white rat fed the caries-producing, Hop-

FIG 2

prior to administration of the coarse particle diet, practically no lesions developed in the lower molars (22, 23). Since human caries is not believed to result from such mechanical causes, this type of regimen was untenable.

In the last seven years, satisfactorily controlled experimental circumstances have been devised for the study of tooth decay in four species of experimental animals: the Syrian hamster (*Cricetus auratus*), the cotton rat (*Sigmondon hispidus hispidus*), the common laboratory rat (*Mus norvegicus*) and the rhesus monkey (*Macaca mulatta*). In 1942, Arnold (24) observed that carious lesions developed in the molar teeth of hamsters which were fed finely ground, high carbohydrate diets composed largely of natural

pert-Webber-Canniff diet (22, 23). Further evidence that the carious lesions in cotton rat molars were not preceded by mechanical injury was obtained through the examination of ground sections of teeth and jaws after varying periods of experimental exposure. In addition, if all ingredients in the purified ration were finely powdered, the rates of initiation and development of carious lesions were not altered (26).

Examples of the need for careful control of all possible variants in caries investigations with laboratory animals are presented in tables 4 and 5. In the former, an effect of caloric restriction to produce a reduction in the initiation and development of carious lesions is recorded (27). In the latter, the results of two experiments to study if there were any effect of the type of cage and bedding upon the dental caries experience are tabulated (26). Those cotton rats housed

in screen-bottom cages had a higher dental caries attack rate than littermates maintained in cages where the sheet metal floors were covered with shavings. On the contrary, cotton rats housed in cages where the sheet metal floors were covered with paper clippings did not have any different caries experience than littermates kept in cages with screen bottoms. The

causes of the effects on dental caries experience occasioned by caloric restriction and by the type of bedding are unknown, but the effects are sufficiently great as to necessitate careful control. Sognnaes (28) has studied the caries-conducive effect of the above purified diet when fed to rodents during, as well as after, tooth development. If weanling rats, hamsters and mice born to females fed laboratory chow throughout the reproductive cycle were fed the chow diet for periods of as long as 9 months after weaning,

practically no carious lesions developed in the molar teeth. When weanling white rats and hamsters born to mothers maintained on chow throughout pregnancy and lactation were fed the purified ration for 4 to 8 months, a few carious lesions developed in their molar teeth. In contrast, when female rats and hamsters were changed from chow to the purified ration at parturition and their offspring maintained on the latter diet for 3 to 5 months after weaning, the molar teeth of the offspring developed a rather high number of carious lesions. A still higher rate of dental caries experience was observed in offspring of female rats and hamsters which had been fed the purified ration throughout pregnancy and lactation. The increases in number of molars and number of areas affected by the

carious process, and the increase in caries score which were observed for the Syrian hamster are presented in figure 3. In the mouse similar but less striking developmental effects of the purified ration during tooth development were observed. There is a very strong parallel between these studies with the rodents and the above interpretation of the trends in dental caries experience of European children. The white rat and the hamster appear to be suitable experimental animals for the evaluation of dietary influences during tooth development. One possible drawback to the use of these species is the fact that the crowns of the first and second molars are in an advanced state of development at birth and the third molars are largely formed at weaning. Thus, any

dietary effect on these stages of development has to be mediated through the maternal organism via the placenta and/or the milk. This does not seem to be a serious difficulty in view of the qualitative effect of diet during tooth development already described.

One advantage of the cotton rat in developmental studies is the early weaning age (14 days) at which time the third molar crowns are in an early stage of development. The remainder of their formation can be influenced by diets begun at weaning. Another illustration of the inadequacy of the purified diet for the development of the dental structures has been observed through this method of studying the developmental rate of the third molar in the cotton rat. Offspring maintained for 100 days after weaning on the purified diet had a retarded rate of eruption and root formation in the third molars. Among 854 cotton rats killed at this age, the upper third molars of 77 had not pierced the mucosa, an additional 81 had emerged into the oral cavity but were only partially erupted. In contrast, the upper third molars of all cotton rats maintained on natural diets until the 54th postnatal day, or longer, were fully erupted. A similar but less severe retardation in the development of the lower third molars of cotton rats fed the purified diet was observed (26).

Various studies have been made of methods for altering the initiation and rate of development of carious lesions in fully developed molar teeth of weanling cotton rats and common laboratory rats which had been bred for high caries-susceptibility. When representatives of the susceptible strains of both species were maintained for appropriate periods after weaning on the basal purified ration, a high caries attack rate was observed. If diets were fed in which the level of fat, or protein, or both were increased at the isocaloric expense of sucrose, appreciable reductions in dental caries experience were observed (26, 29). If the sole source of nutrients were mineralized whole milk, no carious lesions developed in either species of highly susceptible rodents, as much as 10 per cent of sucrose or other soluble carbohydrates by weight could be dissolved in the mineralized whole milk without any appreciable increase in the dental caries experience (26, 29). At least part of the reduced development of carious lesions observed when milk diets were fed has been shown to be due to its fluid nature (30). Thus, there are numerous dietary procedures in rodents by which develop-

ment of dental caries after tooth formation is largely completed can be influenced.

As an extension of these studies to primates, species of monkeys have been sought which were susceptible to dental caries. Although the rhesus monkey maintained on natural diets throughout life has an extremely low incidence of tooth decay, representatives of this species maintained on purified diets for long periods have been found to develop a moderate number of lesions (31). The following experiment has been conducted to determine whether certain factors which influence the development of tooth decay in rodents would have the same effect in primates. Twelve rhesus monkeys, purchased from an animal dealer after capture in their native environment, have been maintained from the time they were about 1½ years of age for an additional 3½ years on highly purified rations (32). The 6 monkeys maintained on ration I, which contains 73 per cent sucrose, have not developed any extensive degree of caries. In 2, no caries has been found by oral examination and radiographs. Four have small, slowly progressing carious lesions in the first permanent molars which were almost completely formed at the beginning of the experiment. The second permanent molars and the first and second bicuspids have been formed to a large degree while the monkeys were maintained on the purified ration and have recently erupted. Insufficient time has elapsed since their eruption to permit development of detectable carious lesions. The 3 monkeys maintained on ration II, in which all sucrose has been replaced by fine dextrin, have only developed a few minute lesions. One is caries-free, and 2 have slowly progressing lesions in the first permanent molars. The three monkeys maintained on ration III, in which one-half of the sucrose has been replaced isocalorically by lard, have as yet developed no carious lesions.

In contrast to the above monkeys, 4 rhesus monkeys were transferred to purified ration IV containing 64 per cent sucrose at a much younger age and have in a much shorter period developed definite carious lesions even in the generally less susceptible deciduous dentition. Two were born in captivity in the colony of the Obstetrics Department of the Yale Medical School. Both developed definite carious lesions in the deciduous teeth within a few months after the purified ration was first fed. The other two, one male and one female, while born in the wild were transferred to the purified ration at the time of weaning. In

both cases, the second deciduous molars have definite carious lesions after a year's maintenance on the purified ration, during which time their weight has doubled

The demonstration of the above contrast seems to merit considerable further investigation. The fully formed teeth of the older monkeys, reared in the wild, appear to have a great caries-resistance, which even the high sucrose ration with the demonstrated ability to produce a high dental caries attack rate in caries-susceptible rodents, has been unable to fully overcome in 3½ years. True, even the older monkeys maintained on this ration exhibited more tooth decay than comparable monkeys maintained on natural diets. However, none of the older monkeys attained the degree of caries observed in the 4 younger monkeys which were transferred to the purified ration regimen at an earlier period of development.

In summary, there appears to be little question about the importance of nutrition during tooth development and maturation in determining the susceptibility to dental caries. At the present stage of the investigations, there is insufficient data to justify speculation as to the identity of the active factor, or factors, which mediate this effect or the mechanism of operation. In most future studies, it will be necessary to define the stage of development of the teeth under investigation and wherever possible, the dietary circumstances which preceded the experimental period. Both human surveys and animal experimentation justify the conclusions: 1) teeth can be developed by proper nutritional regimentation which are highly resistant to tooth decay under extreme caries-producing circumstances, and 2) teeth which are highly caries-susceptible at the time of emergence into the oral cavity can be protected from the carious process to some degree by dietary methods. It is scarcely necessary to emphasize that our present knowledge in this subject can be considered as little more than a fundamental introduction into a complex and controversial problem. The prevalence of dental caries and its sequelae, inflammation of the pulp, cysts, abscesses and further focal and systemic infections indicate the necessity for extensive exploration of the relationship of nutrition during dental development, maturation and maintenance.

The author expresses his appreciation for the contributions of his colleague, Dr Reidar F

Sognaes, to the investigations described above and to the preparation of this review. We are indebted to the John and Mary R. Markle Foundation, the Nutrition Foundation, Inc., the Sugar Research Foundation, Inc., and the United States Public Health Service for financial support of various projects.

AMINO ACID REQUIREMENTS OF MAN¹

WILLIAM C ROSE

*From the Division of Biochemistry, Noyes Laboratory of Chemistry,
University of Illinois*

URBANA, ILLINOIS

THE isolation and identification of threonine (1, 2) rendered it feasible, for the first time, to support growth upon diets carrying appropriate mixtures of highly purified amino acids in place of proteins. By the successive removal from such diets of single amino acids, the nutritive role of each was established (3). The results demonstrated that, for the growing rat, ten amino acids are essential dietary components. These are valine, leucine, isoleucine, threonine, methionine, phenylalanine, tryptophan, lysine, histidine, and arginine. The exclusion from the food of any one of these, other than arginine, leads to a profound nutritive failure, loss in weight, diminished appetite, and eventual death. In contrast to these spectacular effects, arginine deprivation merely decreases the rate of gain (4). This is accounted for by the fact that arginine can be synthesized by the rat (5), but not at a rate which keeps pace with the needs of the organism for maximum growth. This behavior distinguishes arginine from the amino acids of the non-essential group. The latter apparently can be manufactured in sufficient amounts to meet fully the requirements of the animal.

The above experiments provide much information concerning the types of synthetic reactions which the animal organism can and cannot accomplish. However, the ultimate objective throughout our investigations has been the establishment of the amino acid requirements of man. It was anticipated that time and expense might be saved by first conducting the animal tests, and then applying the results thus obtained to the more difficult and costly studies upon human subjects. Subsequent events have fully justified this supposition.

Investigations in the human species were first undertaken in this laboratory during the autumn

of 1942, and since then have been in progress continually. Publication of the detailed findings has been postponed deliberately in order to permit the accumulation of a large number of data upon a comparatively large number of individuals. It was hoped thereby to diminish the probability of errors in interpretation. The results now appear to be sufficiently numerous and definite to warrant positive conclusions.

Healthy male graduate students have served as the experimental subjects. In formulating the diets, only those articles of food were selected which are virtually devoid of nitrogen of an unknown nature. These consisted of corn starch, sucrose, butterfat (which had been melted and centrifugated to remove particles of protein), corn oil, inorganic salts, and vitamins. The starch, corn oil, inorganic salts, and parts of the sugar and butterfat were mixed with water and baked into wafers. The remaining portions of butter and sugar were consumed separately, the former as a spread for the wafers, and the latter as a flavoring agent for the amino acids. The vitamins were supplied in the form of daily doses of cod liver oil, thiamine hydrochloride, riboflavin, pyridoxine hydrochloride, nicotinamide, ascorbic acid, calcium *D*-pantothenate, α -tocopherol, 2-methyl-1,4-naphthoquinone, and a concentrate of liver (6) equivalent to 5 gm of Wilson's 'liver powder 1:20'. The amino acid mixtures furnished 6.7 to 10 gm of nitrogen daily, and were taken in solution flavored to taste with filtered lemon juice and sugar. From such a diet, the daily intake of nitrogen of an unknown nature amounts to 0.30 to 0.35 gm.

The results of the *qualitative* tests have already been summarized elsewhere (7), and need not be repeated here. The details of the procedures and findings will be published at a later date. In the meantime, it is sufficient to present the final classification of the amino acids. This is shown in table 1.

As will be observed, the amino acids which are required by adult man for the maintenance of

¹The investigation herein described was made possible by liberal grants from the Nutrition Foundation, Inc., and the Graduate College Research Fund of the University of Illinois.

nitrogen equilibrium are identical with those previously found necessary for the maximum growth of the rat, except in the case of histidine and arginine. The findings with respect to arginine are not surprising inasmuch as the adult rat (8) and the adult dog (9) have been shown to be capable of manufacturing this amino acid at rates commensurate with its use for maintenance. On the other hand, the observation regarding histidine was quite unexpected. This amino acid is required by all higher animals thus far tested. Despite this fact, its exclusion from the diets of the human subjects induced no change whatsoever in the state of the nitrogen balance. At first, the results were viewed with skepticism. It was suspected that histidine had found its way into the food despite the intensive purification

TABLE 1 CLASSIFICATION OF AMINO ACIDS WITH RESPECT TO THEIR ROLE IN MAINTENANCE OF NITROGEN EQUILIBRIUM IN NORMAL ADULT MAN

ESSENTIAL	NON ESSENTIAL
Valine	Glycine
Leucine	Alanine
Isoleucine	Serine
Threonine	Cystine
Methionine	Tyrosine

Tryptophan	Proline
	Hydroxyproline
	Histidine
	Arginine
	Citrulline

of the amino acids. Careful tests excluded this explanation. Furthermore, repetition of the feeding trials with other subjects led to identical conclusions. To date, 42 individuals have been kept in nitrogen balance upon diets which were devoid of this amino acid. Evidently, histidine, like arginine, is not an essential dietary component for the maintenance of nitrogen equilibrium in human adults. Whether the growing child, like the growing animal, requires histidine, arginine, or both of these amino acids, must await the results of further investigations. Moreover, one cannot yet exclude the possibility that certain amino acids which are not necessary for nitrogen equilibrium in normal subjects under ordinary circumstances may become indispensable during disease, or for special body functions such as detoxication, reproduction, or lactation.

Having established *qualitatively* the amino acid requirements of normal man, *quantitative* studies were next undertaken. The objective in the latter was to discover the minimum intake of each of the 8 essentials which is capable of permitting nitrogen balance when the diet furnished sufficient quantities of the other 7, and an adequate supply of nitrogen for the synthesis of the non-essentials. In the following pages attention is directed particularly to this aspect of the problem.

Before proceeding further, the reader should be appraised of certain limitations inherent in nitrogen balance studies, particularly when applied to the establishment of minimum requirements. The first of these is associated with the daily fluctuations in nitrogen output encountered in investigations of this sort. Regardless of how accurately one may control the nitrogen intake, and how diligently he may prescribe the routine physical activities of the subjects, moderate day to day variations in the excretion of nitrogen are observed almost invariably. This fact is not limited to experiments involving amino acids. It is equally true of subjects upon protein diets. Perhaps the explanation is to be found in slight alterations in the daily rate of metabolism or of excretion, or possibly in the degree of muscular tonus. In any event, the factors responsible appear to be beyond the present range of experimental control. Certainly, the fluctuations to which we refer are not to be accounted for by errors in the collection of the excreta. In order to minimize alterations in nitrogen loss via the perspiration, all of our tests were terminated before the onset of hot weather.

These variations due to unknown factors are of little consequence when one is making a qualitative experiment. The effects exerted by the exclusion of an essential amino acid from the food are so profound that they are unmistakable. However, after a moderate change in the intake of an indispensable dietary component, the alteration in the nitrogen balance is usually correspondingly small. Therefore, in all of our quantitative experiments the policy has been adopted of inducing a distinctly negative balance at some stage of the test, and then raising the intake of the amino acid under investigation until a consistently positive balance, as measured by the average for a period of several days, was attained. In this fashion, daily fluctuations are leveled, and the results are exceedingly clear-cut. In most

instances, no attempt has been made to establish the minimum level more accurately than within 0.1 gm. of the L amino acid

Another observation which has proved to be somewhat disconcerting is the difference in the minimum amount of an amino acid which is required by different individuals under comparable experimental conditions. Originally, we had hoped that two quantitative experiments with each amino acid would suffice to establish the minimum requirements of man. This assumption was soon found to be incorrect. With certain amino acids, the results are quite consistent from one subject to another. With other amino acids, the quantities found necessary vary as much as 100 per cent in different individuals. Moreover, no correlation appears to exist between the requirement on the one hand and the body weight, body surface, or creatinine output on the other. Whether such data indicate that certain essential amino acids can be synthesized in part, but with varying success by different subjects, or whether they merely reflect the extent to which alimentary microorganisms participate in the syntheses, cannot be stated at the present time. Experiments in rats appear to demonstrate that alimentary microorganisms play a much less dominant role in the formation of amino acids than they do in the synthesis of vitamins (10). Regardless of the explanation, the variations in individual requirements serve to demonstrate the tentative nature of the quantitative findings. This fact has always been emphasized when reference has been made by us to any part of these studies. Furthermore, when several subjects show different requirements for a given amino acid, the highest level must be taken as the minimum. Any 'recommended intakes' must make further allowances for the possibility that certain individuals may need still larger quantities than the subjects thus far tested. This aspect of the problem will be considered below.

Perhaps the most disturbing, and certainly the most surprising, feature of experiments involving the use of diets containing mixtures of amino acids relates to the caloric requirements of the subjects. It has been our experience that with such diets the caloric intakes must be increased above the expected levels in order to maintain nitrogen balance. This is true even when the amino acids furnish 7 or more grams of nitrogen daily. We had assumed that intakes of 40 calories per kilo of body weight per day would be

sufficient. This, however, proved not to be the case. It seemed necessary, therefore, to compare the caloric needs of individuals, under otherwise identical conditions, when they were ingesting diets containing respectively casein, hydrolyzed casein, and mixtures of pure amino acids as sources of nitrogen. One of 3 such experiments is summarized in table 2.

Throughout the test the daily nitrogen intake was kept within a range of 10.03 and 10.08 gm., and the ratio of calories from carbohydrates to calories from fats was maintained at 2.6. The diets were similar in composition to those employed throughout the quantitative investigations. The acid-hydrolyzed casein was supplemented with L-tryptophan. The mixture of 9 amino acids was composed of the 8 essentials with sufficient added glycine and urea² to raise the

TABLE 2 CALORIC REQUIREMENTS ON DIETS CONTAINING PROTEINS OR AMINO ACIDS

Period averages Subject W A S, 71.7 kilos

SOURCE OF DIETARY N	DURATION OF PERIOD	DAILY INTAKE OF CALORIES	AVERAGE DAILY N BALANCE
	days	per k b w	gm
Whole casein	6	45	+0.48
	7	35	+0.14
Acid-hydrolyzed casein	8	35	-0.29
	6	45	+0.50
9 Amino acids	5	45	+0.33
	6	35	-0.91
20 Amino acids	6	35	-0.93
Whole casein	5	35	+0.46
Enzymatically hydrolyzed casein	6	35	-0.09

nitrogen content to the desired level. Hence, the only variables were the sources of nitrogen and the fuel value of the rations.

The subject came into positive balance promptly upon the casein diet when the latter furnished 45 calories per kilo of body weight per day, and continued in positive balance during the 7 days in which the fuel value of the food was reduced to 35 calories per kilo of body weight.

²As pointed out later in this paper, extensive investigations in this laboratory have shown that glycine and urea can serve, in the growing rat, as sources of nitrogen for the synthesis of the non essential amino acids. This is true even to a greater extent of ammonium citrate.

However, when the whole casein was replaced by acid-hydrolyzed casein supplemented with L-tryptophan, negative balance ensued until the caloric intake was raised to the higher level. Like results were observed with the mixtures of pure amino acids. With the 35 calorie intake, neither the mixture of 9 amino acids (the 8 essentials plus glycine and urea) nor the mixture of all known protein components including citrulline (but without urea) was capable of inducing nitrogen equilibrium. Furthermore, no difference could be detected in the nutritive quality of the two mixtures for maintenance purposes. Several months later, the same subject was used in a comparison of whole casein and enzymatically hydrolyzed casein, as recorded in the last two lines of table 2. As will be observed, he was brought into strong positive balance upon the casein diet with a fuel intake of 35 calories per kilo of body weight. Replacement of the whole casein by the enzymatically hydrolyzed product led to a slight negative balance. Apparently, even the latter may be somewhat inferior to the whole protein for maintenance purposes.

No explanation is apparent for the above observations. Whether proteins contain, or carry as a contaminant, some component which is involved in the efficient utilization of food energy or amino acids and is destroyed by hydrolysis, or whether our findings are attributable to the more rapid absorption of free amino acids, as contrasted with native proteins which are slowly digested in the alimentary tract, is not clear. If the rate of absorption were the critical factor, one might anticipate a considerable loss of amino acids in the urine. Our experience does not warrant that conclusion. Possibly the casein, which was a commercial 'vitamin-free' product, may have carried an adsorbed agent which was not present in the liver concentrate used as a source of the less well-defined vitamins. Tests will be undertaken shortly to determine whether vitamin B₁₂ influences the caloric requirements of our subjects.³

Since the above comparisons were made, the practice has been followed in the quantitative experiments of administering 55 calories per kilo of body weight per day. Lower intakes might have sufficed in some instances. However, the

higher values avoided prolonged adjustment periods. Generally, balance was established within three or four days. Occasionally, somewhat larger intakes were found necessary. This was true of tall, slender individuals who were underweight for their height. One subject who was receiving 55 calories per kilo complained of hunger, and was permitted to increase the fuel value of his ration to 58 calories per kilo.

One may be warranted in asking whether the high energy content of the diets influenced the outcome of the investigations. To this question a categorical answer cannot be given. The necessity of using diets of higher than normal caloric content is demonstrated by the data in table 2, and by additional data of a similar sort not included in the present paper. Furthermore, any criticism of the techniques used in the present studies applies, with equal force, to like tests made with completely hydrolyzed proteins. As has been shown, the latter are not superior to mixtures of purified amino acids as regards the required fuel value of the diets, and have the disadvantage that one cannot be sure, in most instances, of the quantitative removal of the amino acid under investigation. Thus, one is forced to employ high caloric rations if studies of this general nature are to be pursued successfully. Despite the well known protein-sparing action of carbohydrates, it seems unlikely that the minimum requirements of the organism for individual amino acids could have been lowered significantly by the imposed experimental conditions. Even if one assumes that native proteins ordinarily carry an 'accessory factor' the function of which is to promote physiological economy in the utilization of food energy or amino acids, the absence of this factor would be expected to lead to a higher rather than a lower minimum requirement for a dietary essential. It does not seem reasonable to postulate that the absence from the ration of so important a substance, if it exists, would actually lessen the need of the body for something which it cannot manufacture.

Finally, attention should be called to the fact that the experience of others with low protein diets, as contrasted with diets containing amino acids, has led to the use of relatively high caloric intakes. In describing an experiment in which egg protein furnished approximately 95 per cent of the nitrogen, Murlin, *et al.* (11) state that the total energy value at the beginning of the test was placed at 45 calories per kilo of body

³There are reasons for suspecting that in the preparation of our liver concentrates from Wilson's 'liver powder 1-20' much of the vitamin B₁₂ may have been lost.

weight, "but when in individual cases it became apparent that this allowance was not sustaining body weight it was raised to 48 cal per kilo or sometimes higher, by addition principally of carbohydrate." Comparable energy intakes were employed by Bricker, *et al* (12) in a recent study of the protein requirements of young women. One of the 10 subjects needed 50 calories per kilo to maintain body weight. Our young men were encouraged to avoid unusual physical exertion during the course of the tests. However, as graduate students they found it necessary to work long hours in the laboratory, for the most part in a standing position. Also, they walked to and from their living quarters which frequently were located more than a mile from the campus. In the light of these facts, and the strange increase in fuel requirements associated with amino acid diets, the caloric intakes herein employed were not so excessive as first impressions might lead one to believe.

The intricacies involved in a study of the minimum amino acid requirements have been dealt with at some length in order that the reader may be fully advised as to the exact conditions under which the findings described below were obtained. The nitrogen balance technique has its limitations, but, at the present time, it is the only procedure which can be applied to adult man for the purposes in question. Possibly, the preceding pages have over-emphasized the difficulties and imperfections. If so, this is to be preferred, in our judgment, to unwarranted simplification of a problem which is beset by many meagerly understood variables. As Mary Swartz Rose and MacLeod (13) remarked many years ago, "the search for an absolute biological constant in protein metabolism is a vain one, any so-called biological minimum is such only for a given set of conditions."

Despite what has gone before, the values obtained in the present studies are believed to approximate very closely the true minimum needs of the human species. Under the conditions specified, remarkably definite conclusions can be reached regarding the requirements of a given individual for any essential amino acid. A valid criticism of an investigation of this nature is the comparatively small number of tests that can be made in a reasonable time. Thirty-one quantitative experiments have now been completed. These represent a tremendous undertaking, extending over a period of almost four years. The data are presented with complete

confidence, but must be viewed as strictly tentative until experience demonstrates their general applicability to a much larger number of individuals.

The procedures followed in the conduct of the quantitative experiments were almost identical with those used in the qualitative tests. One difference is to be noted. In determining which amino acids are necessary dietary components, the removal of one from the food was compensated for by raising all others sufficiently to maintain the nitrogen intake at a constant level. In demonstrating the minimum requirement of the organism for a given component, all amino acids were kept at constant amounts throughout the test except the one under investigation. The latter was progressively lowered, and the nitrogen content of the ration was maintained by the addition of glycine, urea, or both. Growth studies in this laboratory (14) have shown that glycine and urea can be utilized by rats as sources of nitrogen for the manufacture of the non-essential amino acids. The two compounds were included in the human diets for a like purpose. Throughout the entire investigation, the rations furnished approximately 10 gm of nitrogen daily except during the first two or three tests of the series. In these, the food supplied 7 gm of nitrogen daily. Thus, an abundance of nitrogen was always available to the cells for synthetic uses. This is an important point, for it does not follow that nitrogen balance could be maintained with the minimum levels of the 8 essentials alone. Under the latter circumstances, the manufacture of the non-essentials by the tissues would be impossible.

One other detail of the procedure should be described. After the minimum requirement for each amino acid had been determined, twice this value was selected as the intake of the subjects in all subsequent experiments involving other amino acids. This may be rendered more intelligible by a specific illustration. The first amino acid to be investigated was tryptophan. The diet employed at the beginning of these tests supplied 1.85 gm of L-tryptophan daily. By progressively reducing the intake, the minimum level compatible with consistent positive balance was found to be 0.15 gm daily in each of two subjects. Inasmuch as the two individuals yielded identical results, it was assumed tentatively, and in spite of the remarkable low figure, that 0.15 gm represented the minimum requirement. Later events have necessitated an up-

ward revision of this value, as will be explained later

In the meantime, the question arose as to the quantity of L-tryptophan which should be included in the food in measuring the requirements of man for other amino acids. It seemed likely that twice the minimum would be a safe intake. Thus, 0.3 gm of L-tryptophan per day has been the standard in subsequent quantitative experiments, although in some tests 0.2 gm was employed successfully. A similar procedure has been followed with each amino acid as its minimum was established. Consequently, the quantitative data have been supplemented by the accumulation of evidence, in a considerable number of individuals, that twice the minima are satisfactory intakes. The latter are arbitrarily being designated as the 'recommended intakes'.

Returning for a moment to the question of the tryptophan requirement, attention is called to the fact that 31 individuals have been kept in positive nitrogen balance upon daily intakes of 0.3 gm or less. On the other hand, a recent subject has shown a minimum requirement of 0.25 gm daily. This is decidedly the highest requirement for this amino acid we have ever observed. Eleven other subjects have been kept in balance with intakes of 0.2 gm daily, although no attempt was made to establish their minimum requirements. Because of the single high value, it seems necessary to regard 0.5 gm (twice the highest minimum) as the recommended daily intake until and unless later events demonstrate that this amount is unnecessarily large.

In table 3 are summarized the minimum daily requirements and the 'recommended daily intakes' of the 8 amino acids which are necessary dietary components for the maintenance of nitrogen equilibrium in normal human subjects. Both groups of values must be regarded as strictly tentative. In the column to the extreme right is listed the number of subjects in whom each recommended intake has been shown to be satisfactory. As will be observed, the numbers are smallest for leucine and isoleucine, since these amino acids were the last for which minimum values were established.

Many tests have been made to determine the availability in the human organism of the D amino acids. The nitrogen balance technique is not sufficiently delicate to enable one to exclude the possibility that certain D amino acids may be utilized in trace amounts which are insufficient to affect the balance. On the other hand, one

can readily decide whether the D amino acids possess any practical significance in metabolism. Our data show that D- and L-methionine are equally effective in the maintenance of nitrogen equilibrium in man, and that D-phenylalanine is partially utilized although the human organism appears to be limited as to the amount of this amino acid which it can invert. Contrary to its behavior in the rat, D-tryptophan exerts no detectable influence upon nitrogen balance in man. In our experience, this is true also of acetyl-D-tryptophan despite the report to the contrary in the literature (15). The D modifications of valine, leucine, isoleucine, threonine, and lysine appear not to be available at all in human subjects.

TABLE 3 MINIMUM AND RECOMMENDED INTAKES FOR NORMAL MAN WHEN DIET FURNISHES SUFFICIENT NITROGEN FOR SYNTHESIS OF NON-ESSENTIALS (STRICTLY TENTATIVE VALUES)

AMINO ACID	MINIMUM DAILY REQUIRE- MENT	RECOM- MENDED DAILY INTAKE	SUBJECTS TESTED
	gm	gm	no
L-Tryptophan	0.25	0.5	31 ¹
L-Phenylalanine	1.10	2.2	22
L-Lysine	0.80	1.6	27
L-Threonine	0.50	1.0	19
L-Valine	0.80	1.6	23
L-Methionine	1.10	2.2	13
L-Leucine	1.10	2.2	8
L-Isoleucine	0.70	1.4	8

¹ All of these subjects have been kept in balance on 0.3 gm or less.

Finally, the reader is reminded that in the formulation of diets of low amino acid content the so-called recommended intakes, rather than the minima, should now be employed. The purpose of the former is to make allowance for any further possible variation upward in the minimum requirements of individual subjects. Such diets, to be successful, must furnish most certainly sufficient nitrogen for the synthesis of the non-essentials. This point is emphasized repeatedly in this paper because of its utmost importance. No attempt has yet been made to ascertain the minimum total nitrogen content of a diet, carrying the recommended intakes of the eight essentials, which will sustain nitrogen equilibrium. Experiments of this nature will be undertaken at an early date. The results should provide an

approximate measure of the extent to which synthetic reactions involving nitrogen occur *in vivo*. It is contemplated also in the near future to investigate the possible replacement of phenylalanine by tyrosine, and of methionine by cystine and/or choline.

As to the applications of the above findings, it may be stated that the values summarized in table 3, if typical of male adults as we believe they are, should render it practicable, for the first time, to evaluate proteins in terms of their ability to meet human needs. Hitherto, all such appraisals of proteins have been based upon animal tests. Qualitative and quantitative differences are now recognized in the amino acid requirements of man and animals. Consequently, it does not follow necessarily that estimates of nutritive quality based upon animal tests are applicable to human subjects. It should be possible, by reference to the values now made available, to predict with reasonable accuracy how much of a given protein, if its composition is known, will be required to maintain nitrogen equilibrium in the human organism, provided a sufficient supply of nitrogen to cover the synthetic needs of the cells is also included in the food. It is to be hoped that studies of this nature will be undertaken in many laboratories. In this way only can it be ascertained whether the recommended intakes herein proposed possess general applicability. Obviously, tests of this character must take into account the digestibility of the protein under investigation.

Another application relates to preparations for parenteral use. Much interest has been manifested in recent years concerning the possibility of successful intravenous alimentation in patients who temporarily are unable to consume food in the usual way. The practicability of such a procedure was suggested by the author almost 15 years ago (16), and since then has been explored in many laboratories. Much of the enthusiasm previously displayed has now vanished. This has been due in part to the adverse clinical reactions which sometimes follow the adoption of this therapeutic measure, and in part to the fact that a relatively large quantity of a protein hydrolysate must be administered in order to approach nitrogen balance. In this connection, it

should be realized that the most appropriate mixture for clinical purposes has not yet been prepared, since the prerequisite information respecting the amino acid requirements of man has not hitherto been available. With the presentation of the facts recorded in this paper it should be feasible to formulate a mixture the composition of which is adjusted to the needs of the body for each component. Such a material may prove to be the most efficient source of nitrogen yet devised for parenteral use. One disadvantage which cannot be overcome immediately, and which may have contributed to the discouraging results observed in certain quarters, is the excessive caloric requirement manifested by subjects receiving mixtures of amino acids in place of proteins. Further studies may reveal a method, or a chemical substance, which is capable of counteracting this peculiar feature of amino acid mixtures.

CHEMICAL MEASUREMENTS IN RELATION TO PHYSICAL EVIDENCE OF MALNUTRITION

GRACE A. GOLDSMITH

From the Division of Nutrition, Department of Medicine, Tulane University School of Medicine

NEW ORLEANS, LOUISIANA

As the science of nutrition has progressed, numerous methods have been evolved for the appraisal of human nutritional status. Some years ago, recognition of malnutrition depended on simple observations, such as gross evidence of loss of weight or dehydration. The demonstration that certain physical stigmata appeared when sufficient quantities of particular chemical substances were not available to the organism, led to refinement and greater specificity of diagnosis. Advances in biochemistry made possible measurement of the concentration of essential nutritive factors and their metabolites in bodily tissues and fluids. Recently, attempts have been made to delineate chemical and physical findings at various levels of nutriture in order to detect incipient malnutrition and to evaluate nutritional status.

In discussing the relationships of chemical tests to physical signs of malnutrition, it is pertinent to emphasize certain concepts of the development of nutritional deficiency. Good nutrition is associated with an abundant supply of all essential nutrients. As malnutrition develops, bodily stores of these factors are depleted, smaller quantities are available to the tissues, urinary excretion diminishes and concentration in the blood falls. Finally a critical level is reached below which metabolic defects occur and impairment of function becomes evident. As the end stage of malnutrition, cellular structure is modified and gross evidence of deficiency disease is apparent. Incipient malnutrition exists when a decrease in reserve functional capacity occurs. Chemical procedures are particularly useful in detecting early abnormalities but are applicable in all zones of nutriture. Physical stigmata occur in chronic advanced malnutrition and may persist as scars long after tissue repletion has been accomplished.

The manifestations of acute and chronic nutritive failure are somewhat different. Acute depletion causes sudden, profound biochemical and physiologic abnormalities, chronic depletion grad-

ual chemical and structural changes, with good compensation for long periods of time. Accurate diagnosis is difficult. Physical signs of malnutrition are non-specific, absence of any one of several factors may give rise to the same structural alteration, while similar tissue change may result from disease unrelated to nutritive failure. A number of the physical signs used as indices of malnutrition rest on a very tenuous foundation. Interpretation should be cautious, since normal variability is great and the question of what constitutes a departure from normal has not been settled.

The concentration of essential nutrients in blood, urine, or other bodily fluids, reflects, in general, recent dietary intake, but pathologic conditions not primarily related to nutrient supply may influence the findings. Load tests, in which a large quantity of a nutrient is administered and changes in the concentration in the blood and urine are measured, are useful in determining the degree of saturation or depletion of the tissues. Saturation, in the sense of maximal tissue concentration, indicates at least adequate nutrition, while unsaturation is a requisite in the diagnosis of malnutrition, although not synonymous with it. Findings in load tests may be misleading in the presence of extensive breakdown of tissue since release of certain nutrients may result in an increase in excretion compatible with saturation. In persons who have suffered long periods of depletion, recent access to nutrients may elevate the concentration in the blood or tissues, without restoring function or reversing pathologic changes. Few chemical or physiologic tests are available for detection of metabolic abnormalities or decreased functional reserve capacity, yet it is here that the early and readily reversible types of malnutrition should be diagnosed. Tests of metabolic derangement are often non-specific and similar abnormalities may occur from causes unrelated to nutrient supply.

The above concepts of the pathogenesis and complexities of malnutrition make it obvious that correlation between chemical measurements and physical findings will not necessarily be observed. Such lack of correlation is common, as will be pointed out in the subsequent discussion of the relationship of chemical to physical findings in specific types of malnutrition.

CALORIC DEFICIT

Caloric deficit is manifested chiefly by physical findings. In childhood, growth failure occurs, in adults, loss of weight, wasting of tissues, weakness and fatigability are the usual findings. Prolonged, severe starvation is manifested by apathy, lethargy, syncope, dry staring hair, dullness of eyes, bradycardia, hypotension, amenorrhea, sterility, and dry inelastic skin with areas of pigmentation (1). Protein deficiency is usually an associated finding and, in any event, the nitrogen balance is negative. Anemia is common, and a low-fasting blood sugar with a diminished tolerance for glucose may be present. A decrease in the basal metabolic rate occurs. Diagnosis of profound caloric deficiency is relatively simple and the severity may be judged by the percentage loss in body weight, the rapidity of such loss, and associated findings of starvation. Detection of mild caloric undernutrition is difficult. There are no adequate standards for weight in relation to height, age, bodily build and genetic potentiality. Simple procedures which will detect the extent of depletion of vital bodily tissues, as compared to fat stores, are not available.

ANEMIA

Anemia is a useful index of malnutrition in spite of its nonspecificity, and determination of the hemoglobin concentration in the blood is widely used in evaluating nutritional status. Anemia may be due to a deficiency of protein, iron or of vitamins of the B complex, notably folic acid and vitamin B₁₂. It is likewise caused by many conditions of non-nutritional origin, such as acute or chronic blood loss, infections and neoplasia. Physical evidence of chronic anemia is minimal in the early stages and diagnosis is dependent on chemical examination. Determination of the size of the red cells (mean corpuscular volume) and of the concentration of hemoglobin in the cells (mean corpuscular hemoglobin concentration) will permit differentiation of the macrocytic anemias, which are the rule in defi-

ciency of protein, folic acid and vitamin B₁₂, from the normocytic or microcytic, hypochromic anemias of iron deficiency. Physical examination aids in detecting non-nutritional causes of anemia and assists in evaluation of its severity. In profound anemia of long standing clinical signs include pallor, glossitis, dyspnea, palpitation, tachycardia, weakness, dizziness, syncope and edema.

Determination of the level of serum iron is a useful procedure in detecting anemia due to iron deficiency. In normal persons on adequate diets, the concentration of serum iron is usually greater than 70 μg per cent (2-4). Although low levels may occur in acute and chronic infections (5, 6) a concentration of less than 60 μg per cent is suggestive of iron deficiency (7). Glossitis occurs in iron deficiency anemia (8, 9) as it does in anemia due to deficiency of vitamins of the B complex, and cheilosis has been reported. These physical findings do not correlate with the type or degree of anemia but are more common in anemia of considerable chronicity.

PROTEIN DEFICIENCY

Manifestations of protein deficiency include cessation or slowing of growth, loss of weight, muscle wasting, and edema. Nitrogen balance is negative, serum proteins decrease, particularly serum albumin, and anemia may occur. The concentration of plasma proteins may remain normal for long periods of time in the presence of protein deficiency. This is due in part to hemoconcentration (10) and if the volume of the circulating plasma is determined, protein deficiency may be detected at an earlier stage. Investigations of Elman and others (11) which indicate that a decrease of one gram in total circulating serum protein represents a loss of 30 gm of tissue protein, suggest that protein deficiency is advanced before a significant drop in the concentration of serum protein occurs.

Correlation has not always been demonstrated between clinical edema and the concentration of albumin or total proteins in the serum. This is not surprising in view of the many factors which influence edema formation. During World War II mild hypoproteinemia was common in certain famine areas (12) and concentration camps (13) but close correlation between edema and the level of serum proteins was not observed. Keys *et al* failed to obtain such a correlation in studies of 34 men maintained on a European type of famine diet. Govaerts (14), who studied famine edema

in Brussels, found serum proteins to be less than normal in the majority of patients, the mean reduction being 29 per cent. The mean osmotic pressure of the serums was reduced to an even greater extent, namely, 41 per cent. Petrides (15) reported low serum protein values in children with hunger edema in Athens. Denz (16) found a significantly lower concentration of plasma proteins in German civilian internees than in normal British subjects. The degree of edema appeared to be proportional to the reduction in plasma protein concentration but considerable variation occurred. Values for plasma albumin were low (2.58 to 3.81 gm per 100 cc of plasma), but were not correlated with the degree of edema. Worsham (17) studied the relationship of hypoproteinemia to edema in women during pregnancy. Edema was present in 8 per cent of women when the serum protein level was above 6.0 gm per 100 cc, in 21 per cent when the level was between 5.5 to 6.0 gm, and in 72 per cent when the level was less than 5.5 gm.

Further studies of protein nutrition may include measurement of the excretion of individual amino acids. This may be informative as to the biologic value of dietary protein (18), as well as uncovering specific amino acid deficiency.

VITAMIN A

Chemical tests for evaluation of vitamin A nutrition include determination of the levels of vitamin A and carotene in the blood, tests of absorption of vitamin A from the intestinal tract and estimation of the vitamin A content of the liver in specimens obtained by biopsy. Physical findings in vitamin A deficiency are dryness and scaling of the skin, follicular hyperkeratosis, xerophthalmia, Bitots spots, and night blindness or lesser degrees of abnormal dark adaptation.

The normal range of values for vitamin A and carotene in the plasma has not been entirely settled. It has been suggested that the lower limit of normal be placed between 50 and 100 μ g per cent for carotene, and between 40 and 75 International Units (19-22) or 20 to 30 μ g per 100 cc (23, 24) for vitamin A. Levels of vitamin A in the blood increase with age and seasonal variations have been noted (25). When the intake of vitamin A is reduced, the concentration of carotene in the blood falls rapidly, while that of vitamin A decreases slowly. In Hartzler's experiments (26), it took 140 days of a diet low in vitamin A before a reduction in plasma level was observed. When diets high in vitamin A are administered, concen-

tration in the blood may rise before signs of deficiency disappear (27). Hsu (28) found the mean level of vitamin A in the blood to be 56 I U in healthy Chinese, 33 I U in hospital patients without clinical signs of vitamin A deficiency, and 6 I U in patients with ocular or skin lesions attributable to lack of this vitamin. Mean carotene values in the blood in these same groups were 140, 65, and 24 μ g respectively. Van Veen and Postmus (29) found very low levels of blood vitamin A in the Netherlands East Indies, with a high incidence of poor dark adaptation, xerophthalmia and blindness. In several areas mean levels varied from 27 to 77 I U in children, and from 49 to 100 I U in adults. Xerosis conjunctivae was usually apparent when values of less than 40 I U per 100 cc were encountered. J. H. Jonxis (30) found low to absent vitamin A in the blood of children in Holland. The first clinical finding observed was follicular keratosis while keratomalacia did not occur. In surveys in Tennessee and North Carolina, Anderson and Milam (31) found no correlation between the plasma level of vitamin A and clinical signs considered to be evidence of vitamin A deficiency. Harris and co-workers (32) found lower values for carotene and vitamin A in clinic patients than in normal subjects but the former had no signs of deficiency. Adamson *et al* (33) in a survey in Newfoundland, found a significant correlation between serum vitamin A levels and excess tissue in the conjunctivae in children aged 6 to 10 years, but not in other age groups. No correlation was observed between other physical signs and the concentration of vitamin A in the serum. Numerous other studies have failed to show any correlation between the level of vitamin A in the blood and thickening of the conjunctivae (34-36).

Krause *et al* (37) found no difference in the concentration of vitamin A in the blood in children with and without follicular keratosis but carotene values were lower when folliculosis was present.

A lack of correlation between levels of vitamin A in the serum and follicular keratosis was reported in a survey in Newfoundland (36). Nor El Din (38) found an average concentration of vitamin A in the blood of 40 μ g per cent in ordinary hospital patients, 20 μ g per cent in patients with cirrhosis of the liver or with diabetes, 15 μ g per cent in patients with pellagra, and traces only in 27 persons with catarrhal or obstructive jaundice. Night blindness was present in $\frac{1}{4}$ of the patients who had cirrhosis, diabetes or jaundice, in $\frac{1}{10}$ of those with pellagra. Other workers have

shown that plasma vitamin A values are decreased in many types of disease (39, 40). It has been suggested that the levels of carotene and vitamin A in the blood are an expression of liver function (41). In cirrhosis, a low concentration of vitamin A in the blood and in the liver has been reported and the rise in blood values after oral administration of vitamin A is subnormal (42-44). Clinical evidence of deficiency was not always associated with these findings. In sprue, low values for plasma vitamin A and carotene are often obtained, tolerance tests indicate poor absorption (45) and physical signs of deficiency are frequently noted.

Impairment of dark adaptation has been produced in experimental vitamin A deficiency (46, 47) and several studies of the relationship between abnormalities of dark adaptation, the concentration of vitamin A in the blood, and clinical findings have been reported. In a nutrition survey in Tennessee (48) blood values and findings in visual tests indicated a degree of deficiency comparable to that suggested by dietary intake but few signs of vitamin A deficiency were present. Hasson and Khanna (49) noted that abnormal dark adaptation occurred only when plasma vitamin A was low, but not all subjects with low values had defective adaptation. Caveness, Satterfield, and Dann (50) found only slight correlation between biophotometer readings and vitamin A levels in the blood. Bodansky, Lewis and Haig (51), in a study of infants, found that low levels of vitamin A in the plasma were associated with low stores in the liver and poor dark adaptation. They suggested that plasma levels may be a more sensitive index of deficiency than tests of dark adaptation. Pett and LePage (52) observed a relationship between visual tests and blood levels in vitamin A deficiency. In other studies, no correlation has been demonstrated between dark adaptation response and the concentration of vitamin A in the plasma (53, 54).

The above findings indicate that while some relationship exists between levels of plasma vitamin A and carotene, dark adaptation tests, and physical evidence of vitamin A deficiency, wide individual variations occur. The many diseases which affect vitamin A metabolism make evaluation of vitamin A nutrition a difficult problem.

VITAMIN B COMPLEX

Chemical measurements for a number of the vitamins of the B complex have been developed, but only for thiamine, niacin and riboflavin is

there sufficient data relating chemical findings to physical evidence of deficiency to justify discussion at this time.

Early signs of endemic vitamin B complex deficiency, and also of experimentally induced deficiency, include non-specific complaints such as decreased appetite, easy fatigability, lack of ambition and nervousness as well as personality disturbances, including irritability, moodiness, depression, vague fears, lassitude and quarrelsomeness (55). In acute experimental deficiency, outstanding manifestations are disinclination to spontaneous activity, and personality alterations of psychoneurotic type, i.e., depression, hypochondriasis and hysteria. Long before these symptoms appear, the urinary excretion of the B vitamins has fallen to low levels (56). In one study (57), the development of mental and physical changes correlated well in the individual case with a rise in pyruvate and lactate in the blood, especially in samples taken after exercise.

Nutrition surveys in Newfoundland have always shown a low intake of the B vitamins and, until recently, a high incidence of beriberi. In 1944, members of two survey groups were impressed by the apathy and lack of spontaneity of the adults, the docility and absence of play among the children (33, 58). In re-surveys in 1948, these findings had disappeared, adults were alert, children were curious, played spontaneously and required monitoring during examination (36, 59). In the interval between 1944 and 1948 the dietary supply of the B vitamins had increased. The urinary excretion of thiamine and riboflavin was much higher in 1948, than in 1944, corroborating dietary and clinical findings.

THIAMINE

Chemical tests used in evaluating thiamine nutrition have included measurement of thiamine excretion in the urine during fasting, for 24-hour periods or for several hours after the administration of an oral or parenteral test dose of this vitamin, determination of thiamine in the blood or in tissues obtained by biopsy, estimation of cocarboxylase in the blood, determination of blood pyruvic acid and of the lactate:pyruvate ratio during fasting, after exercise or following the administration of glucose.

Clinical evidence of thiamine deficiency includes polyneuritis (dry beriberi), cardiovascular disturbances and edema. In severe deficiency acute cardiac failure may occur. Anorexia is common, while neurasthenic symptoms, digestive

disturbances and constipation have been reported as early manifestations

The urinary excretion of thiamine falls rapidly when the dietary intake of this vitamin is decreased (60-67) and approaches zero when the intake is about 0.07 mg per day. Mickelsen, Caster and Keys (68) have shown that thiamine excretion is characteristic of the individual as well as being linearly related to the intake, and that excretion of pyrimin, a pyrimidine-like component of the thiamine molecule, is valuable in assaying thiamine nutrition when the dietary supply of this vitamin is low.

The urinary excretion of thiamine during fasting has been found to correlate with the average dietary intake (64, 69, 70, 71) and with the 24-hour excretion (71, 72). This determination has been suggested as a useful procedure in detecting the presence, although not the degree, of thiamine deficiency. It has been suggested that an output of zero to 4 μg in one hour during fasting is indicative of inadequate thiamine intake or chemical unsaturation (71, 73, 74). Melnick and Field found a lower fasting excretion in subjects with clinical signs of thiamine deficiency than in normal persons. Salcedo and co-workers (75), found that the fasting one-hour urinary excretion of thiamine in beriberi varied from 0 to 8.51 μg . Mean excretion was 2.85, 2.82, and 2.75 μg in frank, suggestive and doubtful cases respectively. In apparently normal subjects, excretion ranged from 0.7 to 20 μg with a mean of 5.72 ± 3.72 . The presence of symptoms and signs of deficiency, together with an excretion of 0 to 2 μg of thiamine, was considered helpful in the diagnosis of beriberi. Hou (76) found no thiamine in the urine in acute or prolonged, chronic beriberi, a low excretion (14 μg in 24 hours) in subacute or chronic beriberi of short duration. Excretion in normal persons varied from 17 to 176 μg in 24 hours.

A number of studies of experimental thiamine deficiency have been carried out. Elsom and co-workers (77) reported that 6 subjects developed clinical signs of thiamine deficiency on a dietary intake of 0.35 mg/1000 calories and excreted less than 42 μg of thiamine in the urine in 24 hours, 3 subjects on intakes above this level were without signs of deficiency and excreted 40 to 60 μg . Objective signs of deficiency included muscle tenderness and disturbance of vibratory sense. Foresight and judgment, as measured by maze tests, were affected deleteriously. One subject developed edema after 98 days on a deficient diet.

The urinary excretion was proportional to the intake and did not change with the appearance of symptoms of deficiency.

Najjar and Holt (62) gradually reduced thiamine intake to 0.128 mg/1000 calories. Urinary excretion had been at minimal levels for many months before this final reduction in diet and no further decrease in excretion occurred when signs of deficiency, i.e., neuritis and edema, appeared. Thiamine load tests, in which the 4-hour urinary excretion was measured after the intravenous injection of 1 mg, showed a decrease preceding and associated with the development of physical evidence of lack of thiamine. Symptoms never occurred when the excretion was more than 60 μg in 4 hours but were nearly always present when excretion was less than 50 μg in 4 hours.

Williams and his collaborators (61) found the first chemical evidence of thiamine deficiency to be a decrease in the 24-hour urinary excretion, followed by a decrease in excretion after an intramuscular load test of 1 mg. Almost simultaneously with the drop in test dose excretion, values for pyruvic acid in the blood, after dextrose administration, became elevated, and symptoms of fatigue, listlessness and anorexia appeared. Symptoms progressed to apathy, nausea, epigastric pain, prostration, mental confusion and paresthesias and were associated with a progressive decrease in test dose excretion to less than 100 μg and a rise in pyruvic acid in the blood. When definite evidence of polyneuropathy appeared, the output following the test dose was less than 50 μg . The load test appeared to be valid for assessment of tissue stores while the level of pyruvic acid in the blood was valid for detecting the biochemical defect of thiamine deficiency, provided other causes of abnormal elevation could be excluded. The biochemical defect developed rapidly when the intake was 0.17 mg/1000 calories, more slowly when dietary thiamine was increased to 0.22 mg/1000 calories, while with an intake of 45 mg/1000 calories, 4 of 5 subjects developed mild metabolic abnormalities and 3 of 5 subjects depletion of tissue stores.

Keys (78, 79) studied healthy adult males on various dietary levels of thiamine and found no change in work output, or in chemical tests related to carbohydrate metabolism, after 10 to 12 weeks on an intake of 0.23 mg/1000 calories, although the urinary excretion of thiamine and the test dose returns were low. When dietary thiamine was reduced to 0.185 mg/1000 calories,

the only evidence of deficiency was an elevation in the resting and post-exercise level of blood pyruvate

Foltz and associates (68) found a decrease in appetite within 3 weeks on a diet containing 0.33 to 0.38 mg of thiamine per 1000 calories. Within 4 weeks after the intake was reduced to 0.17 to 0.21 mg/1000 calories, a decrease in work output, an increase in muscle tenderness and pain, fatigue and desire for sleep, and deterioration in mental attitude, nervous stability and alertness occurred. Urinary thiamine excretion ranged from 5 to 20 μ g in 24 hours. No change occurred in blood pyruvic acid values.

Melnick (72) studied normal subjects and persons with clinical symptoms of thiamine deficiency by means of 4 different tests: 24-hour basal excretion, fasting 4-hour excretion, response to the oral administration of 5 mg of thiamine, and 4-hour excretion after parenteral administration of 350 μ g of thiamine per square meter of surface area. Good correlation was obtained between the tests. With the parenteral test dose, all the normal but none of the deficient subjects excreted more than 50 μ g of thiamine in the subsequent 4-hour period. With this same test, Blanchaer and Cameron (80) found low excretions in debilitated subjects regardless of the etiology of their condition, and larger excretions during convalescence or in subjects with minor illness. The incidence of low excretion increased with age.

Ruffin *et al* (22) reported a significant difference in the excretion of thiamine by normal persons and patients with clinical findings of mild deficiency of the B vitamins, when a test dose of 1 mg was given intramuscularly and excretion measured for 4 hours thereafter.

Johnson (73) using a 5 mg oral load test, concluded that an output of less than 20 μ g in 4 hours was subnormal as judged by nutrition surveys in troops. Goldsmith and Sarett (66), using a similar test, found that normal subjects on adequate diets excreted more than 100 μ g in 4 hours, while persons on diets containing 0.2 to 0.3 mg/1000 calories excreted an average of 58 μ g. In patients with clinical evidence of thiamine deficiency, namely, peripheral neuritis or cardiovascular disturbances with edema, the excretion was less than 80 μ g in the 4-hour period.

The thiamine content of blood has been studied by several investigators. Most of the thiamine is found in the cellular elements (81). Foltz (68) reported that the thiamine concentration tends to correspond to the character of the diet, while

Greenberg and Rinehart (82) found it to be relatively static and not easily affected by thiamine intake. Thiamine content of the leucocytes has been reported to be decreased in thiamine deficiency (83). Estimation of cocarboxylase in whole blood has been considered an unreliable method of detecting thiamine deficiency (84), but further investigation of this test seems warranted. Oldham *et al* (64) found a decrease in blood thiamine when the dietary intake was 14 mg/1000 calories. The urinary excretion during fasting and in 24 hours was low, as was the excretion after an oral test dose of thiamine. No definite signs of deficiency occurred after 59 days on this diet but 4 of 9 subjects noted severe constipation. When the intake was raised to 0.2 mg/1000 calories and maintained at this level for 47 days, blood values returned to those found prior to the experiment, as did values for excretion during fasting. However, test dose returns were further reduced, constipation increased, and certain psychologic changes developed, namely, difficulty in grasping ideas and in the ability to concentrate. These symptoms improved when the thiamine intake was raised to 0.36 mg/1000 calories, while urinary excretion increased slightly and test dose returns remained low.

Hulse (85) reported a decrease in the yeast stimulating activity of plasma and in the thiamine content of muscle in subjects maintained for 18 days on a diet containing 0.3 mg of thiamine per 1000 calories. The only clinical finding was a vague loss in 'sense of well being'. The relationship of blood levels of thiamine to definite clinical signs of deficiency (beriberi) has not been reported. Blanchaer and Cameron (80) found a significant negative correlation between blood cellular thiamine and urinary excretion of less than 90 μ g following a load test of 350 μ g per square meter of body surface. Defective renal clearance could produce such findings, which suggests caution in classifying subjects as normal or deficient solely on the basis of response to load tests.

As noted above, elevation of pyruvic acid in the blood occurs in thiamine deficiency. Since numerous other conditions can lead to a similar rise in pyruvic acid, Allibone (86) has suggested that a decrease in the level of pyruvic acid after administration of thiamine may serve as a test of 'subclinical' deficiency. Investigation by Stotz and Bessey (87) indicated that determination of the lactate-pyruvate ratio might be of assistance

in evaluating thiamine nutrition Goldsmith (88) found a change in this ratio in patients with polyneuropathy and heart disease due to thiamine deficiency, as well as in persons with physical signs suggesting deficiency of other vitamins of the B complex. Horwitt (89) has suggested that simultaneous measurement of lactic acid, pyruvic acid and glucose in the blood, after mild exercise and glucose ingestion, may prove to be a valuable procedure in detecting early thiamine deficiency. When thiamine intake was 0.2 mg daily, an apparently pathologic level was observed with this test one to four months before 'incontrovertible clinical signs of thiamine deficiency appeared.'

From the many studies of thiamine nutrition discussed above, it seems clear that 2 chemical procedures have particular merit in detecting thiamine deficiency: 1) the test suggested by Horwitt (89) in which the levels of glucose, pyruvic acid and lactic acid in the blood are measured after a metabolic load is placed on the organism, and 2) measurement of the urinary excretion after an oral or parenteral test dose of thiamine, which permits estimation of the degree of saturation or depletion of the tissues with this vitamin.

RIBOFLAVIN

Chemical measurements suggested for evaluation of riboflavin nutrition are estimation of the quantity in the blood, either in the serum or cellular elements, and determination of the urinary excretion in 24 hours, in one hour during fasting and for several hours after the oral or parenteral administration of a test dose. Clinical signs ascribed to riboflavin deficiency include corneal vascularization, seborrheic dermatitis, glossitis, cheilosis, angular stomatitis, and lesions of the vulva and scrotum. Each of these signs has been noted in conditions other than riboflavin deficiency and the specificity of the syndrome has been questioned (90). Slight changes in corneal vascularity occur in normal subjects, do not correlate with riboflavin intake and fail to respond to therapy with riboflavin (91). Although vascularizing keratitis may be due to lack of riboflavin, this sign alone is not diagnostically significant. Cheilosis, angular stomatitis and glossitis may occur in deficiency of any one of several essential nutrients and in states unrelated to inadequate nutrition. The uncertainties in clinical diagnosis render interpretation of the relationship of chemical to physical findings most difficult.

Many studies have shown that the urinary excretion of riboflavin parallels dietary intake until high levels are reached (92, 93). Excretion may be dependent in part on the protein content (94) of the diet and a high excretion may occur after several days of fasting (95). In subjects maintained on diets restricted in riboflavin, basal excretion is low as in the response to an oral or parenterally administered test dose (61, 66, 93, 96, 97). In most instances, evidence of tissue depletion has not been associated with clinical findings considered to be characteristic of riboflavin deficiency. Horwitt (89) concluded that attempts to correlate riboflavin excretion with nutritional state were of little value except as indicative of dietary intake. Recent studies have shown that the riboflavin requirement is related to body size rather than to caloric intake (98) which may explain apparently divergent conclusions in metabolic balance experiments.

Sebrell *et al* (99), who produced cheilosis, angular fissuring and slight seborrheic lesions in patients on a diet containing 0.5 mg of riboflavin per day, found a mean excretion in 24 hours of 77 μ g with no decrease in output in the presence of objective signs of deficiency. Keys' (100) subjects who received 99 mg per day showed no clinical evidence of deficiency and no change in work performance after 52 days on this regime. The urinary excretion in the last few months was about 13 per cent of the intake while the test dose excretion, which was reduced after the first week, remained fairly constant, with perhaps slight reduction at the end of the experiment. Williams (101) maintained subjects on 0.7 mg of riboflavin per day for 288 days. No clinical signs of deficiency developed but the 24-hour excretion of riboflavin was low (14% of the intake) and there was a progressive decrease in the excretion of an intraperitoneal test dose of 2 mg of sodium riboflavin. Williams' (101) subjects received a greater daily intake of riboflavin than Sebrell's and had been fortified with riboflavin prior to the experimental period. Davis and associates (93) maintained subjects on 54 mg of riboflavin daily for over 100 days. No clear evidence of riboflavin deficiency developed. Urinary excretion averaged about 80 μ g in 24 hours and 8 μ g in one hour during fasting. Only 4 per cent of a test dose of 0.2 mg per kilogram of body weight was recovered in the urine while 20 per cent was recovered in the pre-experimental period. It seems likely that prolonged depletion is necessary for signs of deficiency to become

evident in persons previously well supplied with this vitamin

No given level of riboflavin excretion can be suggested as indicative of clinical deficiency but when the dietary intake is about 0.5 mg per day, the level at which deficiency has been demonstrated, from 50 to 100 μ g is the usual output in 24 hours. This level of excretion may be present with or without physical evidence of deficiency, and no further change occurs when lesions develop.

Kark and Bean (102) found urinary riboflavin excretion, in the post-absorptive state, lower in Indian and Occidental troops and reported a higher incidence of folliculosis, corneal invasion and cheilosis in the Indian group. Hou and Dju (103) reported a daily riboflavin excretion of 100 to 200 μ g in normal Chinese, an excretion of 39 μ g in subjects with glossitis and of 27 μ g in patients with ocular lesions of riboflavin deficiency. Anderson *et al* (104), in studies in Mexico found the mean riboflavin excretion to be 0.398 ± 0.052 mg per liter in the population as a whole. Persons with angular stomatitis excreted, on an average, 0.186 ± 0.023 mg per liter.

In studies in Newfoundland, no correlation was demonstrated between clinical signs of riboflavin deficiency and urinary excretion of this vitamin either in random specimens or after a test dose had been administered (33, 36). However the mean excretion following a test dose was lower in subjects in Newfoundland than in apparently normal persons in this country (36). Goldsmith and Sarett (105) found no significant difference between normal subjects and patients with signs of vitamin B complex deficiency in 4-hour urinary excretion after an oral test dose of riboflavin. Occasionally, high excretions occurred which could not be adequately explained.

Najjar and Holt (106) placed infants on a diet devoid of riboflavin and reported a 24-hour urinary excretion of 40–50 μ g, a serum riboflavin level of 0, and a reduction in the riboflavin content of the cellular elements of blood. When 0.4 to 0.45 mg of riboflavin was given daily, the vitamin reappeared in the serum. Burch *et al* (107) showed that total riboflavin concentration in the serum decreased by 8 to 25 per cent in 4 subjects whose dietary intake of riboflavin was reduced to 0.4 mg daily for 4 days. Axelrod (108) found essentially the same riboflavin values in the blood in persons with cheilosis and conjunctivitis as in normal subjects. In a survey in Newfoundland, no correlation was demonstrated between

the level of riboflavin in the serum and glossitis, cheilosis or circumcorneal injection (36).

It is obvious that the state of saturation or depletion of the bodily tissues can be determined by chemical tests for riboflavin, but that functional and structural impairment can not be diagnosed by these measures.

NIACIN

Chemical tests for evaluation of niacin nutrition have not been very satisfactory. Niacin is excreted in the urine in several forms, and although reliable procedures are available for measuring acid-hydrolyzable niacin and N¹-methylnicotinamide, it has not been possible, until recently, to account for more than 30 to 35 per cent of the quantity of niacin administered. In 1946 Knox and Grossman (109) isolated a compound from urine, N¹-methyl-6-pyridone-3-carboxylamide, which appears to be the major excretory product of niacin. Determination of the excretion of this pyridone should assist in appraising human niacin nutrition. Unfortunately great difficulty has been encountered in developing an accurate and simple procedure for this determination and only 2 reports have been published dealing with this subject (110, 111). Other chemical tests used in studying niacin nutrition are determination of niacin and of pyridine nucleotides in the blood, particularly in the cellular elements, and of pyridine nucleotides in the tissues (112). There is a paucity of data concerning the concentration of pyridine nucleotides at various levels of nutrition. The few studies available suggest that neither the measurement of coenzymes or of niacin in the blood offers information of diagnostic importance in niacin deficiency (113–116). Nevertheless, further studies along this line may prove valuable.

The clinical diagnosis of mild niacin deficiency also presents certain difficulties. The signs which appear prior to the development of frank pellagra, with characteristic dermatitis, are glossitis, diarrhea, and certain mild psychic disturbances, all of which are non-specific. Diagnostic reliance has been placed largely on lingual abnormalities but deficiency of other B vitamins and conditions unrelated to malnutrition can produce indistinguishable lesions.

Investigation of the urinary excretion of niacin derivatives has shown that the output of freely hydrolyzable niacin varies little with changes in diet and only a slight decrease occurs in pellagra. Early work indicated a decrease in 'trigonelline'

excretion in niacin deficiency, both in a 24-hour period and for several hours after the administration of a test dose of niacinamide, but there was overlapping of findings in normal and deficient subjects (117-119). Subsequently it was shown that the excretory product of niacin was N^1 -methylnicotinamide rather than trigonelline, and several procedures were developed for determination of this metabolite. Until a procedure is developed which can be used to measure the excretion of N^1 -methyl-6-pyridone-3-carboxylamide the only biochemical measurement which can be applied in assessment of niacin nutrition is estimation of N^1 -methylnicotinamide in the urine in 24 hours, during fasting or after a test dose of nicotinamide has been administered. The relationship of findings in these tests to physical evidence of niacin deficiency has been studied in several laboratories. The intricacies of niacin metabolism make interpretation of findings extremely difficult. There is marked individual variation in the percentage of various metabolites of niacin excreted in the urine. The availability of methyl groups in the body may be a factor in this variation. Of perhaps greater importance, is the relationship between tryptophan and niacin metabolism which has been demonstrated in man as well as in experimental animals (120-121). The excretion of N^1 -methylnicotinamide (N^1 Me) appears related to the tryptophan as well as the niacin content of the diet. The administration of tryptophan to persons on normal or restricted diets leads to an increase in the excretion of N^1 Me and of a niacin compound obtained by hydrolysis with strong acid. Goldsmith and Sarett (122) have shown abnormalities in the urinary excretion of derivatives of both niacin and tryptophan in pellagra. Furthermore, when patients with pellagra were maintained on diets low in niacin and protein and were given tryptophan, improvement in mental symptoms, glossitis and dermatitis resulted. The relationship of diets high in corn to the pathogenesis of pellagra has not been completely elucidated. The low tryptophan content of corn may be the explanation but the presence of some inhibitory substance has not been ruled out.

Studies of niacin nutrition in the future must include consideration of the dietary intake of tryptophan as well as of niacin and measurement of excretion of this amino acid and its metabolites, as well as of the excretion of niacin, N^1 -methylnicotinamide and of N^1 -methyl-6-pyridone-3-carboxylamide.

The status of chemical tests used currently in determining niacin malnutrition may be briefly summarized. The excretion of N^1 Me in 24 hours usually falls to low levels in patients with pellagra and in subjects maintained on diets low in niacin and protein (120, 123, 124). Reports of normal excretion of N^1 Me on diets containing minimal quantities of niacin (125) may perhaps be explained by the tryptophan content of the diets. A low or zero excretion of N^1 Me in the urine during fasting is indicative of low niacin stores in most instances. Normal persons, however, occasionally excrete no N^1 Me in the post-absorptive state (126). A high output of N^1 Me has been reported in prolonged fasting and in diseases associated with severe muscle wasting (126, 127).

Normal subjects usually show a prompt rise in N^1 Me excretion after a test dose of nicotinamide (66, 69, 73, 95, 128). A similar rise occurs in persons who have been maintained on diets low in niacin but supplemented with tryptophan (120). Johnson (73) suggested that an excretion of less than 0.5 mg of N^1 Me, in 4 hours after an oral test dose of 50 mg of niacinamide, indicated chemical deficiency. With a similar oral test, Goldsmith and Sarett (66, 105) found the mean excretion of N^1 Me to be lower in patients with signs of vitamin B complex deficiency than in normal subjects. Perlzweig *et al* (95) administered a single dose of 100 to 500 mg of niacinamide and noted that subjects with signs suggestive of deficiency of the B vitamins excreted only about half as much N^1 Me as did normal subjects. Ruffin *et al* (22) reported that the urinary excretion of N^1 Me after a test dose of niacinamide was lower in patients with glossitis, papillary atrophy, cheilosis and peripheral neuritis than in normal individuals. The significance of these data is greatly decreased in that many persons who are hospitalized show a low excretion after a test dose of niacinamide and yet have no lesions of deficiency. More precise evaluation of niacin nutrition awaits further investigation.

VITAMIN C

Chemical tests for assessment of vitamin C nutrition include determination of the concentration of ascorbic acid in the plasma, white cell-platelet layer or whole blood, estimation of the urinary excretion during fasting and in a 24-hour period, and load tests in which changes in blood levels and/or urinary excretion are measured for varying periods of time after administration of a dose of vitamin C. Certain changes in these

chemical tests occur before the appearance of physical evidence of scurvy. In an individual whose bodily tissues are saturated with vitamin C, the 24-hour urinary excretion reflects any increase in the amount of this vitamin ingested. The excretion falls when the dietary intake is reduced but is a poor index of deficiency since in the unsaturated person most of the ascorbic acid reaching the kidney is reabsorbed (129). Although 24-hour urine excretion is not a measure of vitamin C deficiency, there is no ascorbic acid in the urine in clinical scurvy.

The plasma concentration of ascorbic acid reflects dietary intake. When 75 to 100 mg of vitamin C are included in the diet, plasma levels of 1 to 1.4 mg per 100 cc are observed, when only 15 to 25 mg are ingested, values range from 0.1 to 0.3 mg (130). When vitamin C is removed from the diet, the plasma concentration falls fairly rapidly to zero without any physical evidence of scurvy. The ascorbic acid of the white cell-platelet layer decreases more gradually and is a better index of total body concentration (131, 132). Plasma ascorbic acid levels of zero have been reported in scurvy (133-135), and also in persons without clinical signs of vitamin C deficiency. A number of pathologic states, notably infections, are associated with reduction in plasma ascorbic acid concentration.

Load tests measure the degree of saturation of the tissues with ascorbic acid. Rall and Sherry (129) found that normal subjects excreted 50 per cent of a dose of 100 mg given intravenously, while scorbutic subjects excreted less than 5 per cent.

Kadji and co workers (136) concluded that a correlation existed between the level of plasma ascorbic acid 4 hours after the intramuscular injection of 200 mg of vitamin C and clinical signs of ascorbic acid deficiency in infants. Values below 0.2 mg per cent were found in scurvy, and below 0.6 mg per cent when bodily stores were seriously depleted. Clinical evidences of scurvy were swollen, bluish or bleeding gums, sharp costochondral junctions, swollen and tender extremities, and in most instances typical x-ray changes. Numerous other load tests have been described (137-139) in which vitamin C is given orally or parenterally and the urinary excretion or blood concentration determined at intervals thereafter. Oral tests are influenced by rate of absorption from the intestinal tract, intravenous tests by the ability of the kidney to compete with other tissues when the vascular system is flooded with ascorbic

acid. A procedure suggested recently for evaluating tissue depletion is administration of an amount of ascorbic acid larger than the expected deficit (1-3 gm), orally in divided doses throughout the day, with collection of all urine for 24 hours. The quantity of the test dose retained is estimated with allowance for 25 per cent destruction. An absolute figure for tissue depletion is thus obtained (140).

Studies of induced vitamin C deficiency have been made by several groups of investigators. Crandon, Lund and Dill (141) found that plasma ascorbic acid concentration reached zero after 41 days of a vitamin C deficient diet. The white-cell-platelet layer reached zero after 121 days. The first clinical signs of scurvy, perifollicular hyperkeratotic papules over the buttocks and posterior aspects of the thighs, appeared in 132 days. Perifollicular hemorrhages and petechiae on the lower legs were noted after 161 days. No gross changes in the gums occurred, but x-ray films of the teeth showed interruptions of the lamina dura. Capillary fragility tests remained negative. In total ascorbic acid deficiency, experimental wounds healed poorly. At this time, when 1 gm of ascorbic acid was injected intravenously, the plasma level fell to zero in 5 hours.

In Farmer's (138) experiments, a diet containing 0 to 10 mg of vitamin C was administered. Plasma ascorbic acid fell to zero in 70 days while the white cell-platelet level did not reach zero until the end of the fifth month. The physical signs of ascorbic acid deficiency were hyperkeratotic papules surrounding hair follicles, poor healing of experimental wounds, and a measurable decrease in work output. No spontaneous bleeding occurred but petechiae were noted in areas of surgical manipulation. No oral pathology was noted grossly, on biomicroscopic or on x-ray examination. Depletion must apparently be more protracted for characteristic changes in the gums or atrophy of alveolar bone with loosening of the teeth to occur. A saturation test, which consisted of measuring the blood concentration and urinary excretion of ascorbic acid at hourly intervals for 5 hours after the administration of 15 mg of ascorbic acid per kilogram of body weight, proved to be a reliable index of tissue depletion.

Peters *et al* (142) studied 10 subjects on a diet low in vitamin C, hyperkeratosis occurred in 17 to 21 weeks, exacerbation of acne in 22 weeks, perifollicular hemorrhages and tiny hemorrhages in the tips of the interdental papillae in 26 to 34 weeks, and poor wound healing in 36 weeks. The

gums became grossly abnormal (purplish, swollen and spongy) in 2 subjects. These two were the only ones showing gingivitis and periodontal disease before the experiment. No changes occurred in the capillary resistance test. Plasma ascorbic acid remained below 0.05 mg per cent after 5 weeks and the concentration in the white cells dropped below 1 mg/100 gm after 16 weeks. A leukocyte concentration of less than 2 mg/100 gm, on repeated analysis, was suggested as supporting the diagnosis of scurvy.

Johnson *et al* (143) found no detectable change in physical vigor in manual workers after 2 months on a diet containing no vitamin C although minimal gum changes were observed. Severe desaturation of tissues was shown by chemical measurements, including blood levels, urinary excretion and load tests.

In surveys of nutritional status, attempts have been made to determine the relationship of changes in the gums, capillary fragility, purpura or petechiae, and follicular hyperkeratosis, to vitamin C nutrition. In a number of studies (144-149) little or no correlation has been demonstrated between changes in the gums and the amount of ascorbic acid in the plasma or the degree of saturation of the tissues with vitamin C. Leeson (148) administered supplements of ascorbic acid to patients with low plasma ascorbic acid levels (mean 0.07 mg per cent) and obtained no change in hyperkeratosis, petechial hemorrhages, joint signs or gingivitis, although a marked rise in plasma ascorbic acid occurred. In a few investigations, the incidence of gingivitis appeared related to the intake of ascorbic acid or to the levels of the vitamin in the plasma (134, 150, 151, 152). Langhorne's (150) careful study showed that ascorbic acid intake influenced significantly the incidence of gum lesions where local treatment of gingivitis preceded the test period. Adamson *et al* (33) found a definite correlation between serum ascorbic acid and gum changes, particularly acute hyperemia, swelling, pain and bleeding on pressure, the correlation being marked in persons under 20 years of age. It may be noted that in experimental deficiency, changes in the gums do not occur before other evidences of scurvy.

The capillary fragility test is of no value in diagnosing vitamin C deficiency (129). No correlation was demonstrated between capillary fragility and saturation tests by Holland and co-workers (153). Likewise, no correlation was noted between follicular hyperkeratosis and the degree of unsaturation of the tissues with ascorbic acid

by Durham (154) or by Goldsmith and associates (36). In a survey in Newfoundland only a slight correlation, of questionable statistical significance, was observed between gum changes (marginal redness, swelling, recession, or atrophy of the interdental papillae) and values for serum ascorbic acid (136).

The studies noted above, and many others have shown a correlation between dietary intake of vitamin C and the concentration in the plasma or the excretion in the urine. Load tests are indicative of the degree of saturation or depletion of the tissues with respect to this vitamin. The concentration of ascorbic acid in the white cell-platelet layer of the blood is an index of tissue stores and is found to be zero prior to the appearance of physical evidence of scurvy. These findings are most useful in the diagnosis of vitamin C malnutrition but it should be emphasized that the presence of infection, burns, or the use of certain drugs, may influence ascorbic acid nutrition including the findings in chemical tests.

VITAMIN D

The chemical evaluation of vitamin D nutrition is dependent on measurement of the levels of alkaline phosphatase, of calcium and of phosphorus in the blood. There are no methods for estimation of vitamin D in materials of low potency. Normal values for alkaline serum phosphatase range from 5 to 15 Bodansky units in infants and young children and from 3 to 5 units in adults (155, 156). It has been suggested that 20 units is the upper limit of normal in premature infants (157). Phosphatase activity increases early in rickets, the rise is related to the severity of the rachitic process, and activity returns to normal when healing occurs (156-158). In mild rickets values of 20 to 30 units have been noted, in severe rickets values as high as 60 units (159) have been observed. In the age group in which rickets is prevalent and easily detected, other causes of an increase in serum phosphatase are uncommon. Klemmer (156) found a parallelism between the severity of clinical signs of rickets, particularly cranio tabes and swelling of the epiphyses, and serum phosphatase activity. Only rarely was there clinical and x-ray evidence of rickets without elevation of serum phosphatase. Determination of phosphorus in the serum is a less reliable measure of vitamin D deficiency, a reduction being noted only in severe rickets, and at times in the absence of rickets. Barnes and Carpenter (158) reported that roentgen examination and estimation of serum phosphorus fulfilled

to detect early rickets in a large percentage of cases, while good agreement was obtained between the degree of phosphatase activity and the development of clinical rickets or the rate and progress of healing. Sydow (160) found elevated phosphatase values in association with roentgenographic evidence of rickets. The level of serum calcium was unrelated to these findings. Determination of serum calcium is valuable primarily in the differential diagnosis of tetany.

The significance of elevated alkaline phosphatase values in children over 5 years of age has been questioned (161). Bessey (162) found a slight increase in certain groups of school children and suggested that determination of phosphatase activity might be useful in nutrition surveys. In view of the histological evidence of rickets reported by Follis *et al.* (163) in 46 per cent of children who died between the ages of 2 and 14, further studies of serum phosphatase in older children seem indicated. Elevation of serum phosphatase has been reported in osteomalacia.

These and other data indicate that phosphatase activity is the most sensitive index of active rickets, while skeletal abnormalities and roentgenographic changes are also useful in the diagnosis of avitaminosis D.

VITAMIN K

The detection of vitamin K deficiency depends on indirect measurements to determine the amount of prothrombin in the blood. In the absence of vitamin K, hypoprothrombinemia occurs and the blood-clotting time may be greatly prolonged. The clinical manifestation of vitamin K deficiency is hemorrhage. Vitamin K is synthesized by micro-organisms in the intestinal tract and dietary deficiency is extremely rare. Since bile salts are necessary for the absorption of this fat soluble vitamin, deficiency occurs when bile is absent from the gastrointestinal tract. It is also observed in the new born, in steatorrheas, and after the administration of certain drugs. Hypoprothrombinemia occurs in severe liver disease but in this instance is not due to vitamin K deficiency.

ciency but to disturbed liver function (164). Various methods (165-167) of determining prothrombin in the blood have been proposed. A number of variables other than prothrombin influence findings with all these procedures. Consequently, the exact concentration of prothrombin at which hemorrhagic phenomena occur can not be stated. When prothrombin activity exceeds 20 per cent of normal, hemorrhage is rarely due to deficiency of prothrombin. Studies in persons receiving therapy with dicumarol indicate that bleeding seldom occurs unless prothrombin activity is less than 10 per cent of normal (168, 169). Alexander (170) has reported that a prothrombin concentration of between 5 and 10 per cent of normal, determined by the method of Rosenfield and Tuft (171), is a reasonably safe level.

In the above discussion only the chemical measurements and physical signs commonly used in the appraisal of human nutritional status have been considered. Problems of mineral nutrition and electrolyte balance were of necessity omitted from this brief resume. Chemical tests for some of the newer vitamins have not been sufficiently correlated with physical evidence of malnutrition to be included.

Research up to the present time has shown that chemical tests are useful in reflecting recent dietary intake of a number of nutrients, in determining adequacy of body stores of several dietary factors, and in detecting early functional derangement of a few of these essential substances. The presence of certain physical signs, in conjunction with chemical findings, will permit diagnosis of specific types of malnutrition in many instances. Accurate diagnosis in nutrition, as in other fields of medicine, will always be dependent on careful evaluation of data from many sources and marked specificity of findings can not be anticipated. Future study of chemical and physical changes in various zones of nutriture should provide methods for more precise diagnosis of malnutrition, both in regard to nutrients now known to be important, and to new factors whose role in bodily economy has not yet been clarified.

ANEMIAS CAUSED PRIMARILY BY MALNUTRITION

W H SEBRELL

From the Experimental Biology and Medicine Institute, National Institutes of Health

BETHESDA, MARYLAND

I SHALL not attempt to review the older literature on this subject since I am sure it is familiar to most of this audience. Instead, I shall devote my time to a discussion of current research and the important problems which loom in the immediate future.

Advances in this field have been so rapid that I am no longer entirely sure what my title actually embraces. Research on anemia is constantly dragging nearly all anemias closer to nutrition. This is not too surprising if we think of blood as a body tissue which is constantly growing and being replaced at a rapid rate, also that it is a highly organized tissue of great complexity involved in many intricate and rapid chemical reactions. It therefore *must* be bound intimately with the nutritive factors which it must both transport and utilize.

Unfortunately, the word anemia has been very loosely used to mean a variety of defects.

Blood, being so complex, can be varied in a number of different ways. It is necessary to consider not only alterations in the number of the red blood cells, but also variations in their size, in the content of hemoglobin and in the total quantity of blood. In considering etiology, it is necessary to determine whether the disturbance is due to interference with or cessation of production, a block in maturation, increased destruction, or blood loss.

Without attempting to classify the anemias of malnutrition, they may conveniently be discussed in two groups: 1) those microcytic or normocytic anemias which accompany nutritional deficiencies, 2) the macrocytic anemias.

In the category of microcytic or normocytic anemias which accompany vitamin deficiencies, the most important are those associated with the vitamin B complex.

There is no need to discuss each of the B vitamins individually in relation to anemia. Biotin, P-amino benzoic acid and choline seem to be little concerned directly with erythropoiesis, nor

does thiamine appear to be of great importance. Riboflavin, pyridoxine, pantothenic acid and niacin are of sufficient interest to warrant some attention.

In view of the enormously complicated chemistry of the blood, it is not surprising that a number of different substances are intimately concerned in its formation and normal function, or that complex interrelationships exist. This is a field in which we are obviously just beginning to learn the fundamentals. As with other symptoms of nutritional difficulty, anemia is a non-specific end result which may occur when any one of many essential substances for formation is missing.

RIBOFLAVIN

There is much evidence of the importance of riboflavin in erythropoiesis in several species of animals. Several observers have reported anemia in dogs on riboflavin deficient diets (1-3) and have observed favorable responses to treatment with riboflavin (4). It also has been observed in rats (5, 6), swine (7), and monkeys (8, 9). The added strain of hemorrhage has helped to bring out the effect of riboflavin deficiency on erythropoiesis (3, 6). In some instances the anemia seen in riboflavin deficient animals has not responded to the administration of riboflavin (1, 10), suggesting a complex relationship with other factors or the presence of some other unrecognized deficiency. A similar situation was observed by Moore, Minnich, Vilter and Spies (11), who found that the anemia in their patients with riboflavin deficiency responded to iron alone. This usually would be regarded as proof of a concomitant iron deficiency, but the observation of Darby (12, 13) that some patients with angular stomatitis similar to that of riboflavin deficiency respond to iron therapy suggests the possibility of an iron-riboflavin relationship in erythropoiesis.

Riboflavin has, of course, been tried in pernicious anemia without effect (14). It is rather

surprising that in spite of the obvious importance of riboflavin in experimental anemias in animals there is such little evidence of any effect in man

PYRIDOXINE

Here, as in the case of riboflavin, there is much proof of an effect of pyridoxine on erythropoiesis in experimental animals. It has been observed in dogs (15-17), rats (18, 19), monkeys (20), swine (21), chicks (22), and ducks (23). In rats the added strain of hemorrhages shows the effect more clearly (19), as is the case with riboflavin. One of the very interesting observations that runs through the pyridoxine anemia literature is that once it is produced, complete remission cannot be obtained by pyridoxine unless a liver concentrate is also used (24, 20). This does not appear to be due to folic acid (20) and further strengthens the view, as with riboflavin, that there are complex interrelationships in these anemias. The work of Cartwright, Wintrobe and Humphreys (25) with swine has shown that a combined deficiency of iron and pyridoxine results in a more severe anemia than with deficiency of either alone, and that serum iron is unusually high in pyridoxine deficiency anemia. The administration of pyridoxine results in a rapid fall in plasma iron and a rapid rise in red cell count, indicating that the animal continued to absorb iron although unable to utilize it. This, I am sure, will suggest interesting possibilities for a role of pyridoxine to many members of this audience.

As complex as this possible interrelationship may seem, it is relatively simple compared to the real possibilities. Thus we see that a deficiency of pyridoxine results in a disturbed tryptophane metabolism as indicated by increased excretion of xanthurenic acid and kynurenine (26, 27). This introduces the possibility of a relationship between amino acids and anemia, as well as a role in the well known tryptophane-niacin effect which also is concerned in erythropoiesis, as will be discussed later in this paper.

In spite of all the evidence on animals, just as with riboflavin, there is no proved effect of pyridoxine on erythropoiesis in man (28, 11, 29, 30).

PANTOTHENIC ACID

In the case of pantothenic acid deficiency, as with pyridoxine, there is much evidence of an effect on erythropoiesis in experimental animals, but no good direct evidence that it is concerned in anemia in man.

Anemia in pantothenic acid-deficient animals has been observed with dogs (31), swine (32), monkeys (20), and rats (33). There is also evidence here, as with pyridoxine, that the problem is not a simple one, in that in some instances complete recovery does not follow the administration of pantothenic acid. Daft *et al.* (33) have obtained a partial explanation for this. Working with pantothenic acid-deficient rats, they found that the pantothenic acid deficiency resulted in a secondary folic acid deficiency. This was not the complete explanation, however, and there is still the likelihood of another unidentified factor being concerned.

The important point is that with pantothenic acid deficiency, as with pyridoxine deficiency, the failure to obtain a complete therapeutic result with the synthetic vitamin after the deficiency has been produced may be interpreted as indicating a probable interaction or metabolic relationship with other factors essential in erythropoiesis.

NIACIN

The complexities in the possible role of niacin in erythropoiesis make this substance especially interesting. In the case of niacin, effects have been observed both in man (34) and in experimental animals (35-37). However, the observations in man are so complicated by multiple deficiencies that no clearcut human anemia due to niacin can be recognized at this time (38). In the case of swine, the observation of Petri *et al.* (39) is of special interest. These workers found that removal of the fundus of the stomach of swine led to a loss of the anti-anemia substance from the liver, which could be prevented by nicotinic acid. This observation is of such importance, if true, that the work should be confirmed and extended.

Wintrobe *et al.* (40) have found that niacin deficiency in swine does not develop unless the diet is also poor in protein. The anemia can be corrected either by protein or niacin.

The work with niacin deficiency anemia in dogs is of especial interest (41). Handler and Featherston (42) observed anemia in dogs on three different diets deficient in niacin. They postulate that the effect of niacin deficiency is through deficiency in cozymase since niacin functions as a constituent of pyridine nucleotides.

One interesting aspect of niacin deficiency anemia in dogs is based on the observation of Rhoads

et al (43) 11 years ago, that on the Goldberger diet dogs were more sensitive to an anemia produced by feeding indole than were dogs on normal diets, and that this extra hemolytic effect of indole under these conditions could be abolished by liver extract. Sebrell and Hundley (44) have recently reopened this subject with some interesting results.

We have been able to show that dogs on the Goldberger diet number 123 given 500 mg of indole daily develop a severe anemia which can be corrected by the administration of 100 mg

lapse. Daily 5 mg of folic acid was then added with a third reticulocyte response to 32.8 per cent, but no rise in hematocrit or hemoglobin. The animal died shortly thereafter, apparently due to the large dose of indole (1 gm daily) (fig 2).

The second dog showed no response after 7 days of purified liver extract and had only a questionable rise in reticulocytes to 4.1 per cent. With niacin in addition to the 'Reticulogen' there was a slow response, with a reticulocyte peak of 6.9 per cent and an eventual hematocrit of 39 after 21 days.

FIG 1 EFFECT OF NIACIN on blood changes produced by indole given to a dog on Goldberger Diet No 123

of niacinamide daily, in spite of continued administration of indole (fig 1).

Although the primary factor required for response appears to be niacin, there are indications that the condition may be much more complex. Thus, there is no characteristic reticulocyte response to niacin. But 2 dogs made anemic with this technique were treated with a purified liver extract (Reticulogen) furnishing 20 units of anti-pernicious anemia factor and less than 5 mg of niacin daily. One dog showed a definite blood response with 16 per cent reticulocytes in 4 days, but relapsed. The addition of 100 mg of niacin daily gave a second response with 24.9 per cent reticulocytes, followed again by a re-

A third dog treated with 100 mg of niacinamide showed no significant response after 14 days, but reached a hematocrit of 41 in 71 days after being given 20 units of 'Reticulogen' daily while the niacin was continued.

Thus a factor present in purified liver extract containing practically no niacin appears to be involved in some of these dogs.

The possible role of tryptophane is again suggested by the fact that tryptophane is the only naturally occurring amino acid which is an indole derivative. Since there is much experimental evidence that tryptophane can be converted into niacin, 2 of the anemic dogs were treated with

tryptophane in doses of 1 gm and 2 gm of DL-tryptophane daily Neither responded favorably

Thus it appears that the indole effect is not an interference with normal tryptophane metabolism or conversion of tryptophane to niacin The

direct antagonism of indole by niacin The many questions involved offer interesting possibilities

You have no doubt noted how tryptophane has appeared in this discussion, first in connection with the anemia of pyridoxine deficiency,

FIG 2 EFFECT OF 'RETICULOGEN,' niacin and folic acid on blood changes produced by indole given to a dog on Goldberger Diet No 123

mechanism of the response to niacin is not clear Niacin may be an essential element in blood formation, and when indole given with a niacin deficient diet results in hemolytic anemia, niacin may become a limiting factor in erythrocyte formation There is also the possibility of a

and again here in connection with niacin deficiency This will be mentioned further in the discussion of amino acids

AMINO ACIDS

The production of anemia on diets low in protein is too well known to warrant review here

This really is to be expected if it is remembered that globin, a sulfur containing protein, constitutes more than 90 per cent of hemoglobin (27). The physiological importance of this is indicated by the production of blood from body protein in the anemic dog during protein deprivation (45). In spite of its importance, the complexity of the problems involved still leaves us very much in the dark as to the specific roles of the various amino acids, the presence of unidentified factors, or the metabolic interrelationship with other factors. The evidence suggests all these mechanisms.

Daft (46) found that rats on a 4 per cent casein diet failed to grow and became anemic, leukopenic and granulocytopenic. Such animals showed a leucocyte and granulocyte response following treatment either with folic acid, vitamin B₁₂, or with at least one other factor in liver. He obtained a complete response following treatment with extra protein or the essential amino acids. The deficiency condition could be prevented either by increasing the protein in the diet or by giving a mixture of methionine, threonine and tryptophane.

These observations suggest several important possible interactions, and the mechanism by which the low protein diet results in a blood dyscrasia accompanied by a deficiency or depletion of folic acid and B₁₂ is not clear. Daft's data support the view that these vitamins may be synthesized from the amino acids in the animal and that this relation between amino acids and vitamins may account for the findings. His data show that although methionine, tryptophane, and threonine have preventive action, they alone are of little value in treatment. The simultaneous administration of folic acid, PABA or of isoleucine, valine, and histidine corrected the dyscrasia in a large proportion of the experimental animals. It appears that folic acid may be synthesized in animal tissue under these conditions.

Wintrobe *et al* (27) have shown in swine that a diet apparently deficient only in protein resulted in anemia which responded to folic acid. Shehata and Johnson (47) have fed rats a low protein diet containing sulfathalidine and have shown that the incidence of anemia under these conditions depends on the level of protein in the diet.

Daft (46) has suggested the possibility that amino acid imbalance or protein deficiency may be concerned in some human blood dyscrasias.

There are old clinical observations suggesting that tyrosine metabolism is concerned in human pernicious anemia (48-50). Recent work by Swendsen *et al* (51) based on the excretion of phenols in this disease supports this viewpoint. The fact that folic acid, pyridoxine, and ascorbic acid deficiencies all affect tyrosine metabolism (52-54) and are all concerned in experimental anemias is also suggestive.

Other work of considerable interest in this connection is that of Pontes and Thivolle (55), who have observed therapeutic benefit in some cases of pernicious anemia from the administration of histidine and tryptophane. Although Robschert-Robbins *et al* (56) have shown that no one amino acid is the essential one in erythropoiesis, it does not necessarily follow that they are all of equal importance. We have recently obtained some interesting results in this field and the data which I shall now present has not been previously reported.

Young albino rats were fed a protein free basal ration for 5 days while being subjected to severe hemorrhage by a technique previously described (57). On the fifth day the protein free ration is replaced by a test ration differing only in that mixtures of amino acids replace an equal weight of dextrose. The mixture of amino acids used was based on the 10 essential ones for rat growth (58, 59). One diet contained all 10 amino acids. The other diets differed only in the omission of the indicated amino acid. Results in table 1 are given on 10 rats in each group which survived 10 days on the diet. Although only the results on hematocrit values are given in the table, hemoglobin and red cell determinations gave values which agree with the hematocrit figures. These observations with those on serum protein will be reported elsewhere in more detail. The findings are most interesting in that they indicate that absence from the diet of any of the amino acids essential for growth except arginine causes some interference with blood regeneration under these conditions. However, the variation in the effect of the omission of the various amino acids is of greater interest. It is apparent that the omission of valine or histidine most seriously handicaps blood regeneration. On the valine free diet there was great difficulty in securing 10-day survivors, and we were able to include only 9 animals in this particular test. The results with the histidine deficient diet indicate the great importance of this amino acid in hemoglobin and erythrocyte production. This is to be

expected in view of the known high histidine content of hemoglobin (60, 61). It was rather surprising that dietary methionine and tryptophane deficiency resulted in such slight interference with blood regeneration. However, the important points I wish to make are that there are apparent variations in the importance of amino acids in blood formation, that valine and histidine are especially concerned, and that a dietary deficiency of any one of the 10 essential amino acids for growth, with the exception of arginine, causes some interference with blood regeneration following hemorrhage in rats on a protein free diet.

TABLE 1 AVERAGE CHANGES IN HEMATOCRIT ON AMINO ACID DIETS FOLLOWING HEMORRHAGE

DIET	AMINO ACID OMITTED	HEMATOCRIT				T
		Days		Increase in 10 days		
		0 Vol %	10 Vol %	= S D Vol %		
1305		14 2	43 8	29 6	= 2 4	
1337	Valine	15 0	29 1	14 1	= 1 3	5 0
1356	Leucine	14 1	34 6	20 5	= 2 5	2 2
1407	Tryptophane	14 9	37 7	22 8	= 2 0	1 8
1408	Histidine	14 5	22 8	8 3	= 2 7	5 2
1409	Isoleucine	14 0	39 4	25 4	= 2 0	2 2
1410	Threonine	14 4	35 9	21 5	= 1 7	2 4
1411	Methionine	14 2	39 1	24 9	= 1 8	1 3
1412	Phenylalanine	14 4	34 4	20 0	= 1 7	2 8

1414	Lysine	14 6	32 6	18 0	= 2 2	3 2

^t values of 4.0 indicate significant results 999 times in 1000 trials

VITAMIN C

The only other vitamin except those of the B complex which appears to be intimately concerned with erythropoiesis is vitamin C. Although anemia has been found in experimental animals with scurvy (62), opinion has been divided as to whether a true anemia occurs with human vitamin C deficiency (63, 64). The weight of evidence is much in favor of a role for vitamin C in erythropoiesis, which, however, may be a complex one as is the case with the other vitamins. This is indicated by the work of Dyke *et al.* (65) who observed cases of pernicious anemia which failed to respond satisfactorily to adequate doses of potent liver extract unless vitamin C was administered. These cases probably were re-

ceiving an insufficient amount of vitamin C in their diets.

Vilter has recently reported (66) observations on 26 cases of uncomplicated scurvy of which only 2 had no anemia. He concludes that vitamin C is essential for normal hematopoiesis. Some of the characteristics of the anemia suggest to him that hemolysis may be a factor and that there is also a depression of bone marrow activity.

The question of the relation of vitamin C to erythropoiesis is further complicated by the observation that a macrocytic anemia sometimes occurs in patients with vitamin C deficiency and responds to the administration of vitamin C (67). The entire problem of the mechanism of action of vitamin C in erythropoiesis seriously needs further study. This is especially suggested by the report of Woodruff and Darby (54) that tyrosine metabolism in the scorbutic guinea pig can be favorably influenced by either vitamin C or pteroylglutamic acid.

MACROCYTIC ANEMIAS

Many new opportunities for research on the macrocytic anemias have occurred as a result of the discovery of the pteroylglutamates and vitamin B₁₂. There is such intense activity and rapid progress in this field that much of what I say today may be made out of date by work reported during this meeting.

The literature on the pteroylglutamates is already enormous and would require a monograph in itself. I shall not even attempt a superficial review of such an extensive and important mass of material, but rather shall select just a few points of special current interest. The truly brilliant research involved in the discovery, isolation and synthesis of folic acid, together with the steadily growing body of knowledge concerning its physiology, has been covered in previous reviews (68-70).

It is now clear that the pteroylglutamates are essential for a variety of animals and are found widely in plants. In man they are effective therapeutic agents in sprue, in nutritional macrocytic anemia, in the macrocytic anemia of pregnancy, in the megaloblastic anemia of infancy, and in securing a hematopoietic response in pernicious anemia (71-73).

The clinical activity of the pteroylglutamates overlaps that of vitamin B₁₂, although the 2 substances are quite obviously entirely different chemically. The most important clinical differ-

ence is that the pteroylglutamates have no beneficial effect on the central nervous system lesions of pernicious anemia (74-76), although these lesions are adequately controlled by vitamin B₁₂ (77).

In spite of the demonstrated therapeutic effect of the pteroylglutamates on human macrocytic anemias, there is as yet no proof that added folic acid is needed by normal persons. Although estimates of the quantity needed have been made on the basis of excretion studies (70, 78), such estimates do not tell us much about the normal human requirement or the controlling conditions. The solution of such problems must await better knowledge of the mechanism of action and relation to other substances essential in erythropoiesis.

I have already mentioned Daft's evidence suggesting that folic acid may be synthesized by the rat. If it can be synthesized by other mammals, this observation may be of great significance. There is great research interest in the relation of folic acid to other nutrients as well as to its mechanism of action, and it has been suggested that it is concerned in the metabolism of purines and pyrimidines (79, 80).

Elvehjem and his associates have studied the relation between folic acid and niacin deficiency and anemia in the dog (81). There are many implications of importance in their observations. The recent paper of Ruegamer *et al* (82) reports on young dogs fed a niacin deficient diet plus sulfasuxidine. Niacin therapy was only partially successful. Folic acid brought about a better response to niacin, but had no effect on a macrocytic anemia which developed progressively. One USP unit of 'Reticulogen' brought about complete recovery. Other liver extracts were only partially effective unless given in combination with folic acid. There was no need for folic acid if high levels of protein were used. One of the important points in this work was that several of the dogs developed a flaccid paralysis, suggesting that these workers may be opening the way to study of the neurological changes found with some macrocytic anemias for which we now have no explanation.

One of the most interesting developments in connection with the pteroylglutamates is the synthesis and action of inhibitors or antagonists. Jukes (83) has described seven pteroylglutamic acid antagonists synthesized by different workers. Some of these compounds have proven especially

useful in acute leukemia of children, although they are toxic and must be handled with care (84).

These compounds offer important research possibilities, and, according to the metabolite-antimetabolite theory of inhibitors, offer a chance to find further substances. This also suggests the possibility of inhibitors for vitamin B₁₂, which no doubt would assist in clarifying the action of that substance.

In this connection, I would like especially to call attention to the possibilities offered by study of the macrocytic anemia due to infestation by the fish tape worm. This anemia has been reported to respond to treatment with anti-pernicious anemia liver extract. This, therefore, offers another line of approach to the etiological factors involved in the macrocytic anemias, and I am surprised that this unusual anemia has not attracted more special study of a fundamental nature. It seems quite possible that the fish tape worm may elaborate an inhibitor or antagonist, although von Bonsdorff (85) failed to obtain any evidence of such action with dried tape worm.

Cartwright *et al* (86, 87) have produced a macrocytic anemia in swine using a pteroylglutamic acid antagonist (methyl folic acid) in the presence of one USP unit of purified liver extract. There was rapid response to pteroylglutamic acid, but response to vitamin B₁₂ or purified liver extract was less than with pteroylglutamic acid. Thymine and xanthopterin had little activity and tyrosine, adenine, and uracil were inactive. Finally, we came to one of the greatest advances in the field of erythropoiesis. This was the isolation from liver of vitamin B₁₂ in 1948 by Rickes *et al* (88) and by Smith (89). This discovery has already produced a voluminous literature and stimulated research on anemia to a degree never before seen.

Vitamin B₁₂ is reported to be a red crystalline compound with a molecular weight probably between 1500-1600, containing cobalt, phosphorus, and nitrogen (90, 91). This material is now the most potent known therapeutic substance. West (92) has obtained a maximal reticulocyte response on pernicious anemia with one microgram daily, and 25 mcg once a week has resulted in normal blood counts and improvement in spinal cord lesions. Cobaltous ion in doses of 150 mg was ineffective, and 5.4 mg of thymidine was practically without effect (93).

This observation is of particular interest be-

cause of the results of bacterial studies Stokes (79) has found that with certain bacteria thymine (5-methyl uracil) may substitute for pteroylglutamic acid Prusoff, Tepley and King (94), using a medium partially deficient in pteroylglutamic acid but otherwise satisfactory for *Lactobacillus casei*, obtained a lower content of desoxyribonucleic acid without any change in the content of ribonucleic acid An excess of thymine caused a moderate rise in both desoxyribonucleic acid and ribonucleic acid

Shive *et al* (95) have shown that thymidine (thymine desoxyriboside) may substitute for liver extracts with antipernicious anemia activity and presumably the substitution was for vitamin B₁₂.

Wright (96) has found that with some lactic acid bacteria desoxyribonucleic acid, but not ribonucleic acid, may substitute for vitamin B₁₂, and has postulated that vitamin B₁₂ functions in the conversion of thymine to thymidine

Frommeyer and Spies (97) have shown a hematopoietic effect in human macrocytic anemia from large doses of thymine, and Spies *et al* (98) report successfully treating macrocytic anemias in relapse first with thymine, on second relapse with folic acid, and on third relapse with vitamin B₁₂, thus indicating the overlapping of these widely different substances therapeutically, but in very greatly differing doses On the basis of the massive doses of thymine used by Spies, it is quite possible that the failure of thymidine in West's hands may have been due to the relatively small dose It will be interesting to see the results when larger amounts can be tested

There is considerable evidence that vitamin B₁₂ is identical with at least one animal protein factor (99-101) Further work will be required to determine whether the essential chick growth factor concentrated from fish products by Pensack, Bethke and Kennard (102) is identical with vitamin B₁₂

Although vitamin B₁₂ is effective in controlling pernicious anemia, nutritional macrocytic anemia and sprue (98), Bethell *et al* (103) have reported a case of macrocytic anemia of pregnancy which did not respond to vitamin B₁₂ but did respond to intramuscular pteroylglutamic acid It is not yet clear whether this is an unusual case similar to the few cases of sprue and pernicious anemia which fail to respond to pteroylglutamic acid, or whether vitamin B₁₂ will prove to be ineffective in this type of macrocytic anemia Lubby (104),

studying the megaloblastic anemia of infancy which responds to pteroylglutamic acid, failed to secure a response with vitamin B₁₂ alone and suggests that both vitamin B₁₂ and folic acid are normally involved in the protein metabolism of blood formation.

Bethell *et al* (105) have made the interesting observation that the feces of normal persons and of pernicious anemia patients in relapse contains a substance which promotes the growth of test organisms for vitamin B₁₂ in approximately the same amount Furthermore, he has produced a significant response in patients with pernicious anemia by injecting an extract of feces from patients with untreated pernicious anemia These findings suggest that one of the factors in pernicious anemia may be an inability to absorb vitamin B₁₂, or that vitamin B₁₂ is produced by bacterial action in the intestine and is unavailable for absorption

Castle (106) reports that gastric juice potentiates the effect of oral vitamin B₁₂, but the activity is not as great as when vitamin B₁₂ is given intramuscularly without gastric juice Vitamin B₁₂ and extrinsic factor may be identical, and the action of the intrinsic factor may be to promote absorption of vitamin B₁₂ rather than to act upon the extrinsic factor in food

Thus the availability of vitamin B₁₂ has, by moving us ahead, presented a multitude of opportunities to solve new problems It is leading rapidly to further studies of the metabolism of nucleic acids

It is a tribute to the alertness of the planners of the Federation Meetings that a symposium on the chemistry and metabolism of nucleic acids and their constituents was held at the 1947 meeting (107) when the possible importance of this subject in the anemias could not be clearly foreseen

The activity of ventriculin still must be explained, and finally, there is the possibility of additional new factors—such as the vitamin B₁₄ which Norris and Majnarch (108) have obtained from human urine and which appears to be exceedingly potent in accelerating bone marrow proliferation This substance does not contain cobalt Hays (109) has obtained evidence of another factor in liver affecting *in vitro* red blood cell maturation which he believes is not vitamin B₁₂.

It is clear that the field is broad, progress rapid and that much remains to be explained.

IVORY PAWN IN THE IVORY TOWER¹

MICHAEL HEIDELBERGER

*From the College of Physicians and Surgeons, Columbia University
and the Presbyterian Hospital*

NEW YORK CITY

UNTIL recently it was the privilege of the scientist to hold himself aloof from the mundane cares and problems of the business man, the politician, the diplomat and the soldier, and to pursue his butterfly, his gene, his diplococcus, or his macromolecule relatively undisturbed by the rumblings and creakings of the outside world. But two global wars in two generations have made this isolation dangerous, if not impossible. Many of his kind have been engaged in applying his very science to more and more efficient, less and less selective methods of mass destruction. Others have brought the far ends of the earth closer by air than are our most distant cities by train, so that all the peoples of the globe are neighbors. The economic dislocations of two wars and the unrest born of them have reached into the hospital, the university, and into the laboratory of our hitherto aloof scientist. Where will the money come from for the life-blood of his work, where can he publish his data, and will they actually be speeded to the far corners of the earth, now only a few air-hours away? How much individualism, if any, shall we give up in our domestic planning?—shall there be a National Science Foundation?—how much sovereignty or international individualism shall we give up in order to avoid the unspeakable catastrophe of another war and attempt to ensure an era of fertile peace?

These problems crowd upon our scientist, for he must protect and preserve those he loves even as he must strive for the continuity of his work, so seriously threatened. I shall leave to others consideration of our internal political and economic problems and confine myself entirely to international relations, which determine whether we are to be at peace with our neighbors and can

work on in peace, or whether we are to be sucked into another war which will surely make an end to our aspirations. What do you and I know about the foreign policy of our nation or of other nations, what can you and I do to know more about these international relations, and what can you and I do to exert our influence for fair play, for justice and for peace?

You and I, as scientists, interest ourselves in our foreign policy not only as a matter of self-preservation, but also because of our duty to do so by virtue of our special training. We are accustomed to reason clearly, to balance cause and effect, to bring every resource to bear upon the elusive detail which clears up the whole mystery. Equally important, through years of practice and discipline, we have formed the habit of self-criticism, and knowing our own weaknesses and limitations, we can the more readily see those of others. Added to these attributes of maturity is an enduring patience, the knowledge of when and how to watch and listen. What better equipment could there be for a critical examination of our foreign relations?

Last September, in Paris, I spent 10 days listening to the General Assembly of the United Nations and its Political and its Social and Economic Committees, where were gathered the diplomats, the politicians, the experts and the soldiers of the nations of the world. Only rarely did I hear evidence of those qualities of the human mind which we, as scientists, admire and honor in the practice. Were we to abandon these, science could not progress and, I submit, the construction of a durable peace will be equally impossible if emotions are appealed to rather than reason, and if partisanship, the emphasis on prestige, and the unwillingness to admit fallibility are not abandoned. It is in this area that our special qualifications can make our influence felt, and

¹ Presidential Address, Detroit, April 19, 1949

there are several organizations and activities which can help us be directly useful

How many of you are members of the American Association for the United Nations? How many are members of the Foreign Policy Association? How many belong to foreign policy study groups of the League of Women Voters? These organizations publish bulletins and hold meetings which will keep us informed and provide opportunities and occasions for our active participation in the search for the quiet atmosphere of peace without which our scientific effort will be wasted and doomed. But, you say, what can you and I do, except to read books and pamphlets and answer questionnaires, even within these groups?

While the United Nations Organization is one of governments, the American Association for the United Nations represents the people of the United States in their aspirations for the United Nations. The American Association for the United Nations is a member of the World Federation of United Nations Associations, which meets every year, and where delegates from some forty national associations for the UN discuss common problems of building an alert public opinion on the UN and plan the measures they would like to see the UN take. The Federation has consultative status A, as it is called, which means that the Economic and Social Council of the United Nations and its Commissions must receive and consider its recommendations. I have been a delegate from our Association these last two years, and in this way, some of you, too, could make the influence of your scientific judgment felt. This year there were delegations from such central European countries as Czechoslovakia, Poland, Hungary, Bulgaria, and Roumania present among the others, and although some of their members were belligerent and antagonistic at the start, all of our resolutions and recommendations were, in the end, unanimously adopted in the various working commissions and at the final plenary session. Clearly, *people* of divergent views can often agree even when their *governments* fail to find a common basis for action. Two of our 1947 resolutions were unanimously adopted, with only slight modification, by the General Assembly of the United Nations when it convened in New York in the winter of 1947-8, and until one of these was considered, the General Assembly had been unable to agree upon anything. As stated at the time by Dr. Evatt, of Australia, this changed the whole atmosphere of the meeting for the better. The General Assembly, as you see,

is quick to respond to constructive popular suggestions—their implementation, which so far has rested with the individual governments, is another matter.

Now that the more moderate portion of the World Federalists has decided to work for the evolution of the United Nations into a world government there should be large areas in which cooperation of the World Federalists and the American Association for the United Nations should be feasible, including participation in the work of the World Federation of United Nations Associations.

Another international activity in which you and I can participate is the United Nations Appeal for Children, which will continue under the United Nations International Children's Emergency Fund, or UNICEF. This work was organized by Mr. Aake Ordning, of Norway, so that everyone could take part by giving food or a day's work or its equivalent, and so strive actively in a world-wide cooperative effort for the relief of suffering. We can also give aid of books, materials or funds to the Pestalozzi Village in Trogen, Switzerland, where orphans from the devastated countries, often demoralized and brutalized by their experiences, are given a quiet family life in the cultural atmospheres of their own nations while attempts are made to solve their psychological problems. The French have a similar *Ecole Médico Pédagogique* at Nivillers, Oise, for orphans of the Résistance, and this effort is desperately in need of aid.

As you see, it is not only by our membership in international scientific societies that we can promote exchanges among peoples and can help to lessen the international tensions and rivalries that have hitherto led to wars, but must be allowed to do so no longer. You and I, as scientists, have a special fitness and a special aptitude, born of long practice and tradition, for this work, and we cannot hold aloof from it without inviting forfeiture of the rights and privileges of science and our privileges as scientists. These rights and privileges are in grave danger. As immunologists we have always preferred active intervention to passive immunization. I have suggested several available vaccines—you may grasp at these or reach for others before the onset of chills and fever. Bring on the hypodermics! The time is short in which to bestir ourselves as active, thoughtful, informed, critical, yes, patriotic citizens.

Far ahead of the field

it will pay you
to investigate the
**MOST ADVANCED
AND COMPLETE**
instrument for
**Electrophoretic
analysis**

ELECTROPHORESIS APPARATUS

Exclusive Features

**NOT TO BE FOUND
ELSEWHERE**

- ▶ Most economical because of greater analytical capacity.
- ▶ Most useful for research and routine work.
- ▶ High sensitivity . . . can detect protein concentrations as low as 0.002%.
- ▶ Operates continuously regardless of atmospheric conditions, except for servicing.
- ▶ Most complete . . . includes rapid dialysis facilities, chamber for freezing and storing specimens, sealed mechanical refrigeration system, precision Schlieren optics, complete photographic facilities, and a rotatable triple diaphragm for selecting slit, bar and straightedge patterns.
- ▶ Compact . . . measures only 30 x 37 x 67 inches high. Moved about with ease.
- ▶ More convenient . . . operator works in front of the instrument. All parts at convenient heights and locations.
- ▶ Shipped ready for operation
- ▶ Accommodates semi-micro, macro, macro-preparative, adsorption, and conductivity cells.
- ▶ Engineered for long life. Components rated far beyond their normal operating requirements.

SILVER SPRING MARYLAND

Ready...

FOR ALL YOUR RADIOACTIVITY NEEDS

Why go elsewhere when all your radioactivity requirements can be fulfilled at Tracerlab? If you need radioassay equipment we can provide it whether it be a sample container or the latest in automatic counting instrumentation such as the Automatic Sample Changer. If your requirements are in the field of health physics, you can call on us for protective devices such as ionization chamber type Radiation Survey Meter, the Laboratory Monitor counting rate meter, or the Film Badge Service. Our chemical laboratories will help you with your synthesis and "hot" laboratory problems by supplying carbon-14 tagged compounds or purified radioisotopes in convenient, useable form directly from stock. Consultation and laboratory facilities are available for special problems in health physics, radioassay work, synthesis of tagged compounds, or for carrying out complete radioactivity research programs for medical, educational, government, or industrial organizations. Write for Catalog A-2 for complete information on our instruments, facilities and services.

Today's research . . . tomorrow's practice

These two books reflect the steady flow of etiologic discoveries that have been handed to medical practice during recent years by accelerated research, particularly in the fields of chemotherapy and antibiotics. Interchange of this type of knowledge has increased to the stage where an integration of this basic material can be established into general medicine.

Viral and Rickettsial Infections of Man

edited by THOMAS M. RIVERS, M.D.

Dr. Rivers and twenty-six associates present a work that reflects the growth of general knowledge of viral and rickettsial agents. It describes the role of specific antibodies in immunity and viruses. Practical information is offered on the control of human infections in the community, the identification of carriers, the role of immunization and chemoprophylaxis. 587 Pages, 77 Illustrations, 6 in color.

Bacterial and Mycotic Infections of Man

edited by RENÉ J. DUBOS, PH.D.

A companion volume, edited by René J. Dubos, Ph.D. and thirty-three associates, begins with a brief review of the role that bacteria play in diseases and a picture of the cycle of infectious processes. Then follows a short description of the individual parasite and its behavior. Finally, fundamental principles of the management of infectious diseases are established from the viewpoint of therapy. 802 Pages, 102 Illustrations, 3 in color.

DAVOL

DOUGLAS TYPE GAS BAGS

For the collection of expired air for use in metabolism tests

GAS BAGS, DOUGLAS TYPE, Davol Wedge shape, rubber lined sturdy cloth bags, for the collection of expired air by the Douglas bag method and which permit making metabolism tests outdoors or during various types of muscular exercise. The 150 and 200 liter sizes are especially useful for the newer pulmonary functional tests.

With flexible rubber connecting tube $1\frac{1}{8}$ inches outside diameter, containing side outlet tube $\frac{3}{8}$ -inch outside diameter, and with reinforced top edge and two metal grommets for attaching bag to subject, but without valves or corrugated tubing indicated in illustration.

6415

6415 Gas Bags, Douglas Type, Davol, as above described

Capacity, liters	30	60	100	150	200
Height, inches	20	23½	30	32	36
Width, inches	15	20	25	30	30
Maximum depth at bottom, inches	12	16	18	20	24
Each	25 60	33 90	42 15	60 95	73 00

6423 Stopcock T-Shape (Three Way Tap), Aluminum For use with Douglas Bag. With three grooved tubulations 2 inches long tapering from $1\frac{1}{8}$ inches to 1 inch outside diameter and stopcock plug $\frac{3}{4}$ inch bore, provided with pin stop permitting only one-quarter turn of the plug as required for preliminary breathing into outside air also for filling, closing and reopening bag for transferring air to gas meter. 16.50

MILTON O. LEE, *Managing Editor*

2101 Constitution Ave., Washington, D. C.

FEDERATION PROCEEDINGS is published quarterly by the Federation of American Societies for Experimental Biology. The *March* issue consists of the program (Part II) of the Annual Meeting of the Federation, and the Abstracts (Part I) of the papers presented at the scientific sessions. The program includes an author index. The abstracts are arranged alphabetically according to the first author and segregated as to Societies. The *June* and *September* issues contain symposia and other special papers presented at Federation meetings as selected by the Editorial Board. The *December* issue contains the membership list and other matters pertinent to the Constituent Societies of the Federation.

Price Schedule

The subscription price is \$4.50 (\$5.25 foreign) payable in advance. Single issues may be purchased, if ordered in advance, at the following prices: No. 1 (Part I, March, Abstracts), \$3.00; No. 1 (Part II, March Program), 50¢; Nos. 2 and 3 (June and September), \$1.50 an issue; No. 4 (December), \$2.00. Subscriptions and orders should be sent to the Federation of American Societies for Experimental Biology, 2101 Constitution Ave., Washington 25, D. C.

Entered as second-class matter March 16, 1942 at the Post Office at Baltimore, Maryland under the Act of August 24, 1912

NOW available for laboratory investigations MY-B-DEN

(ADENOSINE-5-PHOSPHORIC ACID, BISCHOFF)

The potentialities of this unique biochemical—prepared by Ernst Bischoff Company, Inc.—can now be more thoroughly investigated. Our newly developed method permits increased production of exceptionally pure adenosine-5-phosphoric acid and insures adequate supplies for pharmacological study and for further progress in bacteriological and biochemical research.

Adenosine 5 phosphoric acid, a purine nucleotide present in coenzymes I and II and flavin dinucleotides, is intimately associated with life processes. Also fundamental in phosphorylation reactions, this crucial compound is a vital metabolic link in energy transfer mechanisms like muscular contraction and other enzymic reactions.

Pharmacological reports indicate the applicability of MY-B-DEN to the problems of vascular disturbances, cardiovascular malfunction and the degenerative diseases. Its value in the treatment of these disorders is being elucidated by further pharmacological research projects.

Summary of Data on a Typical Preparation of MY-B-DEN
(Adenosine 5 Phosphoric Acid, Bischoff)

Source—Yeast fermentation procedures

How Supplied—Crystalline free acid

Formula— $C_{10}H_{14}N_7O_7P \cdot H_2O$

Purity—99.5%, based on adenine, ribose and phosphorus content

Molar Ratio—Adenine : ribose : phosphorus = 1.00 : 1.01 : 1.01

Position of phosphorus—Unequivocally on ribose in 5 position

Inorganic phosphorus—None present

Complete analytical data, pertaining specifically to the individual MY-B-DEN preparation released, accompanies each shipment.

The related compounds available are adenosine and guanosine.

Now Available..

FIRST isolated in the Merck Research Laboratories in 1948, clinical studies have demonstrated that Cobione* exhibits extremely high hematopoietic activity in the following conditions

★ **PERNICIOUS ANEMIA**

In uncomplicated cases and those with neurologic involvement
In patients sensitive to liver preparations

★ **NUTRITIONAL MACROCYTIC ANEMIA**

★ **CERTAIN CASES OF MACROCYTIC ANEMIA OF INFANCY**

★ **SPRUE** (tropical and nontropical)

Cobione Possesses Significant Advantages*

- It is a pure, crystalline compound of extremely high potency, and no known toxicity, when given in recommended dosage
- It is effective against all manifestations of pernicious anemia, including the neurologic manifestations
- It is effective in, and well tolerated by patients sensitive to all liver preparations
- It is effective in extremely low doses, because of its remarkably high potency
- It may be administered in precise dosage, because it is a pure, crystalline compound

*Cobione is the trade mark of Merck & Co., Inc. for its brand of Crystalline Vitamin B₁₂

COBIONE

Announcing a new, fully automatic fraction collection apparatus

*This is the new Technicon Fraction Collector,** an apparatus which will automatically collect up to 200 rigidly controlled samples of predetermined fluid volumes. Each sample may comprise any number of drops from one to four hundred. After the selected number of drops have been collected in the test tube, the carriage automatically advances to repeat the identical collection in successive samples until the whole fractionation has been completed, whereupon the machine shuts itself off.

The automatic nature of the Technicon Fraction Collector offers many important advantages. ● Since the machine will operate continuously without supervision, it can be run 24 hours a day (and over weekends) thus tripling the fractionation work output as compared with an 8-hour laboratory day. ● Personnel is released from the tedious, time-consuming operation of cutting fractions, for once the machine is set for a given operation, it carries on automatically. ● Greater resolution is achieved through the collection of numerous small fractions, rather than a few relatively large ones, so that more data become available from a given fractionation (eg a chromatogram or a fractional distillation). ● Dependable accuracy is assured, because fractionation can now be reduced to a straightforward mechanical procedure, free of the possibility of human error.

The Technicon Fraction Collector has been thoroughly tested in actual laboratory installations, where it has proven a boon to busy research staffs. *We shall be happy to send you details on request.*

Liver-stomach concentrate was discovered and evaluated in the Lilly Research Laboratories. It was given the trade-mark name 'Extralin' (Liver-Stomach Concentrate, Lilly). To this date it stands out as a most effective oral treatment for pernicious anemia. Twelve Pulvules 'Extralin' per day will produce a standard reticulocyte response in previously untreated cases in relapse. The same dose will maintain the blood picture of the average uncomplicated case at normal levels. Neurological involvement is prevented. When neural symptoms are present, progression is promptly arrested. For cases in which oral antipernicious-anemia therapy is indicated, specify Pulvules 'Extralin'. 'Extralin' may be prescribed alone or as a supplement to injectable liver extract.

AMERICAN PHYSIOLOGICAL SOCIETY

Fifty-eighth Annual Meeting

DETROIT, MICHIGAN, APRIL 18-22, 1949

(For possible corrections in any of the following abstracts see the June issue)

Experimental mitral insufficiency W E ADAMS, E B BAY and M M NEWMAN (introduced by Lester R. Dragstedt) *Dept of Medicine and Surgery, Univ of Chicago, Chicago, Ill* Recent revival of interest in surgical treatment of valvular heart disease has prompted study of the effects of pure mitral insufficiency. Thirty dogs were operated by transthoracic approach and the anterior mitral leaflet was cut with a hooked knife introduced through the left auricular appendage. Each dog was studied 4 to 5 times preoperatively at intervals of 1 to 2 months, determinations being made of cardiac output (Fick) and right ventricular and pulmonary artery pressures by right heart catheterization. Tracings were also made on a low-frequency, critically damped ballistocardiograph. Nineteen animals survived the immediate operative period, and 10 have survived 8 to 18 months to provide the present studies. All dogs have loud systolic murmurs and the heart size has increased appreciably on fluoroscopy, but no gross evidences of heart failure or obvious limitation of physical activity have developed. Cardiac output and systemic blood pressure have remained essentially unchanged. Right ventricular pressure has been elevated in most dogs to 30-40 mm Hg systolic. In 4 of the 10 dogs, diastolic pressure has risen to 5-10 mm Hg. Left auricular pressure was palpably increased at time of operation, but could not be measured in the intact animal. Contrary to expectations, the ballistocardiograph waves have shown no change in contour, and the correlation with direct Fick outputs showed no constant change. It would appear that those animals which survived operation by 2 weeks or more show no abnormality at the present time other than moderate pulmonary hypertension.

Adrenalectomy and renin proteinuria in the rat T ADDIS and ROBERT I BOYD (by invitation) *Dept of Medicine, Stanford Univ Medical School, San Francisco, Calif* In the rat the intraperitoneal

injection of 4 mgm of renin, with the pressor value of 1 U/mg, induces a variable but pronounced increase in the protein content of the urine. This increase quickly rises to a maximum and in a few hours is gone. A unique feature of this proteinuria is the excretion of fibrinogen, for in short time urine collections made soon after an injection there may form a fine network of what seems to be fibrin. Immediately after adrenalectomy, however, no proteinuria is induced by renin, and for 10 days after adrenalectomy rats maintained on sodium chloride and glucose with added B vitamins give no definite increase in protein excretion after renin. Attempts to reestablish the renin effect in adrenalectomized rats by the injection of massive doses of cortical extracts and of desoxycorticosterone acetate gave only uncertain and equivocal results. Several adrenalectomized rats responded with slight augmentation of protein excretion after renin, but these performances were not confirmed by group averages. Intermittent injection intraperitoneally of adrenalin in maximum tolerated dosage at short intervals failed to reestablish the renin effect in adrenalectomized animals. In 2 normal rats the administration of 2,4-methylpiperadyl benzodioxane (Fournand's 993) prior to the renin did not prevent nor appreciably alter the proteinuria response to renin.

Pulsatile evaporative rates from small skin areas as measured by an infra-red gas analyzer R E ALBERT and E D PALMES (introduced by A D KELLER) *Medical Dept Field Research Lab, Fort Knox, Ky* In the course of thermal balance studies, the question arose as to why the sweat rate, as measured from the whole man by an infrared gas analyzer, was pulsatile. As an approach to the problem, the original method (Palmes *Rev Sci Instr* 19 711, 1948) was modified so that measurements could be taken from relatively small skin areas. This was accomplished

by passing dry oxygen through a cup placed on the skin and then conducting the gas to the analyzer, where the concentration of the water vapor in the oxygen was determined. In this manner, continuous quantitative measurements of the evaporative rate were obtained from skin areas measuring about 20 cm². It was found that at low sweat rates, the pulses appear in bursts. At moderate rates, they occur continuously with an average frequency of 6-7 per minute, and at very high evaporative levels, both the frequency and amplitude of the pulsations are damped. The fluctuations in the evaporative rate, as determined by this method, are dependent on the variations in the amount of skin area that is wet. The 90% response time of the instrument, which is 8 seconds, limits the maximum frequency of change that can be detected. Therefore, higher frequencies of change of rate may exist. Using duplicate sets of equipment, the measurement of dissimilar, actively sweating skin areas demonstrates that the rate variations occur simultaneously. This indicates that most of the active glands are discharged at the same time, possibly by a common stimulus arising centrally.

Serum prothrombic activity and prothrombin conversion accelerator in hemophilia and thrombocytopenia BENJAMIN ALEXANDER and GRETA LANDWEHR (introduced by HERRMAN L. BLUMGART) *Medical Research Lab, Beth Israel Hospital and Dept of Medicine, Harvard Medical School, Boston, Mass.* The prothrombic activity (1-stage) of normal human serum averages 6%. Serum and plasma mixtures exhibit more activity (faster prothrombin conversion) than the sum of the components. This is referable to a conversion accelerator (spca) which evolves during coagulation, and which can be adsorbed with BaSO₄ and eluted with citrate. Sera from thrombocytopenic and hemophilic blood, or blood clotted slowly in silicone, show abnormally high prothrombic activity, in hemophilia often exceeding that of the parent plasma. Also, they cannot accelerate thrombin evolution from added prothrombin. Nevertheless, adsorption and elution of such sera yields fractions poorer in prothrombin and capable of accelerating prothrombin conversion of added prothrombin preparations. The agent can thus, in the one stage method, accelerate thrombin formation from unconsumed prothrombin in these sera, interpretable as a much higher prothrombin concentration than actually obtains. That these sera cannot accelerate conversion of additional prothrombin supplied as plasma or prothrombin fractions suggests that spca is linked to unconsumed prothrombin. By the 2 stage method, which does not measure velocity, it would have no effect. This may explain the discrepant results obtained on hemophilic serum with both procedures. Furthermore, prothrombin consumption in the coagu-

lation of hemophilic or thrombocytopenic blood computed from differences between plasma and serum prothrombic activities (1-stage) are erroneous. Spca can be separated in a fraction containing 20 mg protein from 100 cc of serum. Many physiological and biochemical properties have been delineated. It appears different from serum Agglobulin since the latter is said to be remarkably unstable in human serum whereas spca is relatively stable.

Femoral arterial pulse in aortic insufficiency ROBERT S. ALEXANDER *Dept of Physiology, Western Reserve Univ Medical School, Cleveland, Ohio.* Aortic insufficiency was produced acutely in anesthetized dogs while recording pressure pulses from the femoral artery with optical manometers. When these recordings were analyzed and compared with similar recordings obtained under other experimental conditions it was found that, 1) the high peak of systolic pressure in the femoral artery represents an augmentation of the large central aortic pulse pressure that is relatively no greater than that observed normally. 2) The sharp drop from this systolic peak does not represent aortic regurgitation, but is simply a consequence of the high systolic level attained, relatively the fall in pressure is slower than normal. 3) The only abnormal change in pulse form produced by aortic insufficiency is the disappearance of the dicrotic waves. The latter is attributed to the elimination of the aortic standing wave, primarily because the creation of an opening at the central end of the aorta during diastole destroys the resonant properties of this system. It is therefore concluded that the Corrigan pulse observed in aortic insufficiency can be explained simply in terms of present concepts of pulse dynamics without the necessity of any additional assumptions.

Changes in the clotting mechanism produced by protamine sulfate and heparin J. GARROTT ALLEN and WILLADENE EGNER (by invitation) *Dept of Surgery, Univ of Chicago, Chicago, Ill.* Changes produced in the whole blood clotting time of the normal dog are fairly standard when 0.5 mg/kg body weight of heparin is administered intravenously. The normal clotting time is spontaneously returned to normal 90 to 120 minutes after heparin injection. The whole blood clotting time was returned to normal within 3 minutes when 0.5 mg/kg body weight of protamine sulfate was administered 10 minutes after the initial heparin injection. The clotting time, in the similarly heparinized dog, can be returned to near normal with 0.25 mg/kg of protamine sulfate, although it did not reach pre-injection level for 30 or 40 minutes. There was no effect with the injection of 0.22 or less mg/kg body weight of protamine sulfate. When 1.0 mg/kg body weight of protamine sulfate was administered intravenously in normal

dogs, it protected against the subsequent injection of 0.5 mg/kg of heparin. The extent of the protection began to diminish when heparin injection was made 30 minutes or longer after the protamine injection. No protection occurred when heparin was given 90 minutes after the protamine. The effect of 0.5 mg/kg of heparin was also inhibited by the injection of 1.0 mg/kg of gelatin given 10 minutes after heparin. Gelatin given prior to heparin showed some anti-heparin action. However, when larger amounts of gelatin (1.0 gm/kg) were injected there was no immediate protection although definite protection was observed if there was a time lapse of 4 hours before injection of heparin.

Reaction of T-1824 anion and T-1824 albumin with liver slices THOMAS H. ALLEN and PETER D. ORAHOVATS (by invitation) *Dept. of Physiology, College of Physicians and Surgeons, Columbia Univ., New York, N. Y.* The affinities of liver cells for T-1824 anion and T-1824 albumin were measured in an attempt to find the mechanisms by which this blue dye escapes from the blood stream. Rat liver slices were rapidly prepared by freehand section, rinsed twice and suspended in 2.7 ml of Ringer-phosphate (pH 7.3) of low CaCl_2 concentration (0.00024 M) contained in reaction vessels of Warburg respirometers. After equilibration at 37.5°C with oxygen, 0.3 ml of 0.000176 M T-1824 was added from the sidebulb either as T-1824 anion or T-1824 albumin (dye in 2% bovine serum albumin). For controls 0.3 ml of either Ringer or albumin-Ringer was used. The initial QO_2 was 9.3 and throughout was not changed by the addition of T-1824 although the slices became visibly blue in color. At various intervals after mixing with dye the slices were removed, and the suspension fluid was centrifuged for 5 minutes. The concentration of T-1824 in the fluid was determined using a König-Martens visual spectrophotometer. The maximum optical density always remained at 605 μ for T-1824 anion and at 625 μ for T-1824 albumin. After 200 minutes in the presence of liver slices equivalent to 10 mg dry weight, the relative amount of added dye which leaves the suspension fluid is 36% for T-1824 anion and 18% for T-1824 albumin. Graphic analysis suggests that the dyeing process follows a second order reaction in which dye is sorbed thrice as rapidly from T-1824 anion as from T-1824 albumin.

Effect of extirpating the prefrontal suppressor area 8s on correct olfactory conditioned differential responses in dogs WILLIAM F. ALLEN, *Dept. of Anatomy, Univ. of Oregon Medical School, Portland, Ore.* It was reported previously that prefrontal lobectomy abolished olfactory conditioned differential foreleg responses for hundreds of tests. The purpose of this study is to localize the area. The positive and negative conditioned stimuli con-

sisted of inhalation of clove oil and asafetida. Extirpation of the cortex was accomplished by suction. It included the caudal portion of the proreus gyri and the praesylvian (orbitalis) gyri to the level of proreus sulci. In the median line the lesion extended about 5 mm rostral of the cruciate sulci and was about 3 or 4 mm wide in front of the left and right praesylvian sulci. The forelegs did not show motor symptoms following the operations and there was no injury to the lateral olfactory tracts. After the extirpations, previously acquired positive conditioned reflexes from olfactory, auditory and cutaneous stimuli, required a varying number of tests before they appeared. Correct conditioned differential responses of the foreleg from olfactory stimuli were not obtainable during 4500 to 5000 tests, which were continuous over periods of 6 months. On the other hand, correct conditioned differential responses from auditory and cutaneous stimuli were always obtainable. The chief effect of the lesion was inability to withhold foreleg flexion during a negative conditioned test or lack of correct inhibition, which occurred when area 8s was intact. A smaller ablation involving only the caudal part of the proreus gyri produced no effect on the olfactory conditioned differential responses, but like the more extensive lesion required a number of trials before the positive conditioned reflexes could be elicited.

Effect of rest intervals on maintenance of previously induced high altitude acclimatization PAUL D. ALTLAND (introduced by HEINZ SPECHT) *Laby. of Physical Biology, Exptl. Biology and Medicine Inst., National Inst. of Health, Bethesda, Md.* This investigation was made as a part of a series of studies analyzing the mechanism of acclimatization. Maximum hematocrit values (74.0–80.0%), which have been associated with increased altitude tolerance by other investigators, were induced in Sprague-Dawley rats by 4-hour daily exposures to 18,000 and 25,000 feet simulated altitudes between ages of 14 and 100 days. Following this, cessation of exposures restored normal hematocrit values in 28–35 days. When 92 hours' rest was allowed between repeated exposures normal values were attained in 45 days. With 68 hours' rest between exposures at 18,000 feet hematocrit values leveled off at approximately 56.0% in 40 days, and at 25,000 feet they leveled off at approximately 66.0% in 20 days. With 44 hours' rest between exposures at 18,000 feet, the hematocrit values leveled off at approximately 66.0% at 20 days, and at 25,000 feet at approximately 73.0% in 20 days. When daily exposures were continued maximum levels persisted throughout 25 weeks of test. Retarded growth of male rats was observed at both altitudes (approximately 30.0% at 25,000 feet, 15.0% at 18,000 feet). Control body weight levels were

regained only in the rats of the 92-hour rest group and in those in which exposures were stopped. These experiments show that relatively high hematocrit levels may be maintained by short exposures to 18,000 or 25,000 feet at 2 or 3-day intervals, but that such acclimatization is lost completely by exposure at greater intervals.

The Rorschach test as an aid to electroencephalographic analysis MARIE D AMOROSO (introduced by T C BARNES) *Dept of Electroencephalography, Hahnemann Medical College and Hospital of Philadelphia, Penna* According to Darrow (*Psychol Rev* 54 157, 1947) electroencephalography has contributed little to psychology. This is a result of the crude clinical electroencephalographic routine now prevalent in America where thousands of patients are rushed through the EEG lab by the neurologists. Physiological factors (blood sugar, vital capacity, skin temperature) are also completely ignored (*J Psychol* 22 67, 1946, *Federation Proc* 5 5, 1946, *Federation Proc* 6 74, 1947). Personality can be related to EEG (Barnes, *Federation Proc* 6 75, 1947, Wheeler, *Am Psychologist* 3 278, 1948). In patients receiving glutamic acid Wagner (*Federation Proc* 6 220, 1947) found improved Rorschach responses correlated with disappearance of abnormalities in the EEG. We have found that blocking and repetition in the Rorschach occurs with delta activity. Of 189 patients 25 had 'good' Rorschach, 8 had normal EEGs, 11 borderline, 6 abnormal EEGs, 81 'average' Rorschach had 34 normal, 22 borderline, 24 abnormal EEGs, and 83 'poor' Rorschach had 21 normal, 13 borderline, 49 abnormal EEGs. There is a tendency for 'poor' Rorschach scores to occur with abnormal EEGs, therefore the Rorschach serves as an aid in analysis when doubtful significance is found in the electrical picture.

Carbohydrate metabolism in the decerebrated rat EVELYN ANDERSON and WEBB HAYMAKER (by invitation) *National Inst of Health, Bethesda, Maryland, and Army Inst of Pathology, Washington, D C* It has been demonstrated by Claude Bernard and numerous others since his time, that piqure of the floor of the IVth ventricle or decerebration at the pontile level in rabbits and cats gives rise in less than an hour to hyperglycemia and glycosuria and that the increase in sugar is usually maintained for 3-4 hours, but may last as long as 9 hours. The decerebrated animals generally survived not more than a day or two. This communication describes the effects of decerebration on carbohydrate metabolism in rats which survived the operation 1-3 weeks. Decerebration was done at pontile and midbrain levels. Immediately following operation, blood sugar levels were determined, and a few days to 3 weeks post-operatively, glucose tolerance, insulin sensitivity, and liver and muscle

glycogen studies were carried out. At autopsy the brains were fixed in 10% formalin, and the site of the lesions determined by microscopic examination. During the first few hours after pontile decerebration there was marked hyperglycemia, following which the glucose tolerance curve became markedly elevated. The animals showed a normal sensitivity to insulin, and their capacity to store fed glucose as liver and muscle glycogen also appeared normal.

Effect of aging on the oxygen consumption of non-nucleated erythrocytes LUIS ANGELONE (by invitation) and CLIFFORD A ANGERER *Dept of Physiology, Ohio State Univ, Columbus, Ohio* Preparatory to further studies (Gonzalez and Angerer, 1947) on the respiratory metabolism of enucleated erythrocytes, it becomes necessary to study the effect of aging on isolated erythrocytes. These cells, obtained from 32-43 normal male white rats (100-150 gm) by means of cardiac punctures, were pooled, washed twice, centrifuged to constant volume, resuspended in an equal volume of Krebs' solution (pH 7.4), and stored at 2°-8°C. Suspensions were returned to room temperature (19°-25°C) for oxygenation and withdrawal of 2.5 ml into each of 3-6 respirometers. Five different blood pools were studied from the first day to varying periods of time (12-22 days). Simultaneous determinations were made of bacteria, erythrocyte counts and oxygen consumption (Warburg technique). Since the general nature of all curves are identical, save for time, data from the last blood pool are presented as typical. Beginning the day after isolation the QO_2 (dry wt) shows a progressive decrement from -0.16 mm^3 by 14, 31, 44 and 44% on 2, 4, 7 and 13 days respectively, after which a 700% increase occurs at 21 days. An unexpectedly linear decrement from 4,820,000 to 1,180,000 erythrocytes/ mm^3 occurs at 13 days. Between 7 and 13 days a relative increase in bacteria occurs and the leveling of the curve is interpreted as due, at least in great part, to this contamination.

Dietary protein and cholic acid synthesis in dogs J H ANNENEGERS, and F FRIEND (introduced by JOHN S GRAY) *Dept of Physiology, Northwestern Univ Medical School, Chicago, Ill* This study was undertaken in order to identify the factor(s) present in protein foods which is responsible for their stimulatory effect on cholic acid output. Nine cholecystostomized dogs were used, bile-urine mixtures were analyzed spectrophotometrically for cholic acid (Irvin, Johnston, and Kopola, *J Biol Chem*, 153 439, 1944). The animals were given a basal daily diet of one half can of 'Pard' alone, then 25 and 50 gm daily of crude casein, vitamin-free casein, casein hydrolysate ('Amigen'), zein, or gelatin were added. Each diet was fed for 7 days and cholic acid output determined the last 5 days. Cholic acid output in-

creased in linear fashion with the quantity of casein or zein added to the basal diet. Vitamin-free casein increased cholic acid output to a slight but significant extent. Neither casein hydrolysate nor gelatin significantly altered cholic acid excretion when added to the basal diet. These findings suggest that some factor(s) other than amino acids is necessary for the increase in cholic acid synthesis which follows feeding of protein foods.

Mechanism of the biosynthesis of propionic acid. D. S. ANTHONY, S. F. CARSON, M. KUNA, and E. F. PHARES (introduced by ALEXANDER HOLLAENDER). *Biology Division, Oak Ridge National Lab., Oak Ridge, Tenn.* Experiments on the biosynthesis of propionic acid (by *Propionibacterium pentosaceum*) from 3-carbon substrates have indicated that C_2 and C_4 compounds are intermediate. The following C^{14} labeled compounds were used as tracers: $C^{14}H_3$, $COOH$, CH_3 , $C^{14}OOH$, CH_3 , $C^{14}O$, $COOH$ and $C^{14}OOH$, CH_2 , CH_2 , $C^{14}OOH$. Three pathways from a 3-carbon substrate to propionate were indicated, namely, 1) direct conversion without breakdown of the carbon skeleton, 2) conversion through acetate and succinate, and 3) conversion through oxalacetate and succinate. Since this is an anaerobic process, the amount of propionate formed from each of the several mechanisms depends to a large extent upon the redox state of the substrate. Determination of the extent of each of the several mechanisms was calculated from the relative specific activities of the individual carbon fragments after separation and isotopic degradation of the end-products.

Effect of vagotomy on gastric secretion and emptying time in the dog. F. ANTIA (by invitation) and A. C. IYR. *Dept. of Clinical Science, Univ. of Illinois, College of Medicine, Chicago, Ill.* Secretory studies were made on 8 dogs with gastric fistulas before and after vagotomy. After collecting a 30-minute basal sample 0.1 mg/kg histamine dihydrochloride was injected subcutaneously and samples were collected every 30 minutes for 2 hours. About 10 experiments were made before vagotomy and 10 after vagotomy in each dog. The average HCl output in response to histamine after vagotomy expressed as percentage of the average prevagotomy output was 103, 77, 69, 53, 51, 47, 33, and 26 with an average of 57%.

Six of the same dogs were studied in the same fashion before and after vagotomy using 1 mg of urecholine as the secretory stimulus. The response to urecholine varied considerably both before and after vagotomy. After vagotomy the average response to urecholine expressed as a percentage of the average prevagotomy output was 140, 105, 36, 36, 34 and 12 with an average of 61%. After vagotomy no gastric secretory response occurred in any of the dogs when insulin was given intravenously (12 mg/kg). The response to dimethyl-

allyl-5-ethyl-barbituric acid was also abolished by vagotomy. The time required for 80% emptying of a test meal of 250 cc of boiled milk or 200 cc boiled milk plus 50 cc of corn oil was studied in 4 dogs. The gastric emptying time for either meal was not significantly altered by vagotomy, thus the inhibitory effect of fat was not changed by vagotomy.

Oxygen consumption of the descending aortae of adrenalectomized rats in presence of various substrates. PHYLLIS M. ARSCOTT (by invitation) and CLIFFORD A. ANGERER. *Dept. of Physiology, Ohio State Univ., Columbus, Ohio.* Young, male, white rats, weighing between 75 and 135 gm, were used in the following experiments which treat of isolated aortae and urinary bladders. The O_2 consumption (QO_2) was studied by the Fenn technique. When aortae from adrenalectomized rats were compared with those from normal rats, there was found a decrease of 28% in the QO_2 values for the former group of rats. This figure is statistically significant. There was no observable change under the same conditions for the QO_2 values for urinary bladders of the same groups of rats. The addition, respectively, of various substrates to the aortae of normal rats gave the following percentage differences in QO_2 when compared to the aortae of normal rats without substrate: glucose -9%, lactate +18%, pyruvate -21%, succinate +214%, while under the same conditions but for aortae of the adrenalectomized rats the percentage differences were as follows: glucose -11%, lactate +126%, pyruvate +19%, and succinate +171%. The net changes between the respective pairs of results were: glucose +2%, lactate +108%, pyruvate +40%, and succinate -43%. Since the urinary bladder is composed of connective and smooth muscle tissue which simulates the histology to a certain extent of the tunicae externa and media, the change of respiratory metabolism of the aorta following adrenalectomy is related to the endothelium (tunica intima) and yellow elastic tissue, or both. If this is true, then it appears that metabolism and certain well-known permeability changes of the capillary may be correlated.

Reflex respiratory and circulatory action of veratridine on cardiac, pulmonary and carotid receptors. DOMINGO M. AVIADO, JR. and ROBERT G. PONTIUS (introduced by CARL F. SCHMIDT). *Lab. of Pharmacology, Univ. of Pennsylvania, Philadelphia, Penna.* Intravenous injection of the veratrum alkaloids has been repeatedly shown to cause reflex apnea, bradycardia and hypotension by acting on receptors in the chest. Almost all previous attempts at localization of the receptors were on open-chest preparations and the observations were on the circulatory reflexes. Catheterization of the different parts of the cardio pulmonary circulation of anesthetized dogs (morphine and chloralose) has enabled the localization of the receptors responsible

for the reflex apnea. Injection of veratridine in doses of 1 microgm/kg into the left or right pulmonary artery or into the artery far out in the substance of the lungs was followed by an immediate apnea, and a hypotension and bradycardia about 5 seconds later. The apnea is due to the drug action on pulmonary receptors because cold block of the ipsilateral cervical vago sympathetic trunk eliminated the reflex apnea without noticeably changing the circulatory response. Subsequent warming was followed by the return of the apneic response to the drug. The cardiac receptors were stimulated as long as a sufficient concentration of the drug could reach the coronary artery. Although their response was predominantly circulatory, they slightly inhibit respiration. There are receptors in the carotid region, exclusive of the carotid sinus pressoreceptors, that respond to veratridine with hyperpnea, bradycardia and hypotension. The chemoreceptors sensitive to cyanide can explain the hyperpnea but not the circulatory effects.

Hyperplasia of chromaffin material in the sympathetic paraganglia of adrenalectomized rats. H BACCHUS (by invitation), A DURY, and D B YOUNG (by invitation) *Depts of Physiology, and Zoology, George Washington Univ., Washington, D C*. Histological sections of paraganglia of the coeliac and inferior cervical plexi of bilaterally adrenalectomized and sham adrenalectomized rats 3, 4, 5, 6, 7 and 9 weeks post-operatively were examined for possible alteration and compensatory changes in their chromaffin content. An intense chromaffin reaction and hyperplasia was found in the paraganglia of the adrenalectomized rats. This was not observed in the paraganglia of the sham-adrenalectomized or normal controls. The chromaffin material was diffusely distributed and showed evidence of hyperplasia and hypertrophy in the paraganglia removed from rats which were 3 and 4 weeks post-adrenalectomized. The hyperplasia assumed a concentrated and nodular character in the paraganglia of rats which were 5 through 9 weeks post adrenalectomy. These nodular areas in the paraganglia resembled adrenal medullary tissue. Such changes were not observed in the sham-adrenalectomized rats. This alteration in the chromaffin content of the paraganglia of the coeliac and cervical plexi suggest a compensatory reaction which might also be a site for the elaboration of adrenalin in adrenalectomized rats.

The effect of the bulbar facilitatory and inhibitory systems on spinal reflex activity. L M N BACH. *Dept of Physiology, School of Medicine, Tulane Univ., New Orleans*. Because of the extreme importance of the bulbar reticular formation in facilitation and inhibition of both reflexly and cortically induced movement, it seemed of interest to determine the effect of this system on various facets

of spinal reflex activity. Animals were decerebrated under ether by either the ischemic method or by a new discrete method to be described elsewhere. Kymograph recordings were made of the reflex contractions of the tibialis anticus and the gastrocnemius muscles in response to stimulation of the ipsilateral plantar and popliteal nerves and to the contralateral popliteal nerve. Coincident stimulation of the bulbar inhibitory system (which alone had no obvious effect) caused a diminution in the degree of both reflex contraction of the tibialis muscle and reflex inhibition of the gastrocnemius muscle. The amount of rebound inhibition and contraction respectively in these two muscles was considerably increased. Bulbar facilitation causes an increase in the reciprocal innervation phenomenon by enhancing the contraction of the tibialis and the inhibition of the gastrocnemius following stimulation of the contralateral popliteal nerve. Reflex after-discharge is increased also as a result of coincident bulbar facilitation. The unexpected effects of the bulbar systems on reflex inhibition may indicate that two different processes of inhibition may obtain at the motoneuron. Studies are being carried out on the effects of these systems on occlusion and fractionation and their significance in the production of spinal shock.

The effect of local cooling and heating of the finger and wrist during exposure to high ambient temperature. MORTIMER E BADER and JERE MEAD (introduced by H S BELDING). *The Quartermaster Corps, Climatic Research Lab., Lawrence, Massachusetts*. Utilizing plethysmograph cups containing salt solution bath, surrounded by a thermoregulated air stream, with thermocouples on the skin beneath the cups as well as in the bath, measurements of blood flow through finger and wrist (a 1" segment approximately 1" above the radial prominence) were made in a warm environment (32°C). Control observations were made on one arm while local cooling and heating of the two regions were carried out on the other arm.

With a bath temperature maintained at 0°C the finger skin temperature fell to and remained approximately at 7°C, but blood flow through the cooled finger did not differ significantly from base line values prior to cooling, or from the control values in the uncooled finger. Stimuli such as pain, startle and deep inspiration produced sudden diminution in blood flow through both fingers, the decrease was transient, blood flow rising rapidly to normal levels within 2 minutes. The cooled finger, however, responded with much greater diminution than did the control. Local warming (bath 44°C skin 43°C), of the finger produced no significant increase in blood flow. In the wrist, local cooling (bath 0°C skin 12°C) did produce a decrease in blood flow, warming increased the flow above base line levels.

In an individual exposed to 32°C, local thermal stimuli do not appreciably affect finger blood flow, except that cooling increases the sensitivity to some general vasoconstrictive stimuli. In the wrist, the flow is directly responsive to local temperature changes. The presence of arteriovenous shunts in the fingers may be a factor in this difference.

Renal and hormonal mechanisms of cold diuresis RICHARD A. BADER, JOHAN W. ELIOT, and DAVID E. BASS (introduced by H. S. BELDING) *The Quartermaster Corps, Climatic Research Lab, Lawrence, Massachusetts*. The mechanisms of cold diuresis have been studied by exposing men at 15°C, reclining nude except for shorts, and comparing with results of exposure at 24°–27°C, covered by blankets. Endogenous "creatinine" clearances in 9 experiments showed no significant change in glomerular filtration, and in 16 experiments there was no significant change in either endogenous "creatinine" or para-aminohippuric acid clearance, during cold diuresis. In 12 experiments there was a substantial reduction in cold diuresis during standing, as compared with reclining. In 12 experiments cold diuresis was decidedly inhibited following 15 minutes of walking.

During cold diuresis the specific gravity and chloride concentration of the urine fell as the volume rose, and each change appeared to be correlated with the previous state of hydration and chloride content of the diet. Use of an index of chloride reabsorption showed that chloride tended to be reabsorbed to a greater degree than water.

In 27 experiments three men received small intramuscular doses of either 0.15, 0.3, 0.6 or 1.2 units per kg. of pitressin at the beginning of each exposure, either cold or warm. Inhibition of cold diuresis was proportionately longer lasting following the larger doses, but even the smallest dose reduced urine flow for 1½ hours to the same small output seen in the warm exposures, with or without pitressin. The strong similarity shown between water and cold diuresis and the extreme sensitivity to pitressin constitute suggestive evidence that cold diuresis is controlled by the posterior pituitary gland.

Hepato-renal factors in circulatory homeostasis XXIII The antidiuretic action of crystalline VDM (ferritin, apoferritin) SILVIO BAEZ (by invitation), ABRAHAM MAZUR and EPHRAIM SHORR *Dept. of Medicine, Cornell Univ. Medical College, and The New York Hospital, New York City*. A previous study from this laboratory established the antidiuretic action in animals (dogs, rabbits) of partially purified hepatic VDM concentrates. The subsequent identification of hepatic VDM, as ferritin (Mazur and Shorr, *J. Biol. Chem.*, 176, 771, 1948) has made it possible to determine whether the antidiuretic effect was due to VDM or to other unidentified components of the crude concentrates. Crystalline ferritin was prepared from horse spleen

and dog liver. Experiments were carried out on rabbits and dogs. A priming dose of ferritin (500–600 gamma ferritin nitrogen) was given intravenously 5 minutes before oral hydration with 35–40 cc/kg. of water. Then, a total of 200–300 gamma/kg. of ferritin nitrogen was infused intravenously in 50 cc. of saline over 30 minutes. In control experiments, the peak of diuresis was reached in 60–90 minutes and the ingested water excreted in 180–270 minutes. With ferritin, the peak of diuresis occurred at 170–270 minutes, excretion was complete in 300–360 minutes. Doses of 50–180 gamma ferritin nitrogen were ineffective. Antidiuresis was also observed in dogs given dog liver ferritin, this excluded the possibility of non-specific effects of heterologous protein. Crystalline horse spleen apoferritin, which has identical vasodepressor effects with ferritin, exerts comparable antidiuretic action. Rabbits immunized against horse spleen ferritin failed to exhibit antidiuresis following intravenous horse spleen ferritin while antibody to ferritin was detectable in blood. The relation of the posterior pituitary to the antidiuretic action of ferritin and apoferritin will be reported.

Urinary excretion of calcium during intravenous infusion STANLEY M. BALL (by invitation) and A. V. WOLF *Dept. of Physiology and Pharmacology, Albany Medical College, Albany, N. Y.* Female dogs received continuous intravenous infusions of calcium chloride or gluconate solution (concentrations ranging from 0 to more than 20 mEq Ca per liter) at ca. 4 cc/min for 5 hours. The diuretic effects of these solutions were not significantly different from those of 5½% glucose solution (water). The plasma Ca level is not effectively regulated by renal activity alone, there being relative retention of Ca to water even when solutions less concentrated than plasma Ca were administered. Thus Ca has no clear threshold of retention and its limiting isorrheic concentration under these conditions is smaller than the normal plasma concentration of Ca. No prominent specific effects of intravenous Ca were observed on the urinary excretion of sulfate, phosphate, bicarbonate, potassium, magnesium, hydrogen ion, sodium, or chloride, although some increased urinary excretion of the latter two have been observed with toxic doses of Ca. Loads of Ca in excess of about 24 mEq in a 15 kg. dog, created within 5 hours of steady infusion, lead to vomiting. The velocity constant of excretion for Ca (minute rate of excretion per unit load) is of the order of 1×10^{-4} to $1 \times 10^{-3} \text{ min}^{-1}$, somewhat less than previously found values for chloride from sodium chloride.

Comparative evaluation of several methods for determining alveolar gas tensions in man EARL S. BARKER (by invitation), ROBERT G. PONTIUS (by invitation), DOMINGO M. AVIADO, JR. (by invitation) and CHRISTIAN J. LAMBERTSEN *Laby of*

Pharmacology, Univ of Pennsylvania, Philadelphia, Penna Simultaneous measurements of alveolar gas tensions by 4 methods and of arterial blood gas tensions by one method were made in 11 human subjects in an attempt to establish comparative values and to determine the possible existence of a direct alveolar gas sampling method which could, in the absence of a direct standard of reference, be used to provide values comparable to those obtained by indirect calculation of mean alveolar gas tensions. Blood tensions were determined by a method having a standard deviation of ± 2.0 mm Hg. Alveolar tensions were determined by the end-expiratory Haldane-Priestley technique, the automatic end-normal expiratory method, indirect calculation of effective gas tensions and sampling of the last part of each normal expiration from the tracheal bifurcation using a catheter inserted through the cricothyroid membrane.

	$p\text{CO}_2$	$p\text{O}_2$
Arterial blood	40.5	98.0
Alveolar gas		
Haldane-Priestley End Expiratory	40.7	97.9
End-normal Expiratory (tracheal)	40.5	99.7
'Effective'	40.5	100.3
End normal Expiratory (beyond mouth)	38.6	103.1

Statistical analysis revealed no significant differences among a) $p\text{CO}_2$ of blood, Haldane-Priestley and tracheal samples, b) $p\text{O}_2$ of blood and Haldane-Priestley samples, c) the alveolar $p\text{O}_2$ obtained by the 'effective', the Haldane-Priestley and the tracheal methods. All other relationships showed statistically significant differences.

Evaluation of potential thyroxine inhibitors S B BARKER and (by invitation) C E KIELY, JR, S WAWZONEK and S C WANG *Depts of Physiology and Chemistry, State Univ of Iowa, Iowa City, Iowa*. It is desirable to have procedures available for determining whether various chemical compounds are capable of interfering with the peripheral action of thyroxine in the mammalian organism. Because of the interest of this laboratory in energy metabolism, one test has centered around O_2 -consumption studies on groups of trained albino rats. Such a method enables the measurement of the effect of appropriate dosages of potential thyroxine antagonist on endogenous as well as exogenous thyroxine. Another technique takes advantage of the increased sensitivity of the animal without thyroid to small doses of estrogen. This heightened sensitivity can be depressed by injection of thyroxine. Presumably, any inhibitor of thyroxine action should restore the greater sensitivity to estrogen. Since the vaginal smear changes can be followed without damage to the animals, sacrifice is unnecessary, and the same operated rats can be used for several tests, with an adequate interval of rest. Several compounds structurally related to thyroxine have been tried, among which are the following

3,5-dibromotyrosine, 3,5-diiodotyrosine, 3,5-diiodo-4-hydroxybenzoic acid, 4-(p-methoxyphenoxy)-3,5-dibromocinnamic acid, 4-(p-methoxyphenoxy)-3,5-diiodocinnamic acid, and (furnished by Dr M J Schiffrin of Hoffmann LaRoche, Inc) N-(4-hydroxy-3,5-diiodobenzoyl)-3-(4-hydroxy-3,5-diiodophenyl)-alanine. None of these has been found by either test to show significant evidence of antagonistic effect. Some exhibit a weak thyroxine-like activity.

Quantitative method of estimating the physiological effects of deep-breathing on the electroencephalogram T C BARNES and MARIE D AMOROSO *Dept of Electroencephalography, Hahnemann Medical College and Hospital of Philadelphia, Penna*. Methods of scoring the electroencephalogram in apnea (*J Psychol* 22:67, 1946; *Federation Proc* 6:74, 1947; *J Gerontology* 3: Supplement to No. 4, p. 4, 1948) have a greater diagnostic value than crude clinical electroencephalographic procedure. Scores for abnormal waves range from -15 (most abnormal) to -2 (normal). In 276 patients these were: 15 to 19 years -7.7, 20 to 24 -5.5, 25 to 29 -4.2, 30 to 34 -5.0, 35 to 39 -3.5, 40 to 44 -2.0, 45 to 49 -2.8, 50 to 54 +0.12, 55 and over -1.7. When age and other factors are scored the index is as follows: 15 to 19 +3.0, 20 to 24 +2.2, 25 to 29 +1.9, 30 to 34 -1.4, 35 to 39 -0.76, 40 to 44 -0.77, 45 to 49 -0.33, 50 to 54 -2.0, over 55 -1.6. It is concluded that age together with physiological factors play an important part in the effect of deep breathing on the electroencephalogram and should be taken into consideration when a final analysis is made.

CO_2 pressure gradient across the placenta DONALD H BARRON *Laby of Physiology, Yale Univ School of Medicine, New Haven, Conn*. The carbon dioxide pressure gradient between the fetal and maternal sheep blood separated by the syndesmochorial (5 layer) placenta has been estimated in animals in the last third of the gestation period. The gas content of samples drawn (with the usual precautions and with animal under a spinal anesthesia) from the uterine artery, uterine vein, umbilical artery, umbilical vein, have been referred to CO_2 dissociation curves for the estimation of pressures. The results indicate that the CO_2 pressure in the uterine artery varies between 12 and 18 mm Hg whereas the pressure in the umbilical vein fluctuates between 32 and 40 mm Hg, the average pressure difference between the fetal and maternal blood appears to be about 20 mm Hg. Further, the pH of the fetal blood leaving the placenta appears to be fairly constant at 7.35-7.42, and points to the possibility that the fetal circulation through the placenta may be adjusted to regulate the pH of the blood reaching the fetal brain.

Limitations of the polarographic method of determining the oxygen tension in whole blood J

PERCY BAUMBERGER, GABOR MARKUS (by invitation) and KATHLEEN BARDWELL (by invitation) *Physiology Dept., Stanford Univ. School of Medicine, Stanford, Calif.* In 1938 Baumberger measured the O_2 tension of dilute blood polarographically in order to determine the oxygen dissociation curve of oxyhemoglobin. In 1942 Berggren (*Acta Physiol Scand.*) determined the O_2 tension of arterial blood using separated plasma for his polarographic determinations because the presence of hemoglobin interfered with the measurements. In 1947 Baumberger (*Abst. Int. Physiol. Cong., Oxford*) reported that the O_2 tension of whole blood could be determined polarographically if cyanide were added. Further work, however, has shown that cyanide leads to correct results only under very limited conditions. Whole blood gives approximately the same polarographically determinable O_2 tension as Ringer's solution exposed to the same gas, provided the hemoglobin is fully saturated. The O_2 tension must, however, be measured at an applied voltage of -1.5 vs. standard cal. elect. If measured at -0.5 Volt, cyanide must be added in low concentration to inhibit the catalytic decomposition of the electrolytically formed hydrogen peroxide. As the ratio of hemoglobin/oxyhemoglobin increases, the contribution of oxygen dissociated from oxyhemoglobin causes a difference to develop between blood and Ringer's (confirming Berggren). Factors such as pH and temperature that displace the oxygen dissociation curve affect the size of this difference and it would appear that a useful quantitative relationship can be worked out. When blood is sufficiently diluted (1:100) this discrepancy is not apparent as demonstrated by the correct oxygen dissociation curves for oxyhemoglobin obtained by a combination of spectrophotometric and polarographic determinations.

Intestinal motility and blood flow as influenced by arterial pressure. JOHN W. BEAN and M. SIDKY MOHAMED (by invitation) *Dept. of Physiology, Univ. of Michigan, Ann Arbor, Mich.* Isolated loops of dog intestine were perfused with heparinized dog blood. Sudden elevation of constant arterial pressure induced tonic contraction and augmented rhythmic contraction, lowered pressure also frequently increased tonic and rhythmic contractions for short periods initially, later decreased them. Occlusion of venous outflow while maintaining arterial pressure constant, immediately augmented tonus, rhythmic contractions, and venous pressure which was further increased by rhythmic contractions. Opening outflow after brief occlusion resulted in a temporary rapid flow above pre-occlusion rate but tonus and motility decreased. Arterial occlusion caused an immediate gradual drop in arterial pressure, a gradually diminished flow to zero, a decrease motility and tonus frequently after an initial increase. Arterial deocclusion immediately in-

creased the flow far in excess of either the preocclusion value or that following deocclusion of the vein, suggesting vascular dilatation during lowered arterial pressure. Simultaneous venous and arterial occlusion decreased arterial pressure, raised venous pressure temporarily, slightly increased motility initially then decreased it. Sudden elevation of arterial pressure by deoccluding the artery (vein still occluded) sharply increased motility and tonus, and venous pressure increased rhythmically. The records indicate, that changes in arterial and venous pressure *per se* influence intestinal motility and tonus appreciably, they also show that changing a constant arterial pressure to a slow pulsatile pressure alters gut motility by means other than blood flow changes. Shifting from constant to pulsatile pressure caused a reversible decrease in blood flow indicative of vasoconstriction.

Observations on congenital heart cases with the oxyhemograph. VIVIAN G. BEHRMANN, FRANK W. HARTMAN (by invitation), ROBERT F. ZIEGLER (by invitation) and CONRAD R. LAM (by invitation) *Depts. of Laby., Cardiology and Surgery, Henry Ford Hospital, Detroit, Mich.* Oxyhemography was employed during operations for tetralogy of Fallot (16 patients), patent ductus arteriosus (2 patients) and coarctation of the aorta (2 patients). Every tracing included the pre-anesthesia period, the induction and fluctuations occurring throughout the surgical procedure. A calibration for each O_2 saturation curve was obtained through Van Slyke analyses on at least two arterial blood samples. The effect of anesthetic agents, drugs and intravenous solutions administered during the operation on the arterial O_2 level are shown and discussed. The usefulness of the continuous blood O_2 curve as an index of the establishment of a more adequate pulmonary circulation is well illustrated. In 8 instances, preoperative and postoperative oxyhemograph studies, which included a determination of the O_2 saturation time and the effect of exercise, have been helpful in the evaluation of the congenital heart abnormalities as well as the benefit derived from surgery. These data indicate that continuous blood O_2 saturation recordings should prove valuable not only to the cardiologist but also to the surgeon and anesthesiologist in the treatment of congenital heart disease.

Digital skin temperature and blood flow relationship following change in environmental temperature. HARWOOD S. BELDING, JERE MEAD (by invitation) and MORTIMER E. BADER (by invitation) *The Quartermaster Corps Climatic Research Lab., Lawrence, Massachusetts.* Digital skin temperatures and blood flows in the terminal phalanx (venous occlusion plethysmography) were recorded on men wearing shorts and exposed for three hours in a room at $32^\circ C$, shifted abruptly to 13° ambient temperature and later returned to the $32^\circ C$ tem-

perature The subjects lay supine and were wheeled between the constant temperature rooms to obviate the effects of exercise

In the cold, blood flows decreased immediately and precipitously and usually reached values of 3% or less of the initial levels within three minutes Digital skin temperatures fell relatively less rapidly, and closely paralleled temperatures in digits in which arterial inflow was obstructed In the warm room, after cold exposures varying from 30 minutes to 2 hours, digital temperatures rose precipitously and initially paralleled temperature rises in arterially occluded digits Return of blood flow was strikingly less rapid, e g, in the first 90 minutes at 32°C following a 2 hour cold exposure, digital temperatures returned to within 20% of the control level, but blood flow was still 90% below the control level Not until 40 minutes later did the flow increase to control levels

Conclusions as to the state of digital blood flow derived from digital skin temperature alone, in other than constant ambient conditions, are limited by the fact that a change in ambient temperature may directly produce marked digital skin temperature changes independent of digital blood flow, and hence, of body heat economy

Body water compartments in man EUGENE Y BERGER (by invitation), MARCELLE F DUNNING (by invitation), BERNARD B BRODIE (by invitation), and J MURRAY STEELE *Depts of Medicine and Biochemistry, New York Univ College of Medicine, and Research Service, Third New York Univ Medical Division, Goldwater Memorial Hospital, New York, N Y* Recent measurements of body water by the dilution of deuterium oxide and of antipyrine have shown that the average percentage of water is formales about 53%, which figure is considerably lower than the generally accepted average of 70% Further, the proportion of water exhibits considerable variability The variability may be explained on a basis of fat content since measurements of specific gravity of the body have shown that fat and water content bear an inverse relationship When the extracellular fluid space as measured by bromide was subtracted from total body water space, the intracellular fluid space obtained by difference was obviously too small to be reasonable This suggested that neither bromide nor chloride was confined to extracellular water Hence, a substance whose volume of distribution was smaller than that of bromide was likely to be a closer measure of extracellular fluid Inulin was selected because it is known not to enter cells, yet passes the glomerular membrane and enters the pleural and peritoneal spaces The inulin and bromide spaces in nephrectomized dogs and in patients with poor kidney function were compared Inulin space was about half that of the bromide space Antipyrine space and inulin space were also meas-

ured simultaneously in normal human subjects, using an infusion technique previously described (*Proc Soc for Exptl Biol & Med*, 68 507, 1948) The results indicate that extracellular space constitutes about 15% and intracellular space about 40% of the body weight in normal subjects

Mechanisms of potassium excretion in the normal dog ROBERT W BERLINER, JAMES G HILTON, and THOMAS J KENNEDY, JR (introduced by JAMES A SHANNON) *Research Service, First (Columbia Univ) Division, Goldwater Memorial Hospital, and Dept of Medicine, College of Physicians and Surgeons, Columbia Univ, New York, N Y* Certain observed reciprocal relationships between sodium and potassium excretion suggest an exchange of K for Na ions, either directly or by secretion of K and reabsorption of Na with some common anion The existence of such an exchange can be demonstrated by obtaining in the urine larger amounts of secreted K than of anions which might have been secreted with it These conditions have been fulfilled in experiments where the chief urinary anion was ferro-cyanide the minimum secreted (excreted minus filtered) K exceeding, by considerable margins, the sum of chloride, bicarbonate, sulfate and phosphate Similar conclusions to be drawn from experiments in which thiosulfate was the major anion, require the additional assumption that sulfate is not secreted In experiments where Na_2HPO_4 , $\text{Na}_2\text{S}_2\text{O}_3$ or $\text{Na}_4\text{Fe}(\text{CN})_6$ is infused and K substituted for Na in the infusion, the initial effect is a marked increase in the excretion of K accompanied by a sharp rise in urinary bicarbonate and chloride excretion The increases occur while excreted K is well below that filtered Later pH and Cl excretion level off or drop while K excretion continues to rise, with Na excretion now dropping These phenomena suggest that the initial increase in K excretion is due to decreased tubular reabsorption rather than secretion

Alcohol and sucrose in the production of liver damage in rats C H BEST, W STANLEY HARTROFT (by invitation), C C LUCAS and JESSIE H RIDOUT (by invitation) *Banting and Best Dept of Medical Research, Univ of Toronto, Toronto, Canada* Although other investigators have studied the influence of alcohol upon the production of cirrhosis in several species of animals, no one, as far as we are aware, has examined the effect of isocaloric paired-feeding, i e, supplying the non-alcoholic control animals with only the same quantity of basal diet as was eaten by the animals consuming alcohol (15% solution replacing drinking water) and equalizing the caloric intake by adding an appropriate amount of carbohydrate (powdered sucrose) to the food of the controls About 200 white rats of the Wistar strain, initially weighing 150 grams, divided into 12 groups, were studied under these experimental conditions for 6 months, some being given lipotropic

supplements (choline, methionine or protein) Liver damage frequently attributed to alcohol appeared when sugar was substituted for it isocalorically The inclusion of 0.05% of choline chloride in the basal diet (casein 10, gelatin 5, zein 3, cystine 0.3, fat 12, cellulose 2 and carbohydrate, with adequate minerals and vitamins, including α -tocopherol) sufficed to prevent the appearance of more than slight fatty change in the livers of the majority of animals on the basal ration (total lipids under 15%) An adequate supply of choline, or precursors, in relation to the total caloric intake (including alcohol or sugar supplements) prevented liver damage Addition of sucrose to the basal diet produced as severe liver damage as did an isocaloric intake of alcohol, even to the point of fibrous tissue proliferation observed in a few rats This type of experiment is, at present, being carried out in very young rats and in older rats receiving diets in which the available lipotropic factors have been more drastically reduced

A phase-boundary mechanism for impulse formation, transmission and synaptic properties of nerve R. BEUTNER and T. C. BARNES *Dept. of Pharmacology, Hahnemann Medical College and Hospital of Philadelphia, Penna.* Previous reports (*Science* 94: 211, 1941) described the negative phase-boundary electrical potential of acetylcholine at the interface between oil and saline forming a wave like the nerve impulse (*Internat. Physiol. Congress* 390, 1947; *Federation Proc.* 6: 73, 1947) Our present experiments demonstrate the transmission of this wave A horizontal glass tube 60 \times 1.2 cm (paraffined to reduce conductivity over the glass surface) contains a continuous layer of guaiacol and resin mixture with a supernatant saline layer At each end of the horizontal tube there is a U-tube—one for introduction of the acetylcholine and one for the recording electrodes on each side of the oil layer The addition of 0.1 cc of saline containing 0.1 mg acetylcholine in the U-tube at one end produces a negative wave of 3 mv lasting 0.15 sec recorded from the other U-tube at the opposite end of the horizontal tube Multichannel electroencephalographic recording showed that the velocity is over 1 m per sec Conduction may be direct as between two nodes of Ranvier (*Stampfli, Internat. Physiological Congress* 218, 1947) The sensitivity of the synapse to acetylcholine was duplicated by adding more resin to the middle horizontal tube and filling the terminal U-tubes with oil only In this modified elongated oil-cell acetylcholine produced a transmitted wave when added to the ends or synapses but had no effect when added to the middle of the central tube or axon

Cortical response to light in the unanesthetized rabbit REGINALD G. BICKFORD (introduced by CHARLES F. CODE) *Section on Physiology, Mayo Foundation and Mayo Clinic, Rochester, Minn.* The

basic response of the cortex to a light flash of short duration in the unanesthetized rabbit consists of an initial fast diphasic deflection (*a*-wave) at 40 milliseconds, followed by a large 'slow and variable diphasic deflection (*b*-wave), swinging negative and then sharply positive, and delayed at its negative peak by 200 milliseconds from the flash The '*a*'-wave, enhanced in size and changed to a predominantly surface positive deflection by barbiturate narcosis, has been studied by previous workers Because of its variability and the fact that it is suppressed by barbiturate narcosis, the '*b*'-wave has received little attention Investigation has shown that the intermittency of the '*b*'-wave in the unanesthetized rabbit results from the disturbing effect of sensory stimuli Thus, the '*b*'-wave may be promptly suppressed (without affecting the '*a*'-wave) by adequate stimulation of the visual, auditory, olfactory or tactile systems The suppression cannot be maintained indefinitely by continued stimulation of one system Thus, stimuli appear to be effective in proportion to their 'surprise value' Weak sensory stimuli may cause suppression in a small part of the responding striate area It seems probable that the '*b*'-wave represents the synchronized response of neurons concerned in elaboration of visual material, receipt of which is signaled by the '*a*'-wave Arousal stimuli cause a temporary desynchronization of the former mechanism This phenomenon is of particular interest, since a similar suppression of the responses to light stimulation can be demonstrated in electro-encephalograms of human beings

Cardiac oxygen consumption and efficiency in man R. J. BING, and (by invitation), M. HAMMOND, J. HANDELSMAN, S. POWERS, and F. SPENCER *Dept. of Surgery, Johns Hopkins Univ. School of Medicine, and Johns Hopkins Hospital, Baltimore, Md.* The O_2 consumption and efficiency of human heart muscle were obtained *in vivo*, in patients with anemia, essential hypertension, coarctation of the aorta, and aortic stenosis and insufficiency Several patients were in cardiac failure resulting from mitral stenosis and insufficiency The coronary blood flow was determined with the nitrous oxide method and coronary vein blood was collected through a catheter inserted into the coronary sinus The O_2 consumed per 100 gm of left ventricular muscle was obtained from the coronary blood flow per 100 gm of cardiac tissue and the difference in O_2 content between coronary arterial and venous blood Left ventricular weight was obtained from the table of Smith, and the left ventricular efficiency was calculated from the work and the energy cost of the left ventricle Since figures for heart weight cannot be obtained accurately, values for the efficiency are approximations

In normal man the coronary flow averaged 65 cc/min/100 gm cardiac tissue, the arteriovenous

oxygen difference 11 vol %, and the O_2 consumption 7.8 cc/100 gm/min. In anemia the coronary flow was increased, the arteriovenous O_2 difference and the O_2 consumption were reduced. In essential hypertension the coronary flow was normal, the arteriovenous O_2 difference and the O_2 consumption were decreased. In coarctation the coronary flow, the arteriovenous O_2 difference, and the O_2 consumption were markedly increased. In cardiac failure the coronary flow was reduced but the arteriovenous O_2 difference was increased. The O_2 consumption was slightly above normal. As a result of these changes the cardiac efficiency was highest in essential hypertension and lowest in cardiac failure. The lowered cardiac efficiency in failure was primarily the result of decreased left ventricular work. Correlation between the work and the O_2 consumption of the left ventricle was good except in essential hypertension and cardiac failure.

Properties of the antidiuretic substance in the blood of normal and adrenalectomized rats J. H. BIRNIE (by invitation), W. J. EVERSOLE (by invitation), W. R. BOSS (by invitation), C. M. OSBORN (by invitation) and ROBERT GAUNT, *Dept. of Zoology, Syracuse Univ., Syracuse, N. Y.* It has been reported (Birnie, Jenkins, Eversole and Gaunt—in press) that the blood of normal rats contains an antidiuretic, chloruretic substance (ADS). It was readily detectable by a modified Heller and Urban assay procedure in 1 ml. quantities of fresh serum injected intraperitoneally. The serum lost its activity upon standing at 9°C. for 12 hours, and was present in greater quantities in adrenalectomized than in normal rats. The latter observation will presumably help explain the well-known failure of water diuresis in adrenalectomized animals. Newer experiments have shown the following: 1) ADS was not detected in 1 ml. samples of the serum of rats hypophysectomized from 4 to 11 days. 2) The ADS of normal rat serum (1 ml.) does not affect renal glomerular filtration as indicated by creatinine clearance tests and presumably therefore works by stimulating the tubular reabsorption of water. 3) The ADS is active when injected subcutaneously but less effective than by intraperitoneal administration. 4) Unlike the ADS, an isotonic gelatin solution, prepared for blood substitute use, has no effect on diuresis in 1 ml. doses. 5) Crude protein solutions, injected intraperitoneally, may inhibit diuresis by other mechanisms; they differ from ADS in that they act less promptly and are not chloruretic. All of these observations are consistent with the idea that the circulating ADS is the antidiuretic hormone of the posterior pituitary.

Analysis of factors affecting the assay of gastric secretory depressants D. BLICKENSTAFF (by invitation) and M. I. GROSSMAN, *Dept. of Clinical Science, Univ. of Illinois College of Medicine, Chicago, Ill.* In order to design an efficient and accurate

assay procedure, the factors which contribute to the variability of results in assaying gastric secretory depressants were studied statistically. The day to day and hour to hour variability in the output of HCl in response to small doses of histamine administered subcutaneously every 10 minutes was determined in Heidenhain and also in total pouch dogs. The relationship between dose of histamine and magnitude of inhibition by a fixed dose of depressant as well as the relationship between magnitude of response to a fixed dose of histamine and magnitude of inhibition by a fixed dose of depressant were studied. The relationship between dose of secretory depressant and magnitude of inhibition was also studied.

Effects of homologous carbamates on the respiration of blocked and active embryonic cells JOSEPH HALL BODINE and LAURENCE ROCKWELL FITZGERALD (by invitation), *Zoology Lab., State Univ. of Iowa, Iowa City, Ia.* A study was made of the effects of an homologous series of carbamates (ethyl n-methyl, ethyl, n-butyl, n-propyl, n-amyl, iso-amyl) on the oxygen uptake of mitotically active and blocked embryos of the grasshopper, *Melanoplus differentialis*. No significant differences in response to these reagents have been found for active and blocked embryonic cells. In general, all reagents produce a marked inhibition in the oxygen uptake. Ethyl carbamate in low concentrations seems to produce a marked and consistent stimulation while all other compounds tested by the present methods did not produce such results. A discussion of the present results, in view of the many existing theories of narcosis, is given.

Influence of hesperidin methyl chalcone on blood flow and secretion of the salivary gland DAVID F. BOHR and W. JOHN KENFIELD (introduced by Robert Gesell), *Dept. of Physiology, Univ. of Michigan, Ann Arbor, Mich.* This study of the influence of hesperidin methyl chalcone (HMC) on the rate of salivary secretion and of blood flow through the submaxillary gland of the dog has been directed towards an understanding of the cause of vascular changes produced by this drug. One mg. HMC/kg. body weight injected into the internal carotid artery did not alter the rate of blood flow or of salivary secretion of the gland. The same amount of HMC injected into the external carotid artery supplying the gland caused a striking increase in blood flow through the gland but did not alter rate of salivary secretion. These local injections had no influence on the secretory or blood flow changes produced by stimulation of the chorda tympani or the sympathetic trunk innervating the gland. Similarly the vasoconstrictor and secretory actions of epinephrine were still evident after the administration of HMC. Autonomic blockade with tetraethyl ammonium chloride did not change the vasodilator action of HMC. It would appear then,

that this vasodilatation is the result of the local action of HMC on the vascular musculature. Neither a central nervous system action nor a peripheral one on the autonomic nerves supplying the submaxillary gland was demonstrated.

Effect of choline and inositol on hypercholesterolemia and hyperlipemia in the cholesterol-fed chick C BOLENE (by invitation), J STAMLER (by invitation), R HARRIS (by invitation) AND L N KATZ *Cardiovascular Dept., Medical Research Institute, Michael Reese Hospital, Chicago, Ill.* In experiments designed to determine the biochemical parameters of the atherosclerogenic process, we have undertaken studies on factors affecting the plasma content of cholesterol, phospholipids and fatty acids. Addition of 2% cholesterol to the normal diet of the chick results in a hyperlipemia involving all lipid elements. The degree of development of atherosclerosis is in general related to the degree of increase in these constituents in the plasma. Addition of lipotropic factors to such cholesterol-rich diets in the form of 1% choline plus 1% inositol resulted in a more marked hypercholesterolemia and hyperphospholipemia. This effect is progressive with values at 1, 3, 5 and 8 weeks increased to levels about 50% above the non-lipotrope-fed birds. This occurred despite the fact that there were no significant differences in food intake and weight gain. These results suggest that these lipotropes act to mobilize liver lipids and produce a prolonged transport hyperlipemia. Choline and inositol failed to modify or prevent atherosclerosis in birds killed after 15 weeks or diet.

Experimental studies in ascorbic acid metabolism WALTER M BOOKER, RAYMOND HAYES (by invitation) and MARIANNA SEWELL (by invitation) *Depts. of Pharmacology and Oral Medicine, Howard Univ., Washington, D. C.* Clinical studies underway in this laboratory on ascorbic acid metabolism and its relation to certain gingival disturbances have provoked many new experimental approaches to the problem of ascorbic acid metabolism and the effects of ascorbic acid on the metabolism of other substances in the animal body. In unanesthetized and anesthetized dogs ascorbic acid administered at the rate of 100 mg. hourly for 3 hours rises rapidly in the plasma and slowly in the cells. Only after the second hour is a significant increase noted in the cells. This suggests a barrier between the plasma and the cells. There is some evidence that the adreno-cortical hormone can lower the barrier, causing a more rapid rise in the cells. In both unanesthetized and anesthetized dogs, ascorbic acid administered either hourly or by constant drip causes interesting changes in the electrolytes of the blood, such as a fall in chlorides, in sodium and a rise in potassium. Urinary chlorides and sodium rise, while potassium falls. Adreno-cortical extract, administered at intervals while ascorbic acid

is being given, causes a decrease in the urinary sodium and chlorides, while these substances may rise in blood toward the control or beginning levels. In some instances, under the influence of the adreno-cortical hormone, the urinary chlorides decrease without significant increase in serum chlorides. Thiocyanate space and blood volume studies suggest movement of chlorides to extracellular spaces. Evidence has been obtained showing ascorbic acid in high quantities causes a diminution of blood cholesterol and of cholesterol at the adrenal gland, where greater the amount of ascorbic acid, the less the cholesterol. Adreno-cortical hormone can increase adrenal storage of ascorbic acid.

Localization of the central nervous mechanism of emesis H L BORISON (by invitation) and S C WANG *Dept. of Physiology, College of Physicians and Surgeons, Columbia Univ., New York City.* By means of electrical stimulation with the Horsley-Clarke stereotaxic instrument, the vomiting center has been functionally localized in the dorso-lateral portion of the lateral reticular formation of the medulla oblongata of the cat (Borison and Wang, to be published). This finding is of particular significance since it has been shown that responsive loci for salivation (Wang, 1943), spasmodic respiratory movement (Borison, 1948), vasomotor effects (Wang and Ranson, 1939), and sustained inspiration (Pitts et al, 1939) are situated in areas immediately adjacent to that localized for emesis. Several dogs have been prepared with chronic lesions in the medulla for the purpose of dissociating the component activities involved in emesis. Preliminary experiments indicate that with lesions up to 30-day duration the emetic response to apomorphine is either seriously impaired or completely eliminated. Histological study has not yet been carried out on any of the tested preparations but gross examination of the brains of animals which did not survive the procedure indicate that the lesions are placed approximately in the dorso-lateral portion of the lateral reticular formation. Attempts will be made to correlate the degree of impairment of emesis with the size and position of the lesions.

Renal function in untreated adrenalectomized rats W R BOSS (by invitation), JAMES H BIRNIE (by invitation) and ROBERT GAUNT *Dept. of Zoology, Syracuse Univ., Syracuse, N. Y.* Studies of renal function in salt-maintained adrenalectomized rats indicate that renal clearance is essentially normal (Lotspeich, Friedman *et al.*). Water excretion tests, however, indicate serious alterations in renal function. Creatinine clearance studies were conducted on untreated fasted female normal and adrenalectomized rats weighing approximately 175 gm., following methods used by Lotspeich. Ninety-six rats, divided equally between the various groups studied, were used in this investigation. The glomerular filtration rate (CC_r) of normal rats given

oxygen difference 11 vol %, and the O_2 consumption 7.8 cc/100 gm/min. In anemia the coronary flow was increased, the arteriovenous O_2 difference and the O_2 consumption were reduced. In essential hypertension the coronary flow was normal, the arteriovenous O_2 difference and the O_2 consumption were decreased. In coarctation the coronary flow, the arteriovenous O_2 difference, and the O_2 consumption were markedly increased. In cardiac failure the coronary flow was reduced but the arteriovenous O_2 difference was increased. The O_2 consumption was slightly above normal. As a result of these changes the cardiac efficiency was highest in essential hypertension and lowest in cardiac failure. The lowered cardiac efficiency in failure was primarily the result of decreased left ventricular work. Correlation between the work and the O_2 consumption of the left ventricle was good except in essential hypertension and cardiac failure.

Properties of the antidiuretic substance in the blood of normal and adrenalectomized rats. J. H. BIRNIE (by invitation), W. J. EVERSOLE (by invitation), W. R. BOSS (by invitation), C. M. OSBORN (by invitation) and ROBERT GAUNT, *Dept. of Zoology, Syracuse Univ., Syracuse, N. Y.* It has been reported (Birnie, Jenkins, Eversole and Gaunt—in press) that the blood of normal rats contains an antidiuretic, chloruretic substance (ADS). It was readily detectable by a modified Heller and Urban assay procedure in 1 ml. quantities of fresh serum injected intraperitoneally. The serum lost its activity upon standing at 9°C. for 12 hours, and was present in greater quantities in adrenalectomized than in normal rats. The latter observation will presumably help explain the well-known failure of water diuresis in adrenalectomized animals. Newer experiments have shown the following: 1) ADS was not detected in 1 ml. samples of the serum of rats hypophysectomized from 4 to 11 days. 2) The ADS of normal rat serum (1 ml.) does not affect renal glomerular filtration as indicated by creatinine clearance tests and presumably therefore works by stimulating the tubular reabsorption of water. 3) The ADS is active when injected subcutaneously but less effective than by intraperitoneal administration. 4) Unlike the ADS, an isotonic gelatin solution, prepared for blood substitute use, has no effect on diuresis in 1 ml. doses. 5) Crude protein solutions, injected intraperitoneally, may inhibit diuresis by other mechanisms; they differ from ADS in that they act less promptly and are not chloruretic. All of these observations are consistent with the idea that the circulating ADS is the antidiuretic hormone of the posterior pituitary.

Analysis of factors affecting the assay of gastric secretory depressants. D. BLICKENSTAFF (by invitation) and M. I. GROSSMAN, *Dept. of Clinical Science, Univ. of Illinois College of Medicine, Chicago, Ill.* In order to design an efficient and accurate

assay procedure, the factors which contribute to the variability of results in assaying gastric secretory depressants were studied statistically. The relationship between dose of histamine and magnitude of inhibition by a fixed dose of depressant as well as the relationship between magnitude of response to a fixed dose of histamine and magnitude of inhibition by a fixed dose of depressant were studied. The relationship between dose of secretory depressant and magnitude of inhibition was also studied.

Effects of homologous carbamates on the respiration of blocked and active embryonic cells. JOSEPH HALL BODINE and LAURENCE ROCKWELL FITZGERALD (by invitation), *Zoology Lab., State Univ. of Iowa, Iowa City, Ia.* A study was made of the effects of an homologous series of carbamates (ethyl n-methyl, ethyl, n-butyl, n-propyl, n-amyl, iso-amyl) on the oxygen uptake of mitotically active and blocked embryos of the grasshopper, *Melanoplus differentialis*. No significant differences in response to these reagents have been found for active and blocked embryonic cells. In general, all reagents produce a marked inhibition in the oxygen uptake. Ethyl carbamate in low concentrations seems to produce a marked and consistent stimulation while all other compounds tested by the present methods did not produce such results. A discussion of the present results, in view of the many existing theories of narcosis, is given.

Influence of hesperidin methyl chalcone on blood flow and secretion of the salivary gland. DAVID F. BOHR and W. JOHN KENFIELD (introduced by Robert Gesell), *Dept. of Physiology, Univ. of Michigan, Ann Arbor, Mich.* This study of the influence of hesperidin methyl chalcone (HMC) on the rate of salivary secretion and of blood flow through the submaxillary gland of the dog has been directed towards an understanding of the cause of vascular changes produced by this drug. One mg. HMC/kg. body weight injected into the internal carotid artery did not alter the rate of blood flow or of salivary secretion of the gland. The same amount of HMC injected into the external carotid artery supplying the gland caused a striking increase in blood flow through the gland but did not alter rate of salivary secretion. These local injections had no influence on the secretory or blood flow changes produced by stimulation of the chorda tympani or the sympathetic trunk innervating the gland. Similarly the vasoconstrictor and secretory actions of epinephrine were still evident after the administration of HMC. Autonomic blockade with tetraethyl ammonium chloride did not change the vasodilator action of HMC. It would appear then,

that this vasodilatation is the result of the local action of HMC on the vascular musculature. Neither a central nervous system action nor a peripheral one on the autonomic nerves supplying the submaxillary gland was demonstrated.

Effect of choline and inositol on hypercholesterolemia and hyperlipemia in the cholesterol-fed chick. C. BOLENE (by invitation), J. STAMLER (by invitation), R. HARRIS (by invitation) and L. N. KATZ, *Cardiovascular Dept., Medical Research Institute, Michael Reese Hospital, Chicago, Ill.* In experiments designed to determine the biochemical parameters of the atherosclerogenic process, we have undertaken studies on factors affecting the plasma content of cholesterol, phospholipids and fatty acids. Addition of 2% cholesterol to the normal diet of the chick results in a hyperlipemia involving all lipid elements. The degree of development of atherosclerosis is in general related to the degree of increase in these constituents in the plasma. Addition of lipotropic factors to such cholesterol-rich diets in the form of 1% choline plus 1% inositol resulted in a more marked hypercholesterolemia and hyperphospholipemia. This effect is progressive with values at 1, 3, 5 and 8 weeks increased to levels about 50% above the non-lipotope-fed birds. This occurred despite the fact that there were no significant differences in food intake and weight gain. These results suggest that these lipotropes act to mobilize liver lipids and produce a prolonged transport hyperlipemia. Choline and inositol failed to modify or prevent atherosclerosis in birds killed after 15 weeks on diet.

Experimental studies in ascorbic acid metabolism. WALTER M. BOOKER, RAYMOND HAYES (by invitation) and MARIANNA SEWELL (by invitation), *Depts. of Pharmacology and Oral Medicine, Howard Univ., Washington, D. C.* Clinical studies underway in this laboratory on ascorbic acid metabolism and its relation to certain gingival disturbances have provoked many new experimental approaches to the problem of ascorbic acid metabolism and the effects of ascorbic acid on the metabolism of other substances in the animal body. In unanesthetized and anesthetized dogs ascorbic acid administered at the rate of 100 mg. hourly for 3 hours rises rapidly in the plasma and slowly in the cells. Only after the second hour is a significant increase noted in the cells. This suggests a barrier between the plasma and the cells. There is some evidence that the adreno-cortical hormone can lower the barrier, causing a more rapid rise in the cells. In both unanesthetized and anesthetized dogs, ascorbic acid administered either hourly or by constant drip causes interesting changes in the electrolytes of the blood, such as a fall in chlorides, in sodium and a rise in potassium. Urinary chlorides and sodium rise, while potassium falls. Adreno-cortical extract, administered at intervals while ascorbic acid

is being given, causes a decrease in the urinary sodium and chlorides, while these substances may rise in blood toward the control or beginning levels. In some instances, under the influence of the adreno-cortical hormone, the urinary chlorides decrease without significant increase in serum chlorides. Thiocyanate space and blood volume studies suggest movement of chlorides to extracellular spaces. Evidence has been obtained showing ascorbic acid in high quantities causes a diminution of blood cholesterol and of cholesterol at the adrenal gland, where greater the amount of ascorbic acid, the less the cholesterol. Adreno-cortical hormone can increase adrenal storage of ascorbic acid.

Localization of the central nervous mechanism of emesis. H. L. BORISON (by invitation) and S. C. WANG, *Dept. of Physiology, College of Physicians and Surgeons, Columbia Univ., New York City.* By means of electrical stimulation with the Horsley-Clarke stereotaxic instrument, the vomiting center has been functionally localized in the dorso-lateral portion of the lateral reticular formation of the medulla oblongata of the cat (Borison and Wang, to be published). This finding is of particular significance since it has been shown that responsive loci for salivation (Wang, 1943), spasmodic respiratory movement (Borison, 1948), vasomotor effects (Wang and Ranson, 1939), and sustained inspiration (Pitts et al., 1939) are situated in areas immediately adjacent to that localized for emesis. Several dogs have been prepared with chronic lesions in the medulla for the purpose of dissociating the component activities involved in emesis. Preliminary experiments indicate that with lesions up to 30-day duration the emetic response to apomorphine is either seriously impaired or completely eliminated. Histological study has not yet been carried out on any of the tested preparations but gross examination of the brains of animals which did not survive the procedure indicate that the lesions are placed approximately in the dorso-lateral portion of the lateral reticular formation. Attempts will be made to correlate the degree of impairment of emesis with the size and position of the lesions.

Renal function in untreated adrenalectomized rats. W. R. BOSS (by invitation), JAMES H. BIRNIE (by invitation) and ROBERT GAUNT, *Dept. of Zoology, Syracuse Univ., Syracuse, N. Y.* Studies of renal function in salt-maintained adrenalectomized rats indicate that renal clearance is essentially normal (Lotspeich, Friedman et al.). Water excretion tests, however, indicate serious alterations in renal function. Creatinine clearance studies were conducted on untreated fasted female normal and adrenalectomized rats weighing approximately 175 gm., following methods used by Lotspeich. Ninety-six rats, divided equally between the various groups studied, were used in this investigation. The glomerular filtration rate (CC_r) of normal rats given

5 \bar{V} cc of water by stomach tube was 820 cc/100 gm/min and the urine flow (V) was 022 cc/min. Eighteen hours after adrenalectomy the C_{Cr} was 686 and the V was 015. Five days after operation the C_{Cr} was 551 while the V was 013. When adrenalectomized rats were subjected to moderate and high water loads, the disproportionate fall in glomerular filtration rate and urine excretion rate was even more striking. When two hourly doses of water were administered (3% body surface/dose) the C_{Cr} of the dummy operated controls was 1 011 and the V 083, in rats adrenalectomized for 18 hours the C_{Cr} had fallen to 759 and the V to 041, 7 days after adrenalectomy the C_{Cr} was decreased to 701 with a V of 008. When 4 hourly doses of water were administered the C_{Cr} of the dummy operated controls was 1 010 and the V 118, 18 hours after adrenalectomy the C_{Cr} had fallen to 590 and the V to 031, 7 days after operation the C_{Cr} was down to 447 with a V of only 006. These results show that the rate of urine flow falls in all cases more than the rate of glomerular filtration. This indicates that in untreated, in contrast to salt-treated adrenalectomized rats, a decreased glomerular filtration may contribute to loss of water diuresis, but that an increase in tubular reabsorption of water is probably a more important factor.

A method for analyzing dog muscles for myoglobin WILLIAM J BOWEN *Laby of Physical Biology, Exptl Biology and Medicine Institute, National Institutes of Health, Bethesda, Md*. A method has been devised for analyzing dog muscle for myoglobin (Mb) in the presence of hemoglobin. Cleaned muscle is pulverized at the temperature of dry ice as described by Poel (*Science* 108 390, 1948). An exactly known quantity (about 1 gm) of the muscle powder is washed into a stainless steel homogenizer tube with a carefully measured volume (about 20 ml) of M/40 phosphate buffer, pH 5.9. It is thoroughly homogenized and then centrifuged at 1000 g for 10 minutes. The supernatant is heated to 56°. As soon as discrete particles appear, the extract is rapidly cooled and then centrifuged at 1000 g for 10 minutes. It is filtered through fast paper from which it emerges as a clear red solution. This is adjusted to pH 6.5 with solid K_2HPO_4 and then gassed with CO in a rotating tonometer. To insure complete conversion to MbCO, $Na_2S_2O_4$ is added to the tonometer after 10 minutes of gassing. After a total of 12 minutes of gassing the density (log I_0/I) of the solution is determined at 538 and 568 m μ . The molar concentration of Mb is calculated by substitution of the densities and the appropriate extinction coefficients for MbCO and HbCO in the Vierordt equation (*Ann Rev Biochem* 10 509, 1941). The amount of myoglobin/gm of muscle is calculated by using the molecular weight 17,300 (Bowen, *J Biol Chem* 176 747, 1948). By this method 9 samples of one heart, having an average of

3.60 mg Mb/gm of muscle, yielded a $\sigma = 0.28$ and a coefficient of variation = 8%. Also, a known quantity of dog myoglobin added to muscle homogenate was recovered 100%.

Hypoxia of 18,000 feet simulated altitude and myoglobin content of dogs WILLIAM J BOWEN *Laby of Physical Biology, Exptl Biology and Medicine Institute, National Institutes of Health, Bethesda, Md*. The left anterior trapezius muscle of 7 dogs was removed by biopsy and analyzed for myoglobin content by the method described in preceding abstract. The dogs were then exposed to 18,000 ft simulated altitude 6 hours per day, 6 days per week. Hematocrit and hemoglobin values and changes in body weight were followed as criteria of acclimatization. After 5 to 6 months of exposure the dogs were sacrificed and the trapezius muscle from the other side analyzed for myoglobin content. Final hematocrit and hemoglobin values were 119 to 170 and 122 to 170%, resp., of initial values. Body weights in each dog increased during the first month of exposure and then remained nearly constant. The myoglobin contents before and after exposure were as follows:

Dog	Mg Mb/gram of wet muscle	
	Before Exposure	After Exposure
1	3.27*	2.80
2	4.70*	4.33
3	5.20*	4.73
4	4.60	4.20
5	4.42*	4.62
6	5.07	3.75
7	3.80	4.22

These values are means obtained in repeated or duplicate analyses, except those marked (*). One value deviated 11% from the mean, another 8%. The remainder deviated 5% or less. The results indicate that exposure to simulated altitude of 18,000 ft causes no increase in the Mb content of muscle in contrast to the response of the hemoglobin of blood.

Principles of design and operation of internal standard flame photometers for sodium and potassium determination ROBERT L BOWMAN and ROBERT W BERLINER (introduced by DAVID P EARLE, JR.) *New York Univ Research Service, Goldwater Memorial Hospital, New York City*. Construction of two internal standard flame photometers for sodium and potassium has led to improvements in design and technique of operation. The basic aims have been simplicity of design and establishment of operating conditions in which minor variations of gas and air pressures, atomizing rates, etc. are maximally compensated by parallel changes in the output of cells measuring light from unknown and internal standard. Critical mechanical and electrical components were evaluated for their contribution to stability and accuracy, and extensive study made of parameters determining stability and independence of external variables.

Optimum operating conditions must be evaluated individually for each instrument by determining, separately, for sodium, potassium and lithium, a number of curves relating electrical output to atomizing rate, gas and air pressure, and ion concentration. Operating conditions are selected so that, as nearly as possible, changes in any of these will produce no effect on reading or be maximally compensated by the internal standard. Changes in gas and air pressures which may effect readings are corrected by resetting, emphasis being upon indication with sensitive gauges rather than automatic pressure regulation. Application of these principles to other instruments has been reported to be of material aid. With the present instruments over 6000 and 9000 determinations, in 14 months and 2 years respectively, have been made without interruption for repairs. Accuracy attainable with single readings of unknowns is ± 1.0 and $2.0 \mu\text{eq/l}$ for potassium and sodium respectively in the diluted sample. No interference from other substances in solution is detectable.

A new method of fibrin determination and applications to study of the thrombin-fibrinogen reaction PAUL W. BOYLES (by invitation) and JOHN H. FERGUSON *Dept of Physiology, Univ of North Carolina, Chapel Hill*. Determination of fibrin by the biuret method (J. Fine, *J Lab Clin Med* 24: 1084, 1936) was modified by use of Mehl's (*J Biol Chem* 157: 173, 1945) reagent, photoelectric colorimetry, and calibration of colorimetric readings against both gravimetric (fibrin dry weight) and macroKjeldahl (fibrin N) determinations. A commercial (Armour's) bovine plasma fraction-I, analyzing 50% fibrinogen (clottable), after reprecipitation at 2-5°C with ammonium sulfate at 25, 20, 20% saturation, successively, with subsequent dialysis, yielded fibrinogen solutions 96.7% clottable, with only minute traces of prothrombin, and no fibrinolytic protease. Clotting-times and fibrin yields were studied with variations of 1) fibrinogen concentration, 2) thrombin concentration (purified bovine thrombin), 3) temperature, 4) pH, 5) NaCl content, 6) Ca ion content, 7) added colloid (acacia), 8) heat (48°, 12 min) induced profibrin, 9) time after clotting (at 37°C). After 48 hr the fibrin yields were practically identical (aver over 95%) independent of the above variables, except for inhibitory concentrations of NaCl and CaCl_2 , which reduced yields significantly (e.g. 65% in 0.5 M CaCl_2). Clotting-times were much modified by these variables. It is particularly significant that the 48-hr fibrin yield was unaltered by varying the thrombin dilution from 1:1 to 1:250, despite a range of clotting-times, for the series, of 10 to 190 seconds. It is concluded that the thrombin-fibrinogen reaction does not follow any simple stoichiometric law but resembles the reaction kinetics of a colloidal enzymatic reaction.

Adsorption of urinary gonadotrophin on kaolin

JAMES T. BRADBURY, ELWIN BROWN and WILLIS E. BROWN *Dept of Gynecology, Univ of Louisville, Louisville, Ky, and State Univ of Iowa, Iowa City, Ia*. The following method has been devised for recovery of gonadotrophic hormones. Its main advantages are 1) reduction in toxicity of the extracts and 2) a marked saving the amount of alcohol needed.

The urine of a 12- or 24-hour specimen is adjusted to pH 4.5 with acetic acid. Add 5 volumes % of kaolin (powdered and acid washed in a 20% aqueous suspension), stir thoroughly and then allow to settle. Decant supernatant urine. Centrifuge and discard supernatant. (Kaolin may be re-suspended in water one to three times to wash it free of urine.) Add normal ammonium hydroxide in a volume equal to that of the original kaolin suspension used and stir thoroughly. Centrifuge and re-extract with a second volume of ammonium hydroxide. Combine the ammonia extracts, add acetic acid to pH 8.5 and centrifuge. Save the clear supernatant, adjust to pH 5.5 and add 4 volumes of 95% alcohol slowly while stirring. Set in refrigerator several hours to complete the precipitation. Centrifuge and dry the precipitate.

The dry precipitate is dissolved in water or phosphate buffer pH 8.0 and the solution injected into immature rats or mice for assay. The recoveries of gonadotrophins from pregnancy or castrate (post-menopausal) urines have been quantitative when compared with those obtained by the usual method of adding 4 volumes of alcohol to the original urine specimen.

Analysis of mosquito tissues for sodium and potassium and development of a physiological salt solution SARAH BRADFORD (by invitation) and ROBERT W. RAMSEY *Dept of Physiology and Pharmacology, Medical College of Virginia, Richmond, Va*. The midgut and Malpighian tubules of *Aedes aegypti* were analyzed for their content of sodium and potassium. The tissues from 1000 mosquitoes were pooled to provide sufficient Na and K for one analysis. A total of 6 such analyses were done. The Na and K content of the midguts and Malpighian tubules of 1000 mosquitoes kept on a normal diet averaged 6.91 mg Na/gm dry weight of tissue and 15.6 mg of K/gm dry weight. Both the sodium and potassium contents decrease with time on a salt free diet until after two weeks sodium is reduced to 2.5 mg/gm dry weight and potassium to 10.4 mg/gm dry weight. Malpighian tubules have a lower potassium content than midgut. No differences in sodium or potassium content due to age or sex of the mosquitoes were noted.

A physiological salt solution having the following composition was developed for mosquito tissues: NaCl-128 mM/l, KCl-4.7 mM/l, CaCl_2 -4.0 mM/l, M/150 potassium phosphate buffers to pH 6.8. Ex-

cept for the added buffer (which contributes 11.34 mM/l of K) this solution is the same as that which Bodenstein previously found best for *Drosophila*. This solution will maintain in the cold, a mosquito heart preparation alive and beating for as long as 280 hr. If small amounts of the B vitamins or p-aminobenzoic acid are added to the above the average survival is prolonged but the maximum so far found (300 hr) is about the same. Mosquito hearts can survive for as long as 30 hr in salt solutions that are very high in potassium and low in sodium provided sufficient magnesium is present.

Light tonus of the human eye G. A. BRECHER (introduced by C. J. WIGGERS) *Dept. of Physiology, Univ. of Prague, Czechoslovakia, and Dept. of Physiology, Western Reserve Univ. Medical School, Cleveland, Ohio*. The tonus of the eye muscles and thus the muscular balance of the nonfixating eye is maintained by various reflexes, among which light tonus plays an important rôle in lower animals. No such light tonus has been proven for the human eye. The influence of light upon the heterophoria of the nonfixating eye was measured in 21 normal subjects with a new method permitting the continuous recording of heterophorias under varying optical conditions. The nonfixating eye displays a greater heterophoria upon diffuse illumination than in the dark. The increase of the eye deviation is greatest immediately after the light exposure, and reaches its maximum in about 2 minutes, after which time no appreciable increase can be recorded. The heterophoria increase/time ratio follows the course of a parabola. Upon discontinuation of the illumination the heterophoria decreases to the same value which it previously had in the dark. The degree of the heterophoria is directly proportional to the light intensity. Illumination of the fixating eye causes also a heterophoria increase of the nonfixating eye, indicating the consensual nature of the mechanism involved. It is assumed that the heterophoria increase upon illumination of the retina is due to the existence of a light tonus which contributes to maintain the muscular balance of the nonfixating eye.

Chronic toxicity studies on hydroquinone N. R. BREWER (by invitation) and A. J. CARLSON *Physiology Lab., The Univ. of Chicago, Chicago, Ill.* Hydroquinone added to food fats in the amount of 0.01% decreases the rate of oxidative rancidity from 2 to 50 times, thus reducing food deterioration and food spoilage. Is this amount injurious to the health of man or animals? The following tests have been run to answer this important question. 1) Twenty weanling rats, started on a diet containing 0.25% hydroquinone, showed no evidence of toxic effects (growth, reproduction, autopsy findings) after 2 years on test when compared to 20 controls. Twenty offspring of these rats were continued on this test for a year with no signs of toxic effects.

Twenty rats were fed a diet containing 1.0% hydroquinone. After 2 years the only finding was a slight decrease in the rate of growth as measured by body weight. Fourteen rats were fed a diet containing 5.0% hydroquinone. The rats consumed very little food, lost weight rapidly, and after 9 weeks some of them developed a blood condition resembling aplastic anemia. 2) Dogs refused to eat food (apparently because of the bitter taste) containing more than 0.02% hydroquinone in the total diet. By placing the hydroquinone in sugar coated tablets in the food, one dog consumed 16 mg hydroquinone/kg/day for 34 weeks, without any evidence of injury when compared with 3 control sibs. Sixteen mg/kg/day is a 160-day supply/day, or a 100-year supply for 34 weeks, for man, if man were to ingest 1 gm fat/kg/day and all of the fat were treated with 0.01% hydroquinone. 3) Cats appear more susceptible to hydroquinone. But 10 mg hydroquinone/kg/day for 6 weeks showed no untoward symptoms to date, when given to 1 of 4 young sibs, and 15 mg/kg/day for 6 weeks showed only a small decrease in the growth acceleration curve when given to another sib. Fifteen mg/kg/day is a 150-day supply per day, a 17-year supply for 6 weeks, for man, if man were to ingest 1 gm of fat/kg/day and all of the fat were treated with 0.01% hydroquinone.

Factors influencing contractile force of the heart in open-chest mammalian experiments H. H. BRILL, M. DE V. CORRON and R. P. WALTON (introduced by T. G. Bernthal), *Dept. of Pharmacology, Medical College of South Carolina, Charleston, South Carolina*. Contractile force of a section of the right ventricle was measured directly by means of variable spring tensions inserted in the system of levers of the Cushny myocardiograph typically attached in open-chest preparations. All experiments were carried out on vagotomized dogs, with pericardium opened and with high oxygen concentrations in the mechanical respiratory system. Compensation for changes in heart size were accomplished in two ways: 1) by preliminary calibrations which determined the effect of measured changes in position of the collar which mechanically protected the muscle section from being stretched beyond the usual point of diastolic relaxation; 2) by adjustment of this collar as heart size changed. (This latter has been facilitated by construction of a micrometer screw adjustment mechanism.) Moving and re-setting this collar over wide ranges demonstrated that the muscle section could be stretched to approximately twice its diastolic resting length with an increase in contractile force several hundred percent greater than that of the control period. Within this range, progressive increments of stretch produced progressive increments of contractile force in a linear relationship. Progressive increments of venous

pressure obtained by massive saline infusions and progressive decrements of venous pressure obtained by venous hemorrhage resulted in moderate changes in contractile force which, in a few experiments, followed the linear relationships of Starling's Law but for the most part appeared to be substantially affected by other factors. Partial occlusion of the inferior vena cava lowered venous pressure, contractile force and arterial pressure, the effects apparently operating in close association. Partial occlusion of the pulmonary artery and of the aorta produced, in each case, only limited effects. Sudden release of constriction in the vena cava, the pulmonary artery or the aorta frequently produced an immediate transient increase in contractile force and stroke amplitude distinctly greater than that of the control period. Substantial decreases in contractile force (30-60%) were obtained by ligation of coronary arteries supplying the area of lever attachments.

Gravity and applied accelerations S W BRITTON and O B MURRAY, JR (by invitation) *Physiological Lab, Univ of Virginia, Charlottesville, Va*. The effects of gravitational force on the circulation have been observed to be similar to those exerted by a force of 1 *g* imposed on an animal on a centrifuge with 10-ft rotor arm. ECG, arterial blood pressure, heart rate and other determinations were made over periods up to one hour with forces directed from head to foot and *v v*, or positive and negative *g*.

Compared to the influence of 1 *g* applied by centrifuge or tilt-table continuously for 30 minutes, dogs showed similar resistance to 3-4 *g* applied discontinuously or alternately, 5 seconds on and 5 seconds off, over the same period. On the basis of *g*-minutes employed, it is noteworthy that the organism withstands about twice as much stress (in force-time) in the latter as in the former case, or 45-60 *g*-minutes compared to 30 *g*-minutes.

Discontinuous forces even as high as 6 *g*, 5 seconds on and off, were well withstood for periods of 30 minutes. Quadrupeds are nevertheless much less resistant to gravitational and high acceleratory forces than primate animals and man.

Effect of hypothermia on bromsulphalein removal RADFORD BROKAW (introduced by K E PENROD) *Dept of Physiology, Boston Univ School of Medicine, Boston, Mass*. In normothermic dogs under moderate sodium pentothal anesthesia the percentage disappearance rate of intravenously injected bromsulphalein is not constant, but is nevertheless prompt and rapid. Sixteen anesthetized dogs were injected at normal body temperature with bromsulphalein (5 mg/kg). Blood samples at 6 minutes showed an average level of 1.85 ± 0.93 mg/100 cc of plasma, and 12 minute samples averaged 0.65 ± 0.20 mg/100 cc or 35% of the 6-minute level. Following this marked initial fall

there was a more gradual decline in the concentration of bromsulphalein so that by 30 minutes 0.314 ± 0.11 mg/100 cc remained, or 17% of the 6-minute blood level. When 7 anesthetized dogs were immersed in an ice bath and the injection given intra-arterially at 35° C rectal temperature, the average plasma level after 6 minutes was 4.53 ± 1.44 mg/100 cc. In 12 minutes the average plasma level was 2.89 ± 1.62 mg/100 cc or 64% of the 6-minute level. Ten dogs received the dye injection at 30° C rectal temperature. Their 6-minute levels averaged 4.82 ± 1.25 mg/100 cc, with the 12-minute samples showing 3.24 ± 0.93 mg/100 cc, an average of 67% remaining. Both series of hypothermic dogs showed a marked retention of the dye after 30 minutes. In the 35° C group an average of 1.68 ± 1.03 mg/100 cc was obtained. These values represent 37% and 43% of the dye remaining respectively from the 6-minute plasma levels as contrasted with only 17% remaining in the normothermic controls. These data indicate that hypothermia decreases both the quantitative and relative amounts of bromsulphalein removed.

Temporal relations in the auditory pathway JOHN M BROOKHART and HARLOW W ADES *Dept of Physiology, Northwestern Univ Medical School, Chicago, Ill, and the Dept of Anatomy, Emory Univ School of Medicine, Emory University, Ga*. Unipolar recordings of responses from various stations along the auditory pathway have been recorded using anesthetized cats. Monaural and binaural click stimuli were furnished by brief condenser discharges activating hearing-aid receivers.

Introductory deflections, preceding the principal responses from the cortex, radiation and geniculate, occur at the same time as discharges from the inferior colliculus and are possibly due to electrotonic conduction from mid brain levels.

Latencies of responses to monaural stimulation from a single animal typical of the series are given below in msec.

	AUD CORT	AUD RAD	MED GENIC	BR INF COLL	INF COLL	TRAP BODY	AU TU BER
Ipsi	7.5-8.0	6.0-7.0	5.5-6.0	3.5	3.5	2.0	1.0
Contra	7.5-8.0	6.0-7.0	5.5-6.0	2.5	2.5	2.0	1.5

The lapse of 2.0 msec between the geniculate and cortical responses, and of 2.5-3.5 msec between the brachial and geniculate responses suggests either multiplicity of synapses or unusually long nuclear delays at these points. The geniculate response is similar in crest time and duration to the cortical response and seems to be unaffected by removal of the ipsilateral cortex. The differences in the latencies of ipsilateral and contralateral responses at mid brain levels suggest that one more synapse

is involved in the ipsilateral pathway. The significance of the findings with respect to the functional anatomy of the auditory system are discussed.

Analysis of the mechanism of diurnal rhythmicity in crustacea FRANK A. BROWN, JR. and H. MARGUERITE WEBB (by invitation) *Dept. of Zoology, Northwestern Univ., Evanston, Ill.* and *Marine Biological Lab., Woods Hole, Mass.* A well-defined daily rhythmicity of color change occurs in the fiddler crab, *Uca pugnax*. The rhythm persists for many weeks completely in phase with the day-night cycle in conditions of constant darkness, temperature, and humidity. A study was made of the influence of constant illumination, and changes from constant illumination to constant darkness at different times of the day-night cycle, and of alternating periods of light and darkness, different from those of the normal day-night illumination changes. An analysis of the results indicated that the phases of the diurnal rhythm could be altered abruptly by some types of light stimulation administered at certain 'sensitive' periods in the daily cycle, but could not be altered by similar stimuli at other periods. The results appeared, furthermore, to indicate clearly that two centers of rhythmicity were present, each one capable of having its rhythm altered independently of the other, but with one more basic center of inherent rhythmicity capable of influencing gradually a second center having less persistent rhythmicity.

Absorption and excretion of carbon¹⁴ as CO₂ and bicarbonate AUSTIN M. BRUES and AGNES NARANJO (by invitation) *Argonne National Lab., Chicago, Ill.* As shown previously, the mouse exposed to C¹⁴O₂ in a closed system rapidly attains a steady state in which the C¹⁴ in the animal approximates the amount originally in a volume of air ten times the volume of the mouse. This labile carbon compartment appears to be somewhat greater than the inorganic body carbon, excluding bone carbonate. Excretion rates after a 30-minute confinement period show a small portion of the body C¹⁴ to be in somewhat more stable combination.

Because of the great rapidity of absorption of C¹⁴O₂, we have measured the clearance of the tracer gas from air breathed through a tracheal cannula by rats under Nembutal anesthesia. Initially, the expired air contains less than one-half the C¹⁴O₂ concentration of the inspired air, although the CO₂ concentration is naturally much higher.

To make conditions as favorable as possible for fixation of C¹⁴, mice were injected with labelled sodium bicarbonate and allowed to rebreathe expired air for 10 hr. in a 20-liter chamber. Various tissues were analyzed at intervals up to 2 months after removal. It is estimated that less than 2% of the body carbon had exchanged with blood bicarbonate at the end of exposure. Of this retained

carbon, about 90% was lost within a week, beyond this time the rate of loss was relatively slow.

Newborn mice receiving C¹⁴ by exposure of their mothers prior to delivery lose C¹⁴ much more slowly than adult mice, but the specific activity of their body carbon decreases rapidly due to growth.

Further studies on the pepsin content of histamine stimulated gastric juice GLADYS R. BUCHER *Depts. of Biological Sciences and Clinical Science, Univ. of Illinois College of Medicine, Chicago, Ill.* All but two investigators have found pepsin in histamine stimulated gastric secretion. These workers, using acutely vagotomized dogs or cats under chloralose-urethane, report that pepsin output gradually falls to zero in 5 hours of repeated or continuous histamine stimulation. We have attempted to verify their findings, which are contrary to our own on chronic dogs, but with no success. In a dog under nembutal, receiving histamine every 10 minutes, acute vagotomy in the third hour had no influence on pepsin output which remained quite uniform through the ninth hour. The experiment was repeated on another dog, using chloralose-urethane, also with no reduction of pepsin output in 3 hours after vagotomy. There was no reduction in pepsin output in 3 dogs with vagotomized total stomach pouches observed during 7 hours of repeated histamine injections when the standard dose of chloralose-urethane was given in the third hour. In two acute experiments on dogs conducted as described by Bowie and Vineberg, (*Quart. J. Exp. Physiol.* 25: 247, 1935) and three acute experiments on cats conducted as described by Uvnas (*Acta Physiol. Scand.* 4: XI, 1943) no gradual reduction in the pepsin output was observed. In 5 hours, there was a slight tendency for the output to be increased.

The use of fraction I for separation of erythrocytes and leukocytes from whole blood EDWARD S. BUCKLEY, JR., MARVIN J. POWELL and JOHN G. GIBSON, *2nd Medical Clinic, Peter Bent Brigham Hospital and the Dept. of Medicine, Harvard Medical School, Boston, Mass.* The method of Minor and Burnett (*J. Hematol.* 3: 799, 1948) has been modified for separation of red and white cells in quantities as large as 500 ml.

Fibrinogen causes rouleaux formation of red cells, with the result that, in conformance with Stokes' Law, the sedimentation rate of the clumped red cells is accelerated. Since fibrinogen affects white cells little, if at all, their sedimentation rate is not affected. Thus, addition of fibrinogen increases the differential sedimentation rates of the two classes of cells. The fraction I used contains citrate, so that no other anticoagulant is needed.

Optimal sedimentation of red cells, and hence maximal recovery of both plasma and white cells, occurs when the fibrinogen concentration of the supernatant is about 6 mg/ml, the cell-super-

natant ratio is about 0.3, and temperature between 25° C and 12° C. About 80% of plasma, containing about 80% of the total leucocytes, are obtained after 50 minutes of sedimentation.

The method described offers the possibility of obtaining red cells relatively free from white cells, and white cells free from red cells in large quantities, and hence opens the way for critical studies of the separated formed elements of the blood.

Electrocardiographic observations following explosive decompression of dogs to 30 mm Hg BUFORD H. BURCH (introduced by F. A. HITCHCOCK) *Dept. of Physiology, The Ohio State Univ., Columbus, Ohio*. In a previous communication it was reported that dogs explosively decompressed to a terminal pressure of 30 mm Hg died as a result of ventricular fibrillation which developed about 80 seconds after the explosion. This conclusion was the result of direct observation on the heart through a plastic window sutured to the anterior chest wall. The radical surgery involved may have been a factor in producing the fibrillation, and to test this possibility a series of intact anesthetized dogs were similarly explosively decompressed and continuous electrocardiograms recorded (*lead II*). About 60 seconds after the explosion, changes in rhythm were noted. A-V block, interventricular block and idioventricular rhythms occurred but no evidence of ventricular fibrillation was seen. About 2 minutes after the explosion, a severe slowing of the heart occurred. This is considered significant since previous chest window observations have shown that cessation of the heart beat occurs within 2 minutes after such explosions. Electrocardiographic deflections were observed for as long as 50 minutes after the explosion. A second series of dogs with chest windows was run and electrocardiographic observations made. With this series there was evidence of ventricular fibrillation in about 50% of the cases. It is believed that this surgical procedure tends to precipitate ventricular fibrillation. However, electrocardiographic records indicate that a sudden slowing of the electrocardiogram is the most reliable sign of cessation of the heart beat.

Effect of moderate hypoxemia, related to intracardiac venous shunts, on the systemic blood flow HOWARD B. BURCHELL, BOWEN E. TAYLOR, JULIAN R. KNUTSON and EARL H. WOOD *Div. of Medicine and Sect. on Physiology, Mayo Clinic and Mayo Foundation, Rochester, Minn.* Determinations of resting systemic blood flow and the effect of exercise on oxygen saturation of arterial blood in 16 individuals, who had moderate hypoxemia related to congenital heart disease, were analysed. The resting values for such saturation in the group averaged 82.4% (range, 75-95). The systemic blood flow averaged 3.68 l/m²/min (range, 1.6-8). No

relationship was apparent between systemic blood flow and the resting arterial oxygen saturation. The decrease in arterial oxygen saturation with exercise averaged 22% (range 10-38). The exercise tolerance was not uniformly predictable on the basis of any of the following determinations: the resting arterial oxygen saturation, the oxygen capacity, the resting systemic blood flow, or the decrease in arterial oxygen saturation with exercise. In 2 persons who exhibited, after the initial decrease, a maintained plateau of the arterial oxygen saturation with exercise, the systemic blood flow was determined during exercise. In one, the arterial oxygen saturation decreased from 95-84%, and the systemic flow/100 cc of oxygen absorbed decreased from 1.9-0.85 l/min. In the second, the arterial oxygen saturation decreased from 86-70% and the systemic flow/100 cc of oxygen absorbed decreased from 2.3-1.3 l/min. Evident simple relationships were not found between the increased systemic blood flow that may occur with the hypoxemia of congenital heart disease and the other physiologic variables which were studied.

Blood histamine in hypoxia WILLIAM L. BURKHARDT (by invitation), DON FLICKINGER (by invitation) and HARRY F. ADLER *USAF School of Aviation Medicine, Randolph Field, Texas*. The blood histamine content of dogs, as measured by biological assay, may increase 10-fold or more in response to continuous hypoxia at a simulated altitude of 18,000 ft. The increase in histamine reached a peak on the 4th day of exposure and may be correlated with the clinical appearance of the 8 dogs which at that time appeared apathetic, lethargic and had an anorexia. However, after the peak had been reached on the 4th day the histamine level began to decline until it reached a control blood level of 0.03 to 0.06 gamma per cc about 7 or 8 days later which totaled about 12 days of continuous exposure. The decrease in histamine also seemed to be correlated with clinical symptoms in that gradually over the period of the histamine decline the animals lost their apathy and began to eat normally. When the dogs were returned to ground level for 8 days a re-exposure to 18,000 ft failed to elicit the same marked degree of histamine response noted on the first exposure. However, as compared to the longer continuous exposure, a shorter 4-day exposure to 18,000 ft followed by only a 3-day rest at ground level and then re-exposure produced an exaggerated blood histamine response. The animals' weight, food intake, blood counts and hematocrits have been followed closely during the entire experimental period.

Effect of crude renal extracts and purified renin in experimental malignant renal hypertension R. O. BURNS, JR. (by invitation), W. H. JASPER (by invitation) and G. E. WAKERLIN *Dept. of Physiology, Univ. of Illinois College of*

Medicine, Chicago, Ill Crude hog renal and liver extracts and purified hog renin were injected prophylactically into dogs subjected to simultaneous bilateral renal artery constriction previously found to produce consistent experimental malignant hypertension. Injections were made daily and intramuscularly for 3 months prior to and during survival or up to one month subsequent to renal artery constriction. Crude hog renal cortex extract containing renin was highly effective in protecting against the hypertension, at least partially effective against the arteriolonecrotic lesions and partially effective in prolonging survival time. *4 dogs* Purified hog renin was only partially effective in protecting against the hypertension and the arteriolonecrotic lesions and in prolonging survival time. *5 dogs* Crude hog whole kidney extract containing renin did not have an antihypertensive effect, and was only partially effective in protecting against the arteriolonecrotic lesions and in prolonging survival time. *4 dogs* Crude hog liver extract had no antihypertensive effect and was doubtfully effective in protecting against the arteriolonecrotic lesions of malignant hypertension and in prolonging survival time. *3 dogs* The mechanism of the antihypertensive effect is not yet determined. Antirenin may be involved. The mechanisms of the protection against arteriolonecrotic lesions and the prolongation of survival time remain to be determined. Present evidence suggests the possibility that the arteriolonecrotic lesions may be due to a renal necrotizing substance which is not renin. (A method which will produce consistent experimental malignant hypertension in the dog has been devised.)

LD-50 studies on hydroquinone HELEN BURSON (by invitation), N. R. BREWER (by invitation) and A. J. CARLSON *Physiology Lab., Univ. of Chicago, Chicago, Ill.* In rats the LD-50 of hydroquinone varied with the state of nutrition of the animal and the strain of rats. LD-50 of the Priestly strain was 1317 mg/kg, the Sprague-Dawley strain, 1133 mg/kg, and the Wistar strain, 770 mg/kg.

When the rat is in the fasting state (18 hr or more without food) the LD-50 is markedly lowered. Variations that are apparent in well nourished rats of various strains become minimized or absent when the rats are fasted. The fasted Sprague-Dawley rats had an LD-50 of 319 mg/kg. The fasted Wistar rats had an LD-50 of 313 mg/kg. Animals in the fasting state show more uniform LD-50s, but this seems not significant in this study, because when added to food fats as an antioxidant hydroquinone will never be consumed in the fasting state.

When fed adult rats are given repeated doses of 500 mg/kg of hydroquinone in propylene glycol by stomach tube the mortality, after 38 administrations, was only 7 out of 20 rats. This is supporting

evidence that 1) the toxic action of hydroquinone is not cumulative, and that 2) the LD-50 on the fasted animal is not sufficient evidence of the tolerance to this chemical as an antioxidant in food.

Two fasted dogs died after one dose of 150 mg/kg by mouth. Three dogs that were not fasted showed tremors but did not die following a single dose (by mouth) of 200 mg/kg. Four dogs that were not fasted showed similar but more severe symptoms following a single dose (by mouth) of 250 mg/kg. Two dogs were given 28 consecutive daily administrations of 100 mg/kg by mouth with the food, without noticeable effect.

The LD-50 of hydroquinone on cats in the fasting state is between 50 and 100 mg/kg. However, one young cat has to date survived for 6 weeks on 15 mg/kg by mouth, with no symptoms other than a small decrease in the rate of growth when compared to a control sib.

Effects of potassium and lanatoside-C on the failing heart in heart-lung preparations SANDOR G. BURSTEIN (by invitation), LESLIE L. BENNETT, FRANCIS E. PAYNE (by invitation), and JAMES HOPPER, JR. (by invitation) *Divisions of Physiology and Medicine, Univ. of Calif., Berkeley and San Francisco, Calif.* Dog heart-lung preparations were arranged for the continuous recording of right auricular pressure, aortic pressure, ventricular volume, and left ventricular output minus the coronary flow. Unipolar electrocardiographic tracings were taken directly from the anterior surface of the left ventricle using a wick electrode. When cardiac failure was produced by overloading the heart the administration of 16-32 mg of lanatoside-C consistently produced reduction in the right atrial pressure and in diastolic ventricular volume, and an increase in cardiac output and in aortic pressure. In four experiments the subsequent administration of potassium (as KCl) reversed the lanatoside-C effects. In five experiments the heart was not overloaded but potassium was administered to the point of production of an increased ventricular diastolic volume. In each case the subsequent administration of lanatoside-C reduced the diastolic ventricular volume. Both potassium and lanatoside-C produced prolongation of the A-V and I-V conduction times as measured from the electrocardiographic tracings. Both substances also produced displacements of the S-T segments and alterations in the T waves. The S-T segment displacements and the T wave alterations produced by a minimum effective dose of one substance could be reversed by the other if it were given in a large enough dose. It was concluded that lanatoside-C can inhibit, delay, or overcome the onset or the course of potassium-induced or overwork-induced heart failure, while high potassium levels are able to inhibit, reverse, or minimize the effects of lanatoside-C.

Alteration of neuron excitability by axon section BERRY CAMPBELL, EDGAR GASTEIGER and VERNON H MARK *Dept of Anatomy, Univ of Minnesota, Minneapolis, Minn* Associated with the chromatolysis produced by axon section is a change in the reflex pattern of the nucleus involved. Previous communications have shown the loss of the proprioceptive component of the segmental reflex, the decrease in the antidromic potential, as well as the continuance of normal conduction in the primary afferent and in the axon of the affected motor cell. This suggests a general decrease in the excitability of the neuron. The study of a pure cutaneous ('flexor') type of response, the tibial-peroneal reflex, during the chromatolytic cycle confirms this interpretation. In a series of 25 cats studied from 2 to 102 days following section of the peroneal nerve the following changes were noted: an increase in central latency, a simplification of the oscillographically recorded reflex potential curve, a decrease in amplitude and, during the height of the cycle, an absence of the reflex. The subliminal fringe, as tested by a second shock, was relatively larger in the early part of the cycle, smaller later. All effects found are consistent with a generalized decrease in excitability of the cells.

Effect of increased intracranial pressure on the circulation in relation to pulmonary lesions GILBERT S CAMPBELL (by invitation), FRANCIS J HADDY (by invitation) and M B VISSCHER *Dept of Physiology, Univ of Minnesota, Minneapolis, Minn* Studies have been made on dogs using right and left heart catheterization to measure pulmonary arterial (PAP) and venous pressures (PVP). Cardiac output, systemic arterial pressure and heart rate were also recorded. Increased intracranial pressure (IICP) was produced by inflating a balloon inserted extradurally through a small trephine opening. It was found that on the average in 18 dogs the mean PVP was 8.2 mm Hg above intrathoracic before IICP was induced. Afterward the value rose to 18.1 mm Hg. Concomitant with IICP there was bradycardia, lowered cardiac output and an elevation of PVP and PAP. Gross examination of the lungs at necropsy revealed varying degrees of pulmonary edema, congestion and hemorrhage. Atropine (1.3-1.95 mgm) was administered i.v. to 4 dogs following IICP. The control mean PVP was 5.5 mm Hg prior to IICP and the PVP following IICP was 13.9 mm Hg. The IICP was maintained following the administration of atropine, and the mean PVP fell to 6.6 mm Hg within 3 minutes. Atropine produced a tachycardia, raised the cardiac output to its control level and apparently protected the animals from the more severe pulmonary edema, congestion and hemorrhage encountered in the earlier group of 18 dogs which were not given atropine. There was no

correlation between systemic arterial pressure and these effects.

Effects of an anterior pituitary extract on the metabolism of the liver JAMES CAMPBELL and I W F DAVIDSON (by invitation) *Dept of Physiology, Univ of Toronto, Toronto, Canada* The effect of an extract of the anterior pituitary gland on the metabolism of the liver was studied by administering the extract to fasting rats and determining the rate of oxygen uptake and the production of acetoacetic acid by liver slices *in vitro*. These determinations were made at intervals throughout 6 days of fasting and treatment with the extract ($Q_{O_2}^t$ and Q_{aa}^t signify the μ l oxygen taken up and the μ g acetoacetic acid produced, respectively, per mg total solids of liver per hour). In the 24 hours following the first injection the $Q_{O_2}^t$ was less in the injected than in the control animals, but when recalculated on the basis of fat-free solids ($Q_{O_2}^f$) the values in the pituitary-treated animals were greater. After this 24-hour period both the $Q_{O_2}^t$ and Q_{aa}^t values were greater in the treated animals. The influx of lipid into the liver produced by the fat-mobilizing stimulus of the pituitary extract accounts for this inversion of the relationship during the first 24 hours. The Q_{aa}^t and Q_{aa}^f values were greater in the injected animals from the start of the experiment. The evidence indicates that a pituitary factor caused an enhanced activity of the fat-metabolising system of liver tissue. The oxygen uptake and the acetoacetic acid production by the liver per 100-gm body weight were increased by administration of the extract. The addition of octanoate to the liver slices *in vitro* produced an increased oxygen uptake and acetoacetate production, and the extra oxygen taken up in the presence of the substrate could be accounted for by the amount of extra acetoacetate formed. The liver slices from the treated animals had an enhanced ability to produce acetoacetate from the added substrate.

Parathormone and the tubular reabsorption of glucose and phosphate in man WALTER H CARGILL and A CALHOUN WITHAM (introduced by JAMES V WARREN) *Depts of Physiology and Medicine, Emory Univ School of Medicine, and the Medical Service, Lawson Veterans Administration Hospital, Atlanta, Ga* It is well known that the urinary excretion of phosphate may be increased by the administration of parathyroid hormone and decreased by the ingestion or infusion of large amounts of glucose. We have investigated the role of tubular activity in these reactions in normal human subjects. Glomerular filtration rate was determined by inulin clearance and the rates of reabsorption of glucose and phosphate obtained as the difference between the rates of filtration and excretion. Since the intravenous injection of parathormone (200-400 i.u.) did not alter filtration rate,

the increased excretion of phosphate which followed was due entirely to decreased reabsorption. The reabsorption of glucose usually decreased also. When the rate of glucose reabsorption was increased by the intravenous infusion of 10% glucose solution there was a corresponding increase in phosphate reabsorption, in addition to a decreased rate of phosphate filtration resulting from a lowered plasma level. The injection of parathormone during or immediately following the glucose infusion produced a further increase in the rate of phosphate reabsorption. These observations suggest that the mechanisms of tubular reabsorption of phosphate and glucose are closely related, and that during periods of increased glucose reabsorption the usual effect of parathormone on phosphate excretion may be reversed.

Delay of senescence infertility by dietary restriction CLAIRE J. CARR (by invitation), JOSEPH T. KING and M. B. VISSCHER *Dept of Physiology, Univ of Minnesota, Minneapolis, Minn.* A group of C₃H female mice have been studied in detail for 23 months. Ten of the original 17 are now living. Since it was known that restriction to 66% of normal calories would disturb but not prevent normal estrous cycles, these mice were restricted to 50% of a normal caloric intake. Protein, minerals and vitamins were not restricted. They remained in anestrus. Occasionally a mouse would show a subestrus response. At two different intervals several mice were given fresh pituitary implants; they responded promptly with a positive vaginal smear. After 14 months half of the group was given increasing caloric supplement with dextrose. Some mice developed positive smears with as little as 0.150 gm dextrose while others required as much as 1.0 gm. At 21 months the whole group was fed *ad libitum*. Within a week all showed positive smears. At this point they were tested with fertile males. All became pregnant. Some aborted at about the 15th day but subsequently delivered litters. To date the litters have not survived, apparently due to failure of lactation. Observations are being continued. It is apparent that prolonged, severe caloric restriction delays the onset of infertility to a very advanced age. Strain A mice restricted until 8 months old have been studied previously (Ball, Barnes and Visscher, *Am J Physiol* 150: 511, 1947).

Resistance induced by anti-thyroid compounds and by goitrogenic diets against experimental pulmonary edema in rats K. K. CARROLL (by invitation) and R. L. NOBLE *Dept of Medical Research, Collip Medical Research Lab, Univ of Western Ontario, London, Canada.* ANTU (α -naphthylthiourea) and several closely related compounds have been shown to possess a high toxicity specific for rats. Pretreatment of rats with sub-lethal doses of ANTU induces a marked re-

sistance to its toxic action (Richter 1945, 1947). The present study has demonstrated that resistance to ANTU can also be produced by pretreatment with various other compounds containing the thiourea grouping. Neither the anti-thyroid potency nor the acute toxicity of these substances is directly related to their ability to impart resistance. In addition, resistance to ANTU is found in rats fed on certain goitrogenic diets, especially those containing seeds of the *Brassica* species. This effect has been used as an assay in preparing active extracts of rape seed. Details of the extraction procedure are discussed.

Connective tissue and parenchymal changes in ovary of the rat H. R. CATCHPOLE and S. C. PAN (by invitation) *Dept of Pathology, Univ of Illinois College of Medicine, Chicago, Ill.* Two methods were applied to the study of ovarian connective tissue in immature female rats which were treated with 2-25 RU of equine gonadotrophic hormone and examined after 6-60 hours. Animals of control groups and of groups so stimulated received an injection of 0.5 ml 1:25% Evans blue (intravital) dye intravenously 10 minutes before death. Their ovaries were frozen in liquid air and frozen-dried *in vacuo*. They were then embedded in paraffin, sectioned at 30 μ , mounted in mineral oil and examined directly. Ovaries from control and gonadotrophin-treated animals were frozen-dried, sectioned at 6 μ and stained by the McManus-Hotchkiss periodic acid-leucofuchsin technique for glycoproteins. Young adult female rats at different stages of the cycle were also studied by the above techniques. In the normal rat, the extracellular distribution of Evans blue duplicates that of glycoproteins staining with the periodic acid-leucofuchsin method. There is an increased staining density of glycoprotein at pro-estrous and estrous, which is even more pronounced following gonadotrophin stimulation. Coincidentally, more Evans blue is visible in the connective tissue of stimulated ovaries compared either with controls or with normal cyclic ovaries, and the increase is proportional to the dosage or time of action of the hormone. Increased binding of Evans blue and staining density with the McManus-Hotchkiss reagent are interpreted as due to a process of depolymerization occurring in glycoprotein components of the connective tissue. These changes are thought to underlie, or to favor, structural rearrangements within the ovary occasioned by follicular growth.

Studies on bound acetylcholine DANIEL J. CAVANAUGH and JULIAN M. TOBIAS *Dept of Physiology and Toxicity Lab, Univ of Chicago, Chicago, Ill.* The coexistence of bound acetylcholine (ACh) and cholinesterase (ChE), and, in some cases, of large amounts of free ACh and active ChE (*J Cell Comp Physiol* 28: 159, 1946) in

tissue stimulates one to ponder why the enzyme does not hydrolyze the substrate *in vivo*. A variety of possibilities exists. There may be a steady state of interaction appearing to be lack of interaction, the enzyme may be in inactive form, the enzyme and substrate may be separated by a structural barrier, one or the other may be held in an inaccessible state, as by adsorption etc. Toward clarifying this situation, preliminary experiments have shown that adsorption of ACh on charcoal can protect it from demonstrably active ChE. It has also been found, using rat brain preparations, that thermal liberation of free ACh from bound precursor is rather rapid, even at relatively low temperatures, being 50% complete in 1 hour or less at 15°C. The rate of unbinding between 15–40°C is markedly accelerated over that at 0–15°C. Such adsorption protection of ACh from ChE *in vitro* and the relative ease of thermal dissociation of precursor are facts compatible with the notion that bound ACh is loosely held in precursor.

It has also been found that in a distilled water homogenate of brain (rat) the bound ACh is not thrown down at centrifugal speeds something over 20,000 r p m. It is either water-soluble or highly disperse, not associated with the denser protoplasmic constituents under these circumstances, and can be shown to be associated with a high lipid content fraction of the brain.

Effect of a psychiatric interview on renal plasma flow and finger skin temperature. JAMES H. CHALMERS (by invitation), ROBERT W. CRANSTON (by invitation), HENRY LONGSTREET TAYLOR and ANCEL KEYS *Laby of physiological hygiene, Univ of Minnesota, Minneapolis, Minn.* Thirty-eight experiments were conducted on 27 well adjusted healthy males and females ranging in age from 20–62 years, all of whom were free of cardiac and renal abnormalities. The subjects were divided into 4 groups on the basis of age and sex. Observations were made of renal plasma flow and skin temperature during a restful control period followed by a period during which emotionally charged topics were intentionally introduced by a psychiatrist familiar with the emotional backgrounds of the subjects. This resulted in moderate emotional tension in most subjects. No marked reactions were noted. A control group was studied by identical methods in which no emotional stimuli were applied. The intraindividual standard deviation of renal plasma flow of the control group (11 experiments on 6 young males) for the periods corresponding to the psychiatric interview was used to calculate T scores for evaluating the response of each of the other subjects to the psychiatric interview. Highly significant changes in renal plasma flow (T score greater than 3) occurred during the interview in 4 of 11 experiments on 7 young males, 5 of 8 experiments on 8 older males and 4 of 8 experi-

ments on 6 females. Positive as well as negative deviations from basal values were found. The degree and duration of emotional response elicited varied between individuals and in the same individual on different occasions. Significant changes in skin temperature of the finger occurred during the interview but were not correlated with changes in renal plasma flow.

Pressure changes and hemorrhage in the middle ear of monkeys resulting from decompression and recompression. HSIANG-TUNG CHANG (by invitation), RODOLFO MARGARIA (by invitation) and SAMUEL GELFAN *Laby of Physiology, Yale Univ School of Medicine, New Haven, Conn.* The pressure changes developed in the middle ear during decompression and recompression have been directly determined by means of a membrane-mirror manometer and recorded photographically. The middle ear pressure increases proportionally with gradual reduction of ambient pressure, the expanding air in the tympanic cavity escaping periodically through the Eustachian tube. The average differential pressure required for forcing the Eustachian tube open in anesthetized monkeys was found to be between 10 to 13 mm Hg. At the instant of explosive decompression the positive pressure in the middle ear increases suddenly to a value which tends to approach the pressure difference between the pre- and post-decompression altitudes. This excess middle ear pressure, however, is very quickly reduced to that of the ambient pressure.

During recompression anesthetized monkeys are unable to equalize the ambient and middle ear pressures, the negative pressure developing in the middle ear increasing with increasing ambient pressure. This negative pressure, after reaching a critical value, will cause traumatic lesions. Autopsy of explosively decompressed monkeys showed severe bleeding in the tympanic cavity and the mastoid cells of the temporal bone with the ear drum remaining intact. Puncture of the ear drum prior to decompression prevents the tympanic hemorrhage.

Artificial insemination of rabbits and transplantation of rabbit eggs (motion picture). M. C. CHANG and G. PINCUS *Worcester Foundation for Exptl Biology, Shrewsbury, Mass., and Tufts College of Medicine, Boston, Mass.* The pictures of Spallanzani (first successful artificial insemination of dogs in 1785), Heape (first successful transplantation of rabbit eggs in 1890), Hammond and Walton (who developed the technique of artificial insemination of rabbits), and Pincus (who developed the technique of transplantation of rabbit eggs) are shown. Methods of rabbit semen collection by means of a piece of rabbit skin and artificial insemination of the rabbit are photographed in color. The recovery of rabbit eggs from excised

oviducts and from the living animal by a surgical method are demonstrated. Living rabbit eggs in the four-cells stage are photographed. Surgical methods for transplanting rabbit eggs at early stages into the oviducts, and blastocysts into the uterus of recipient rabbits are shown. The storage of eggs at low temperatures and the probability of eggs (recovered at different stages, and stored at various temperatures for different lengths of time) developing into normal young rabbits are described. Albino young produced from black chin-chilla foster mothers are photographed. A historical review of sperm study and the development of artificial insemination for livestock improvement are shown in a chart. The egg study and the possibility of egg transplantation for the full utilization of female germ cells of valuable animals are illustrated for livestock improvement.

Effect of substrate concentration on the luminescent reaction of Cypridina luciferin and luciferase AURIN M CHASE *Physiological Laby, Princeton Univ, Princeton, N J, and the Marine Biological Laby, Woods Hole, Mass*. It has been stated (Moelwyn-Hughes, *Ergeb der Enzymf* 6 23, 1937) that the Michaelis constant, K_s , for the luminescent reaction of Cypridina luciferin and luciferase has a negative, and therefore theoretically meaningless, value. For this reason he analyzed and satisfactorily interpreted this reaction in terms of chain reaction theory. Since the data used by Moelwyn-Hughes represented the velocity constant rather than the initial velocity of the reaction as a function of luciferin concentration, a determination of the relationship between velocity of the luciferin-luciferase reaction and the initial luciferin concentration was undertaken in order to obtain data suitable for analysis in terms of the Michaelis-Menten theory of intermediate enzyme-substrate complex formation. It was found that the initial velocity increases asymptotically to a maximum value as luciferin concentration is increased, yielding data quite susceptible to analysis in terms of the Michaelis-Menten theory. Two enzyme concentrations were used and a 200-fold range of substrate concentration was studied. Excellent agreement with the Michaelis-Menten equation was observed and the calculated value of K_s , the dissociation constant for the luciferin-luciferase complex, was about 6×10^{-7} (the molar luciferin concentration giving $\frac{1}{2}$ maximum velocity). This order of magnitude is similar to those found for many oxidative enzyme systems which have been studied. The analysis of the data further indicated that one luciferin molecule combines with one luciferase molecule in the formation of the enzyme-substrate complex.

Effect of desoxycorticosterone acetate (DCA) on pituitary content of adrenocorticotrophic hormone (ACTH) after adrenalectomy CHI-PING

CHENG (by invitation), MARION A SAYERS (by invitation) and GEORGE SAYERS *Dept of Pharmacology, Univ of Utah College of Medicine, Salt Lake City, Utah*. The content of ACTH in the pituitary of the rat is reduced to $\frac{1}{2}$ of normal 24 hours after adrenalectomy (Cheng and Sayers, *Proc Soc Exptl Biol & Med*, in press). Six of 12 rats were implanted with six 15 mg pellets of DCA each, 48 hours later, all 12 were adrenalectomized. Twenty-four hours later, the rats were killed and the pituitaries removed. Pituitaries were also removed from untreated intact controls and from 6 intact rats 72 hours after the implantation of DCA (six 15 mg pellets each). The anterior lobes were frozen and lyophilized and the dried glands of each group pooled and ground to a homogeneous powder. The concentration of ACTH in the powders was determined by the adrenal ascorbic acid-depletion method. DCA had no effect upon the content of ACTH in the pituitaries of the intact rats. The content of ACTH in the pituitaries of the untreated adrenalectomized rats was 15% while that of the DCA-treated adrenalectomized rats was 43% of the control level. In animals with intact adrenals, non-specific stress (scald, sham-adrenalectomy) reduces the ACTH content of the pituitary by 50%. It may be concluded that DCA prevents the marked depletion of pituitary ACTH which normally follows the complete absence of adrenal cortical secretions. The results lend additional support to the concept that pituitary adrenocorticotrophic activity is regulated by the level of cortical steroids in the body fluids.

Order of recovery from excitation in dog, monkey, and human heart, nature of ST-segment and T-wave H M CHERNOFF (by invitation) and L H NAHUM *Laby of Physiology, Yale Univ School of Medicine, New Haven, Conn*. The recovery process in mammalian ventricle was studied by a) forced extrasystoles, b) heating and cooling regions of the dog ventricle, c) high altitude anoxia in monkeys and d) simultaneously recorded unipolar extremity and precordial leads in man. Practically all normal subjects show in some leads displacement of ST in the same direction as the T-wave. All extrasystoles exhibit similarly displaced ST segments. High altitude anoxia causes similarly displaced ST-segment and QT shortening. Heating localized ventricular areas produces QT shortening and similar ST-segment displacement. Cooling localized areas lengthens QT and produces ST-segment displacement in same direction as T, but displacement is opposite to that produced by heating same area. ST displacement and T-wave direction in each lead depends upon region of heart whose repolarization has been altered.

In dog, monkey and human heart repolarization is already in progress at end of S. An isoelectric

ST results from balanced repolarization in proximal and distal zones of that lead. The T-wave represents that part of the repolarization process in which the greatest imbalance of potential exists between proximal and distal zone. First stage anoxia causes accelerated repolarization, which is reflected by a specific ST-T pattern. In dog and human heart, the apical and diaphragmatic regions are the earliest to repolarize.

Vasomotor side effects of two new amines which primarily depress intestinal motility. J. R. CHITTUM, F. H. LONGINO and B. H. METCALF (introduced by K. S. GRIMSON) *Dept of Surgery, Duke Univ, Durham, N. C.* Vasomotor actions of a tertiary amino compound, dibenzylmethyl B-diethylaminopropionate hydrochloride (SC1870), which reportedly has five times the activity of papaverine in relaxing barium-induced spasm have been compared with those of a quaternary amine, ethyl dimethyl B-(9-xanthene carboxylate) ethyl ammonium chloride (SC1703), which reportedly inhibits autonomic ganglia and also has twice the anti-acetylcholine activity of atropine. Five to 7.5 mg/kg of 1870 or 2.5 to 4 mg/kg of 1703 delayed gastric emptying and reduced transit time through the ileum of unanesthetized dogs. Essentially similar doses of either drug produced reduction of blood pressure with little change or decrease of pulse rate in dogs anesthetized using chloralose. After either drug the effect of stimulation of distal ends of divided vagi upon heart rate was prevented. During the period of hypotension following either drug, increase of blood pressure normally caused by occlusion of carotid arteries did not occur. Following effective doses of either drug, anoxia failed to increase blood pressure. Stimulation of the central end of a divided vagus nerve after 1870 did produce marked increase of blood pressure. After 1703, however, the pressor response to central vagus stimulation was blocked. After either drug adrenalin increased blood pressure and heart rate. Experiments indicate that both drugs have definite vasomotor effects when given in large doses. These doses, however, apparently were well tolerated when given intravenously to unanesthetized dogs during ileal studies.

Studies of the use of intravenous quinidine orally in certain mechanism disorders. JOHN W. CHRISS (by invitation), MILTON R. HEJTMANCIK (by invitation) and GEORGE R. HERRMAN. *Univ of Texas Medical School, Galveston.* Quinidine is almost a specific drug for the interruption of serious disorders of the cardiac mechanism such as ventricular tachycardia, atrial fibrillation and atrial tachycardia. In most of our cases the sino-atrial rhythm was reestablished after 1-8 oral doses of 0.2 gm of quinidine sulfate. In rare cases that proved refractory to oral therapy the seriousness of the patient's condition was such that heroic introduction of quinidine lactate was

resorted to. We are fully cognizant of the dangers of using quinidine intravenously and certainly proceeded with great caution. Intravenous quinidine lactate and sulfate were used in several cases of ventricular tachycardia, atrial flutter, atrial tachycardia and atrial fibrillation. The few cases in which even heroic therapy failed will be discussed along with those successfully treated.

The 'motor' cortex of the dog. J. G. CHUSID (by invitation), C. G. DE GUTIERREZ-MAHONEY and FRANKLIN ROBINSON (by invitation) *Neurological Division, St. Vincent's Hospital and Lab of Physiology, Yale Univ School of Medicine, New Haven, Conn.* The cerebral cortex of 19 dogs under light Dial-urethane anesthesia was stimulated manually using bipolar Ag-AgCl electrodes and a Goodwin stimulator. 'Buried' cortex, exposed by subpial suction of tissue, was explored and found to resemble in its motor characteristics the adjacent exposed cortex. The inferior bank of the coronal sulcus was found to be the superior limit of the 'face' area, while the superior bank of the coronal sulcus was found to be the inferior limit of the 'arm' area. The posterior bank of the presylvian sulcus was found to be the anterior limit of the 'face' area, and in its inferior orbital portion was found to inhibit respiration readily. Although a relatively wide representation for 'face' and its subdivisions was apparent, repeated stimulation of this area and the adjacent posterolateral cortex failed to evoke leg or arm movements. The posterior bank of the cruciate sulcus represented the anterior limit of the 'leg' area. Extension of the 'arm' area onto the anterior bank of the cruciate sulcus occurred in its most lateral portion. Eye movements, pupillary changes and tearing were evoked from the 'buried' cortex of the presylvian sulcus in its most medial (midline) portion. Stimulation of the adjacent cortex lying medially and extending for several millimeters onto the medial aspect of the hemisphere produced the most pronounced pupillary changes; stimulation of the anterior cingulate area inhibited respiration.

Effect of intravenous injection of hypertonic saline on salivary secretion in dogs. L. J. CIZEK (by invitation) and M. I. GREGERSEN. *Dept of Physiology, College of Physicians and Surgeons, Columbia Univ, New York City.* Many investigators have shown that thirst can be induced by the intravenous injection of hypertonic salt solution. Holmes and Gregersen (*Am J Physiol* 151:252, 1947) demonstrated that the thirst so produced in man was associated with a reduction in the overall salivary secretion. This prompted us to study salivary secretion in the unanesthetized dog before and after the intravenous injection of 20% NaCl (2 cc/kg). Observations were made on 6 dogs, 3 with submaxillary fistulas and 3 with parotid fistulas. Panting in a hot box was used as a uni-

form stimulus. The submaxillary secretion was either unaffected or somewhat augmented by the injection of hypertonic saline. However, the parotid secretion, which was comparatively small but surprisingly constant during the control periods, was sharply reduced or completely absent after saline injection. The difference in response of the two types of glands is unexplained. Furthermore, the evidence so far on the dog is not conclusive in showing that the total secretion into the mouth is reduced by hypertonic saline, although that would be the inference from results on man and from the fact that intravenous saline causes both man and dog to drink.

Responses elicited by combined stimulation of pairs of fixed electrodes in the unanesthetized monkey. GEORGE CLARK and JAMES W. WARD (by invitation). *Dept. of Anatomy, Chicago Medical School, Chicago, Ill., Yerkes Labs. of Primate Biology Inc., Orange Park, Fla. and Dept. of Anatomy, Vanderbilt Medical School, Nashville, Tenn.* Electrodes were implanted aseptically upon the Betz cell area, premotor area and eye fields in each of 10 immature monkeys (*Macaca mullatta*). Selected pairs of these electrodes were stimulated with 60-cycle sine wave current either consecutively or concurrently. As compared to the effects of single stimulation the responses were either unchanged or augmented. In no case did suppression occur. It is suggested that both inhibitory and facilitatory processes may be induced by appropriate cortical stimulation and that under different physiological conditions of the animal, one or the other may be elicited.

Effect of work on renal oxygen utilization. JOHN KAPP CLARK and HAROLD G. BARKER (introduced by J. R. ELKINTON). *Dept. of Medicine and Harrison Dept. of Research Surgery, School of Medicine, Univ. of Pennsylvania, Philadelphia, Pa.* No change in renal oxygen utilization was demonstrated in 15 normal human subjects between basal states and conditions of probably changed renal work, namely saturation of PAH transport mechanism, water diuresis, osmotic (Mannitol) diuresis, 5 subjects each. Arterial and renal venous (catheter) blood was sampled simultaneously. Flow was calculated from the Fick equation using PAH. Oxygen content was determined manometrically and corrected for A-V differences in hemoglobin content. The product of blood flow and A-V difference represents oxygen utilization. 300 gm. of kidney tissue were assumed equivalent to 1.73 square meters surface area. Blood flow remained essentially constant during the tests. The mean control value for oxygen utilization in all 15 patients was 6.1 cc/100 gm/min (standard deviation ± 2.27 , standard error of the mean $\pm .607$). In 12 of the 15 cases no change over 1.5 cc/100 gm/min was observed.

TEST	OXYGEN UTILIZATION CC/100 GM /MIN	
	Mean Change	Range
PAH saturation	0.1	(-2.0 to +4.7)
Water diuresis	0.7	(-4.4 to +1.2)
Mannitol diuresis	0.4	(-1.0 to +1.4)

Small A-V oxygen differences make the experimental error large. Nevertheless the kidney seems not to vary its oxygen utilization with increased functional activity to a degree comparable to other organs or to the body as a whole where utilization may increase 16 fold during exercise.

Oxidation of CO to CO₂ by the intact animal. ROBERT T. CLARK, JR., J. NEWELL STANNARD and W. O. FENN. *Depts. of Physiology and Vital Economics, and of Radiation Biology, Univ. of Rochester School of Medicine and Dentistry, Rochester, N. Y.* Previous experiments with isolated frog tissue in a respirometer containing 80% CO and 20% O₂ indicated that CO in this mixture invariably stimulated gas uptake in heart and skeletal muscle as compared to the rate in air. By direct analyses of the respired CO₂ using radioactive C¹⁴, this apparent stimulation was shown by us to be due to the oxidation of CO to CO₂ by the muscles. To determine whether CO would be burned in the intact animal, turtles and mice were placed in concentrations of CO in air ranging from 0.02-0.07% in air-tight containers. The amount of CO oxidized was determined by 1) measuring by a modification of the Roughton-Root technique the drop in CO concentration in the air during the experimental period and 2) determining the amount of C¹⁴O appearing as C¹⁴O₂ in the expired air. The gasometric measurements showed that considerably more CO disappeared in the presence of the animals than in the control period. In 10 days the turtles oxidized 52% of the CO present, while mice utilized CO at the rate of 0.044 mm³/g/min. Two independent measurements on mice with collection of C¹⁴O₂ indicated the rate of 0.0049 mm³/g/min. This rate of burning was greater by a factor of 10 than would be expected by extrapolation from the rate observed with isolated tissues in 80% CO and 20% O₂. Extrapolation of these rates to man would indicate oxidation of 20 cc CO per hour after breathing air containing 0.07% CO.

Occurrence of gastric secretory inhibitor activity in fresh gastric and salivary mucin. CHARLES F. CODE, HENRY V. RATEK (by invitation), GEORGE R. LIVERMORE, JR. (by invitation), and WALTER LUNDBERG (by invitation). *Section on Physiology, Mayo Foundation, Rochester, Minn., and Hormel Inst., Univ. of Minnesota, Minneapolis, Minn.* It was shown some years ago by Brunschwig and his co-workers that the intravenous in-

jection of gastric juice or alcoholic precipitates of gastric juice obtained from patients with achlorhydria produced an inhibition of the gastric secretory response of dogs to a meat meal. This observation was confirmed and extended by Blackburn and one of us (Code). They found that the inhibitor activity was associated with the mucin fraction of gastric juice, and that it was present in samples of commercial gastric mucin, whereas it was absent in preparations of pepsin.

In the present study, fresh gastric mucin was obtained by scraping the mucosa of the stomachs of hogs immediately after killing. The intravenous injection of physiologic saline extracts of this material consistently eliminated the acid gastric secretory response of dogs to rather large doses of histamine given subcutaneously every 10 minutes. The inhibitor activity was found to be precipitated by alcohol. Alcohol precipitates of saliva, like those of gastric mucin, may produce inhibition of the acid gastric secretory response to histamine, but the degree of inhibition produced by salivary preparations thus far has been less than that associated with preparations of gastric mucin. Immediate reactions, manifested often by weakness and a decrease of blood pressure and delayed reaction as indicated by emesis and an increase in temperature may occur when preparations of mucinogenous materials are injected intravenously into dogs. Although inhibition of gastric secretion has been observed in the absence of such reactions, the significance of the occurrence of these reactions in relation to the gastric secretory inhibitor activity of the preparations is not fully understood.

Renal clearances in normal dogs receiving desoxycorticosterone acetate. W. D. COLLINGS, C. F. DOWNING (by invitation) and R. E. HODGES (by invitation). *Dept. of Physiology, State Univ. of Iowa, Iowa City, Ia.* During the course of some studies of renal-adrenal relationships in dogs, it was necessary to investigate the effects of desoxycorticosterone acetate (DCA) on normal dog kidney function. Preliminary studies were made of creatinine and para-aminohippuric acid (PAH) clearances in 3 trained female dogs before, during and after treatment with DCA. Clearances were done by the usual technique of priming the animals first, then maintaining plasma levels of the cleared substances by constant intravenous infusion. Urines were obtained by catheter, and usually three consecutive 15-minute collection periods were run. Rates of urine flow obtained were 2-4 ml/min. The mean control clearances for 79 clearance periods were creatinine, 55.8 ml/min and PAH, 196.8 ml/min. The mean values for 21 clearances done while the dogs were receiving 2.5-7.5 mg DCA daily for 5-7 days were creatinine, 66.5 ml/min and PAH, 191.8 ml/min. Mean values for 26 clearances at daily DCA doses of 10-15 mg

for 6-7 days were, creatinine, 74.8 ml/min and PAH, 260.3 ml/min. Although other possibilities cannot be ruled out, increased clearances with higher doses of DCA may be related to hemodynamic effects of altered circulating blood volume. On higher DCA doses the classical changes were present, i.e. hemoglobin and hematocrit were reduced whereas both systolic and diastolic blood pressures were slightly elevated.

Cytological effect of slow neutrons. ALAN D. CONGER (introduced by ALEXANDER HOLLANDER). *Biology Division, Oak Ridge National Lab., Oak Ridge, Tenn.* The operation of chain reacting atomic piles has made a new type of radiation, slow neutrons, available in amounts large enough for considerable biologic effect and possible damage. The biologic effect of the non-ionizing slow neutrons is produced indirectly when they are captured by atoms which then emit the various ionizing radiations. Most important reactions in biologic materials are hydrogen capture of slow neutrons, forming deuterium which immediately emits a gamma ray, and nitrogen capture with the emission of a proton. The action of slow neutrons in causing a specific biologic effect, the breakage of chromosomes, has been studied in the flowering plant *Tradescantia*. Such broken chromosomes are lethal to cells possessing them when those cells subsequently divide, slow neutron exposures of about 15 minutes produced visible aberrations in 50% of the cells. Previous experiments on the same plant have shown that certain types of these chromosome breakage aberrations increase as the dosage squared when x- or gamma-radiation is used, but increase linearly with dose when a radiation of heavy particles is used. The chromosome breakage data from slow neutron treatment given in the Oak Ridge Pile show a linear increase with dose, indicating that the most important reaction of slow neutrons in this tissue is the nitrogen capture with its emission of a proton.

Cardiovascular effects of nembutal, dibenamine and yohimbine on trained dogs. GEORGE CONSTANT (by invitation), ARISTOPHANES ANDRONIS (by invitation) and ERIC OGDEN. *Dept. of Physiology, Univ. of Texas Medical Branch, Galveston, Texas.* Arterial pressure of trained dogs was measured by femoral puncture with a needle connected to a Tyco's manometer, the lowest point of the excursion being recorded. Such readings are a few millimeters above diastolic pressure. The drugs were given slowly intravenously in normal saline solutions. Nembutal (30 mg/kg) greatly increased pulse rate and affected blood pressure variably, a fall being usual. These effects lasted from 1 to 4 hours. Dibenamine (25 mg/kg) lowered the blood pressure and its effect on the pulse rate was variable, since intravenous dibenamine caused much distress and struggling these pulse rate de-

terminations are doubtful, therefore only 3 such experiments were done. Dibenzamine during Nembutal anesthesia produced a further decrease in blood pressure but slowed the pulse rate, not however to the pre-anesthetic level. Yohimbine raised the pulse rate and usually lowered the blood pressure of unanesthetized dogs. Yohimbine given to the nembutalized animal raised both blood pressure and pulse rate. These observations serve again to emphasize the difficulties of interpretation of observations of the cardiovascular system made under anesthesia. The detailed pharmacodynamic interpretation of these differences should not be attempted until a great variety of simultaneous measurements of different cardiovascular functions is available.

Proteolytic activity in cerebro-spinal fluid

GEORGE CONSTANT (by invitation), WIKTOR W. NOWINSKI, ROBERT B. WHITE (by invitation) AND JOY M. HART (by invitation) *Tissue Culture Lab and Dept of Neurology and Psychiatry, Univ of Texas Medical Branch, Galveston, Texas*. Cerebro spinal fluid from schizophrenic and neurotic patients was investigated for its proteolytic activity. This was measured by the release of tyrosine and tryptophane during incubation for 3 hours at 37°C with edestine as substrate and at a final pH 4.2. Controls were set up by incubating cerebro-spinal fluid without substrate, but under the same conditions. The estimation of released amino acids was carried out with Folin-Ciocalteu reagent using a Beckman spectrophotometer and the figures obtained were related to a standard expressed in milligrams tyrosine. It was found that in 35 of the 38 cases investigated the amount of released tryptophane and tyrosine in the spinal fluid of these individuals was 40 to 70% greater as compared with the control tubes which did not contain the substrate.

Some methods of producing traveling contraction nodes in adult frog muscle fibers (motion picture) B. A. COOKSON and FLOYD WIERCINSKI (introduced by L. V. HEILBRUNN) *Depts of Zoology, Univ of Pennsylvania, and of Physiology, Hahnemann Medical School, Philadelphia, Pa*. Small bundles of muscle fibers, teased from the adductor magnus of *Rana pipiens*, were immersed in a solution containing 1.3% NaCl and 0.75 vols % H_2O_2 . After approximately 2 minutes small contraction nodes were seen forming in various regions of the fibers. These nodes usually recurred in the same regions at regular intervals. After originating, they traveled along the fibers. Usually the node as it formed split into two nodes traveling in opposite directions. Frequently the nodes collided and canceled out. Sometimes contraction nodes were formed which involved only half the circumference of the muscle fiber. A slight increase in the H_2O_2 concentration produced, instead of traveling

nodes, large stationary areas of fiber which rhythmically contracted and relaxed. During the contraction the sarcolemma became wrinkled. A slight decrease in the H_2O_2 concentration resulted in complete absence of response. Reduction of the NaCl concentration to 65% (approximately isotonic), also resulted in an absence of response. A solution containing 1.3% NaCl, 0.75 vols % H_2O_2 , 1% glutathione and enough 0.1 N NaOH to adjust the pH to 7.4 was found to keep its potency for over 2 days, whereas the solution containing only 1.3% NaCl and 0.75 vols % H_2O_2 , due to the instability of the H_2O_2 , remained potent for only 2-3 hours. With the former solution it was possible to produce traveling contraction nodes in isolated single fibers with injured ends. Preliminary studies indicate that traveling contraction nodes can also be produced by solution of 2-methyl 1,4 naphthoquinone in Ca-free frog ringer.

Osmophilia in relation to alkaline phosphatase activity in the chloride cell (gill) of fundulus heteroclitus D. EUGENE COPELAND (introduced by C. M. WILLIAMS) *Arnold Biological Lab, Brown Univ, Providence, R. I*. Evidence has been previously presented (Copeland, *J. Morph.* 82) of a cell type responsible for the salt excretion described by Smith (*Am. J. Physiol.* 93) as occurring from the gills of marine fish. Subsequently it was suggested (Pettengill and Copeland, *J. E. Z.* 108) that the marked increase in phosphatase activity found when *F. heteroclitus* is adapted to fresh water indicated a physiological reversal of cell polarity, the cell then becoming an absorptive mechanism, accounting for the chloride absorption noted by Krogh (*Z. vergl. Physiol.* 24) in fresh-water fishes. In the present report, a similar marked increase in osmophilia is found to occur as the fish becomes fresh water adapted. Emmel (*Anat. Rec.* 91) has shown a positional relationship of phosphatase activity and Golgi zone in the absorption cells of the intestine. The chloride cell not only shows a reasonable positional similarity of the two phenomena but also a synchronous change in amounts with change in functional activity of the cell.

Ferritin effect on blood pressure and pressor response in rats A. C. CORCORAN, G. MASSON and C. SCHAFFENBURG (by invitation) *Research Division and Bunts Inst of the Cleveland Clinic Foundation, Cleveland, Ohio*. A sample of ferritin was kindly supplied us by Dr S. Granick. The effects of its intravenous injection were observed in 8 rats anesthetized with pentobarbital, 4 of the animals were bilaterally nephrectomized (to exclude participation of renal V.E.M. in the response) and 4 had experimental renal hypertension (due to silk perinephritis in 1 and to the 'endocrine-kidney' technique of Selye in 3). One carotid artery was cannulated and arterial pressure measured with a mercury manometer. Each experi-

ment consisted of successive injections of ferritin solution (0.1 or 0.2 cc containing 200 to 400 μ g of ferritin) preceded and followed at intervals of 5 to 10 minutes by injections of adrenaline (0.12 μ g, intravenously). Injection of ferritin had no consistent immediate or delayed effects on arterial pressure or adrenaline response. Ferritin or its protein moiety has been identified as V.D.M. and found to inhibit the effect of local adrenaline on the terminal arterioles of the rat mesoappendix for several minutes in a dosage of about 0.005 μ g intravenously (Mazur and Shorr, 1948). From our experiments it seems that these segments of the vascular tree do not participate significantly in the pressor response to intravenous adrenaline. Further, these observations do not support the view that the presence or absence of responsiveness to adrenaline in this segment is closely related to the level of arterial pressure.

Conditions influencing explosive decompression injury E. L. COREY *Univ. of Virginia Medical School, Charlottesville, Va.* In an attempt to evaluate the multiple factors operating in conventional experiments on explosive decompression (expansion of intrapulmonary gases, anoxia, aeroembolism), over 300 tests were performed in which rats were placed in a circulating atmosphere of compressed air for varying time periods (2-30 atmospheres, 10 sec-30 min), and subsequently decompressed to ambient atmospheric pressure in c. 0.5 sec. Anoxia was thus prevented, and the effects of rapid gas expansion alone could be observed following exposures to pressure. The effects of anoxia *per se* were studied by placing animals in an atmosphere of nitrogen for suitable time intervals. In rats maintained under positive pressure for 30 min prior to decompression, 100% mortality was not attained until decompression from 11 atmospheres. In these cases pulmonary lesions were observed in only 15% of the animals, while all exhibited marked aeroembolism. Of 99 animals which succumbed in experiments of this type, 26% gave evidence of pulmonary damage, while 87% showed gross aeroembolism. Obviously time under pressure constituted a potent factor in determining survival after decompression. Thus at 30 atmospheres a time-under-pressure difference of 40 seconds was found to alter the mortality rate from 100% to zero. Aeroembolism thus appeared to be the major cause of injury in these experiments. Anoxia resulted in pulmonary hemorrhage in 50% of animals tested. Results of these tests indicated that anoxic anoxia and aeroembolism far outweigh the physical expansion of intrapulmonary gases as lethal factors in explosive decompression.

Comparative diuretic effects of neutral and alkaline sodium salts in hypoproteinemic edema SAMUEL A. CORSON and ELIZABETH O'LEARY (by invitation) *Dept. of Physiology, School of Medi-*

cine, Howard Univ., Washington, D. C. Edema was produced in trained unanesthetized dogs by means of a low protein diet and periodic massive plasmaphereses. Edema (as measured by an increase in thiocyanate space) could be produced by this method within a period of several days and maintained for several weeks. Hypertonic solutions of Na salts were administered intravenously (in the postabsorptive state) by means of a constant infusion pump at the rate of 2.5 ml/min, injecting a total dose of 10 ml/kg of body weight. The diuretic response was measured until the rate of urine flow began to approach that of the control period. A 1.4M solution of disodium salts of succinate and fumarate increased the rate of urine flow 10-fold (from a control value of 0.5 ml/min to an average value of 5 ml/min), this diuresis persisting for about 300 minutes. Subtracting the quantity of fluid injected and the fluid that would have been removed as a result of the normal urine flow, one obtains a figure of 76 ml/kg as the average net quantity of urine excreted following the administration of the alkaline salts. The injection of either 2M (isosmotic with a 1.4M disodium salt) or 2.8M NaCl (equivalent in Na content to a 1.4M disodium salt) tripled or quadrupled the rate of urine flow for a period lasting for about 300 minutes. The average net fluid output under these conditions was 24 ml/kg. Thus, intravenous administration of either neutral or alkaline sodium salts leads to the removal of large quantities of fluid in experimental hypoproteinemic edema, the alkaline salts invariably producing a diuresis approximately 3 times as great as that induced by isosmotic or equivalent solutions of NaCl.

Development of Turbulence in Flowing Blood N. A. COULTER (by invitation) and JOHN R. PAPPENHEIMER *Dept. of Physiology, Harvard Medical School, Boston, Mass.* The relations between pressure, flow and electrical conductivity of bovine blood were determined over a wide range of flows, corpuscular volumes, and temperatures in glass tubes 2.52 mm and 6.80 mm in diameter. The viscosity (calculated from Poiseuille's Law) decreases with increasing flow—a phenomenon known previously to occur in capillary tubes. Presumably change of viscosity with flow is associated with orientation of red cells in the flow stream. This orientation is beautifully demonstrated by changes of electrical conductivity along the axis of the flow stream. At zero flow the (non-conducting) cells are randomly oriented and the electrical resistance is high; as flow progresses, the cells orient to present least hydrodynamic resistance and both the (apparent) viscosity and the electrical resistance diminish in regular fashion toward constant values. Turbulence begins at an apparent Reynolds number of about 1000 as with homogeneous fluids. However, the electrical resistance remains un-

changed even at Reynolds numbers up to 2500. We, therefore, infer that turbulence occurs only in the plasma layer, while viscous flow continues in the central core of oriented cells. It appears possible to consider the apparent viscosity of blood as the resultant of two real viscosities: a) the viscosity of plasma alone in the peripheral sleeve, b) the viscosity of cells plus plasma in the central core. Evidence suggests that the rate of shear in the peripheral sleeve is so high compared with that in the central core that most of the energy required to maintain flow is dissipated in the plasma layer.

Pulmonary blood flow and alveolar ventilation-perfusion relationship following resection of one lung in man. A. COURNAND, R. L. RILEY and A. HIMMELSTEIN (by invitation). *Dept. of Medicine and Surgery, Columbia Univ. College of Physicians and Surgeons, New York City.* Pulmonary blood flow and pulmonary arterial pressure were measured at rest in 9 subjects, 14 to 72 years of age, from 1 month to 11 years after resection of one lung. In 6 the same measurements were repeated during moderate exertion. Although the pulmonary arterial pressure at rest was but slightly altered, it rose invariably during exercise. This finding is in contrast with observations in normal individuals during much more severe exercise (*Am J Physiol* 152: 372, 1948). The pulmonary artery pressure rise was small in cases where the remaining lung appeared normal on the basis of physiological measurements, while the rate of blood flow exceeded the blood flow through each lung of normal individuals during severe exercise. The maximum load which can be taken up by a normal vascular bed was therefore tested. The pulmonary artery pressure rise was larger in individuals where moderate emphysema developed in the remaining lung, although the increase in blood flow was smaller. The relationship between alveolar ventilation and perfusion was studied in these same individuals according to the method presented in these proceedings by two of the authors. They were normal in 6, in the remaining 3 there was evidence of perfusion of poorly ventilated alveoli and/or of ventilation of poorly perfused areas.

Effect of a psychiatric interview on the blood pressure response to cold stimuli. ROBERT W. CRANSTON (by invitation), JAMES H. CHALMERS (by invitation), HENRY LONGSTREET TAYLOR, AUSTIN HENSCHEL and ANCEL KEYS. *Laby of Physiological Hygiene, Univ. of Minn., Minneapolis, Minn.* The blood pressure responses to a 'cold pressor' test of 9 well-adjusted healthy young men 18 to 24 years old were studied on six occasions during a control period of 7 months. The cold test was standardized as to time of events, relation to meals and activity and psychological atmosphere. Blood pressures were measured by means of a sphygmomanometer and stethoscope

with the subject supine during a suitable control period and during the immersion of the hand in ice water for one minute. Each subject was interviewed by the psychiatrist for 5 to 8 hours during the 7-month control period to learn his psychodynamics. When preliminary observations were completed, an interview was arranged in which emotionally charged topics were intentionally introduced by the psychiatrist. There was a mild emotional response of hostility and resentment in the majority of cases but no marked emotional reactions. The interview produced variable but small changes in the resting blood pressure. At the end of the interview, the blood pressure response to cold was determined. The grand average of the mean individual increases in the systolic blood pressure during the control period was 16.03 mm Hg. The mean response to cold after the psychiatric interview was 24.2. This difference was significant at the 1% level.

Sodium and potassium depletion in rats by means of cation exchange resins mixed with food. J. M. CRISMON. *Dept. of Physiology, Stanford Univ. School of Medicine, Stanford, Calif.* Maintenance of negative sodium balance with the aid of ingested cation exchange resins as suggested by Dock (*Trans. Assn. Am. Physicians* 59: 282, 1946) has received little study and few clinical trials have been reported. Intakes of sodium and potassium and fecal loss of these cations from 10 rats were measured every other day for 23 days. After a 9-day control period, 10% by weight of acid-treated -200 mesh Dowex 50, a sulfonated polystyrene resin was added to the diet. After addition of resin 100 gm of diet contained, by analysis, 30.3 mEq of sodium and 16.0 mEq of potassium. On the 18th day sodium in the diet was reduced to 18.9 mEq/100 gm and potassium to 13.7 mEq/100 gm. During the control period 96% of ingested sodium and 94% of ingested potassium were absorbed from the gut. During high sodium intake, plus resin, absorbed sodium decreased to 70% and potassium to 82% of the amount ingested. On reduced sodium intake, absorbed sodium decreased to 34%, potassium absorption was still 82%. The low sodium diet containing resin was fed for an additional 10 days, and the animals were killed. Plasma sodium varied from 142 to 167 mEq/l with a mean value of 152. Potassium concentrations were slightly low with a mean of 3.2 mEq/l, the range was 2.3 to 3.9. Muscle sodium, potassium and chloride were low with the following mean values in mEq/100 gm of fat-free dry muscle: Na = 6.68 (4.46 - 9.26), K = 36.8 (32.1 - 40.6), Cl = 5.37 (4.65 - 5.98).

Action potential of heart muscle. HOWARD J. CURTIS. *Dept. of Physiology, Vanderbilt Univ. Medical School, Nashville.* By microdissection methods it has been found possible to isolate small,

homogeneous bundles of muscle fibers from the turtle heart in which the fibers are all parallel and there are very few anastomoses between fibers. These bundles are transferred to mineral oil and stimulation and electrical recording is effected by means of microelectrodes. At about 10°C spontaneous activity is almost absent. When both recording electrodes are on active muscle, the conducted action potential is monophasic, as contrasted with the diphasic action potential of skeletal muscle under the same circumstances. The monophasic wave is followed by a T-wave which may be either positive, negative or diphasic. When one end of the bundle is crushed or treated with isotonic KCl a resting potential of 10 millivolts or more is recorded. The action potential now falls from the level of the resting potential to zero and remains there for as long as 2 seconds and then relatively rapidly returns to the level of the resting potential. Preliminary estimates indicate that the period of depolarization corresponds closely with the period of contraction and with the S-T interval. Thus the initial part of the action potential represents conduction in the individual muscle fiber presumably by the same mechanism as for skeletal muscle, but unlike skeletal muscle repolarization is delayed for a relatively long time. The T-wave is not a conducted response and represents true cellular re-polarization.

Attempted blockade of the adrenotrophic mechanism of the pituitary in starvation. SAVINO A. D'ANGELO *Dept of Biology, Washington Square College of Arts and Science, New York Univ, New York City*. It has been demonstrated (D'Angelo, Gordon, and Charipper *Endocrinology* 42: 399, 1948) that starvation in the guinea pig fires the adrenotrophic mechanism of the anterior hypophysis and causes marked enlargement of the adrenals. Although reciprocal regulatory control between anterior pituitary and adrenal cortex is shown by adrenal depression with cortical hormone overdosage in the fed animal, it appears that in the guinea pig the cortical hypertrophy of starvation cannot be blocked. Female guinea pigs (300-350 gm) were subjected to acute starvation during which cortical hormone was maintained at presumably high levels in the body fluids by administering subcutaneously aqueous cortical extract (Upjohn) in 3 cc doses every 3 hours, 4 times daily, for 9-11 days, and by giving cortical extract in the drinking water as well. Each animal received approximately 150 cc of the cortical extract over the starvation period. Adrenal enlargement occurred with mitosis frequently encountered in the outer fasciculate region of the cortex. Cytological study of the pituitary indicated high rather than suppressed secretory activity. Two marked peripheral effects were observed in the cortical-treated animals, 1) oliguria and 2) marked leuco-

cytosis characterized by a pronounced increase in the numbers of neutrophils showing advanced stages of nuclear lobulation. Further studies on the peripheral blood and on the marrow following high cortical dosage are being made.

Effects of steroids on the endocrine system of the starved guinea pig. SAVINO A. D'ANGELO, ALBERT S. GORDON and HARRY A. CHARIPPER *Dept of Biology, Washington Square College of Arts and Science, New York Univ, New York City*. In female guinea pigs acutely starved to 40% body weight loss by complete food deprivation (water allowed), the thyroid lost at a lesser rate (18%), the ovary at about the same rate (44%), and the cervical lymph nodes at a greater rate (68%) than did the body. In contrast, the adrenal underwent absolute hypertrophy (60%) with commensurate increase in solid contents. The results obtained following the subcutaneous administration (6-11 days) of various steroid preparations in high daily doses (Progynon B, 600 RU, progesterone, 15 mg, desoxycorticosterone acetate, 18 mg, lipoadrenal extract, 1 cc, aqueous cortical extract, 10 cc) indicate that estrogen, desoxycorticosterone and lipo-adrenal, but not progesterone, augmented the adrenal hypertrophy of starvation. The solid content of these enlarged adrenals was correspondingly increased and microscopic examination further indicated a true increase in cortical mass. In the fed animal only the aqueous cortical extract affected adrenal weight (by depression) but desoxycorticosterone and aqueous cortical extract both caused involution of the zona glomerulosa in the adrenals of fed animals. A marked difference on the adrenals was found between the steroid vehicles used. Peanut oil given in 1-cc daily injections for 9-11 days caused marked adrenal enlargement in fed or starved animals, whereas, sesame oil in equivalent or greater amounts was without effect. The various steroids employed did not appreciably influence thyroid and ovarian weights in either the starved or fed animal, and the regression of the lymph nodes in starvation bore no apparent relationship to the adrenal hypertrophy. The involvement of the anterior pituitary in the end organ response to starvation is considered.

Rise in serum precipitable or protein-bound iodine following massive doses of inorganic iodide. T. S. DĄWOWSKI and J. H. GREENMAN (by invitation) *Dept of Research Medicine, Univ of Pittsburgh School of Medicine, Pittsburgh, Penn*. Riggs, Laviates and Man (*J Biol Chem* 143: 363, 1942) demonstrated that both inorganic and protein-bound iodine is present in plasma. The work of Taurog and Chaikoff (*J Biol Chem* 165: 217, 1946) with rats indicated that, within limits, increases in the intake of inorganic iodide were accompanied by a rise in the organic iodine of the thyroid gland and plasma. The maximum level of

circulating total iodine recorded was 33.6 gamma %, and the changes in the circulating protein-bound iodine, though definite, were quite small.

This report deals with the relationship between the intake of inorganic iodide and the level of circulating serum precipitable or protein-bound iodine found in 4 patients to whom massive doses of potassium iodide (up to 3 gm daily), or of a saturated solution of potassium iodide (up to 7 cc daily), had been given during 4 to 18 weeks. This resulted in total serum iodine levels of 2,100 to 18,100 gamma %. Serum precipitable iodine measured by the method of Barker (*J Biol Chem* 173:715, 1948) slightly modified, rose progressively as to high as 31.7 gamma %. Removal of any traces of inorganic iodide which would yield false high values was assured by obtaining checks on two separate sets of duplicate or triplicate aliquots of precipitated serum, one set of which was washed with 14 and the other with 18 successive changes, 25 cc each, of double distilled water. Iodism did not develop nor were these high levels of protein-bound iodine associated with hypermetabolism.

Age and osmotic work in urea excretion D F DAVIES (introduced by H A SCHROEDER) *Section on Cardiovascular Disease and Gerontology, National Inst of Health, Bethesda, Md and Baltimore City Hospitals, Baltimore, Md* Previously reported results on degenerative changes in renal function with age have indicated a primary vascular defect. The possibility was considered that this reduction in renal function was caused by lowered metabolic rate and decreased work requirement of the kidney in old age. If this were true, the kidney could be said to undergo an atrophy of disuse having no deleterious effect on other body functions. To examine this hypothesis data on basal urea production, tubular reabsorption of urea, urea clearances and blood and urine urea concentrations were examined for their relationship to their contribution to osmotic work in adult men between the ages of 20 and 90. Urea clearance decreased with age at a rate comparable to that of glomerular filtration rate and tubular excretory capacity after the 5th decade. Tubular reabsorption of urea followed a progressive decline during the seven decades studied. Most of this fall is explained by decreased filtration rate. Urea production (excretion) showed no significant correlation with age. Blood urea concentration showed a moderate increase with age. Calculation of renal osmotic work of urea excretion showed that there is an increase in the amount of osmotic work per unit of functioning kidney tissue with increasing age. Unless a significant and consistent decrease in salt intake occurs during the aging process, involutional changes due to decreased work requirement cannot be the cause of the decrease in effective renal blood flow and excretory functions associated with aging.

Theophylline ethylene diamine and renal function in control subjects and decompensated cardiac patients JAMES O DAVIS (by invitation) and NATHAN W SHOCK *Section on Cardiovascular Diseases and Gerontology, National Heart Inst, National Inst of Health, Bethesda, Md, and the Baltimore City Hospitals, Baltimore, Md* Inulin, diodrast and sodium clearances were determined during 3 control periods and during 5 periods after the intravenous administration of 0.48 gm of theophylline ethylene diamine (TED). In control subjects, an elevation in GFR and Cl_{Na} was sustained for 50-60 minutes. The rise in effective RPF was usually transitory. Statistically, the ratio E_{Na}/Cl_{Na} was more variable and of significantly greater magnitude after than before the injection of TED. This finding indicates that increased sodium excretion cannot be regarded as solely the result of augmented GFR and suggests that TED acts upon the renal tubules to decrease sodium reabsorption.

Patients in congestive heart failure were divided into two groups according to the level of Cl_{Na} before TED administration. In the low Cl_{Na} group, GFR was usually within normal limits but effective RPF was consistently low. In the elevated Cl_{Na} group both GFR and effective RPF were reduced. This evidence indicates that a low GFR is not the primary mechanism for salt retention in patients with cardiac failure. The response in GFR and effective RPF in heart failure patients ranged from a negligible elevation to an increase greater than 100%. Unlike the response in controls, the elevation in GFR lasted for 10-20 minutes only, the increase in Cl_{Na} was usually sustained for 50-60 minutes. The lack of correlation between the duration of the elevation in GFR and Cl_{Na} indicates that the sustained increase in Cl_{Na} is the result of decreased tubular reabsorption of sodium.

Role of the adrenal cortex in the abnormal insulin and adrenaline response of hypophysectomized dogs R C DE BODO, S P KIANG (by invitation) and I H SLATER (by invitation) *Dept of Pharmacology, New York Univ College of Medicine, New York City* It was previously suggested (*Federation Proc* 7:116, 1948) that the gradual development of insulin hypersensitivity and resistance to adrenaline hyperglycemia in the hypophysectomized dog might be related to the secondary atrophy of the adrenal cortex and thyroid. Hypophysectomized dogs manifesting maximal insulin hypersensitivity (more than 60 fold) were given potent adrenal cortical extract (ACE). The total dosage, route and time of administration were varied. Administration of ACE both on the previous day and again 4-5 hours before insulin gave the optimal effect. While 1500 DU had little effect, 3500-4000 DU (for 15- to 20-kg dog)—an amount many times the maintenance dose for

adrenalectomized dogs—produced the following effects 1) it elevated somewhat the post-absorptive blood sugar, 2) after insulin (0.025 U/kg i.v.) it prevented the fall of blood sugar to the usual low level—hypoglycemic signs did not develop—and markedly accelerated the recovery to post-absorptive levels. It did not, however, alter the rate of the blood sugar drop. Though ACE in massive doses exerted some 'anti-insulin' action, reversion to a normal response was never achieved. In each case the insulin-induced hypoglycemic response in the ACE-treated animal closely resembled the response obtained in the animal 2-3 days after hypophysectomy.

Similar studies with ACE were made on the adrenaline response of hypophysectomized animals showing resistance to the hyperglycemic action of adrenaline. In every instance, the effect was small and in no case was a return to a normal response noted.

Protein utilization in hypophysectomized dogs
R. C. DE BODO, S. P. KIANG (by invitation) and I. H. SLATER (by invitation) *Dept. of Pharmacology, New York Univ. College of Medicine, New York City*. Houssay showed that hypophysectomized dogs when compared with normals have a markedly decreased nitrogen excretion on fasting, but a normal nitrogen output on meat diet. Soskin found that meat-fed hypophysectomized dogs were able to sustain a normal blood sugar and that after fasting recovery from hypoglycemia occurred with meat feeding. Considering the importance of these observations which might suggest a distinction between 'endogenous' and 'exogenous' protein metabolism in hypophysectomized dogs, it was felt that re-examination of the problem was warranted. We have found that hypophysectomized dogs were able to maintain and even increase their post-absorptive blood sugar level and increase their body weight when fed a trypsin hydrolysate of casein (with vitamin supplement) for a period of three weeks. In a second series of experiments when hypophysectomized animals were fasted, prompt recovery of the blood sugar from hypoglycemic levels was noted within one hour after the feeding of the hydrolysate.

During fasting the hypophysectomized dogs showed a decrease in nitrogen excretion to about $\frac{1}{4}$ of that noted in normal animals after comparable or even longer periods of starvation. These hypophysectomized animals showed also a diminished output of potassium and phosphate with unchanged serum levels, a further indication of impaired breakdown of intracellular protein. Thus, we have been able 1) to confirm and extend the previous observation, that while the metabolism of body protein is defective in the hypophysectomized animal, the utilization of fed protein is adequate and

2) to demonstrate that the conversion of amino-acids to carbohydrate is very rapid.

A constant delivery pipette particularly designed for analysis of small volumes
R. C. DEERING (introduced by H. C. BAZETT) *Dept. of Physiology, Univ. of Pennsylvania Medical School, Philadelphia, Penna.* Direct determinations of cardiac output require special methods for analyzing small blood samples for which a modification of the Guest pipette possesses advantages. The pipette consists of a calibrated glass tube joined at each end by two-way stopcocks. The capillaries of the upper stopcock connect the calibrated tube to a) a cup similar to that of the Van Slyke apparatus or b) a smaller overflow cup. The capillaries of the lower stopcock connect it to a) a sample inlet tube or b) a stem having a rubber tip. The pipette serves to introduce a sample into a Van Slyke apparatus after which standard procedure is followed. The stem, supported by a rubber stopper, is placed in the analyzer cup. For analyses of 0.2-ml. samples, gas-free lactic acid is run into the upper cup, the cocks are reversed and the calibrated section washed and dried. The pipette is filled directly from collecting syringes, the blood sample, preceded by a mercury 'cap,' being forced up the pipette section to the overflow cup. The cocks are reversed cutting off a contained volume. The blood, followed by a mercury drop and the lactic acid, is run into the chamber, thus introducing the whole sample. Present experience indicates a greater accuracy of sample-introduction, so that consistency with 0.2-ml. samples is equivalent to that commonly obtained with 1 ml. With 0.5 ml., conditions are improved and the procedure simplified. Accuracy attained will be illustrated with data obtained on samples from the right heart.

Influence of work on the amount of K-strophanthoside stored by muscle
E. C. DEL POZO, G. ANGUIANO (by invitation) and E. G. PARDO (by invitation) *Inst. de Salubridad y Enfermedades Tropicales Mexico, D. F., Mexico*. It is generally thought that striated muscle is able to store only very small amounts of digitalis glycosides. The heart, on the other hand, can take up much greater amounts per gram of tissue. The cause of this selective storage of digitalis bodies by the heart is not yet settled. While the values known for skeletal muscle have been obtained by perfusion experiments on inactive muscle, the values for the heart have been measured in preparations in which the heart is working. There is the possibility that the absence of muscular work may be a factor in determining the difference observed between the storage by the heart and the storage by striated muscle. In view of this, the influence of activity on the amount of K-strophanthoside taken up by skeletal muscle was analyzed. This was done by determining the *dosís certa letális* (d.c.l.) of said

glycoside for cats under dial anesthesia. In one half of the series of 80 cats the muscles innervated by both sciatic nerves were continuously stimulated at a frequency of 5/sec. The average d.c.l. for the cats whose muscles were thus stimulated was significantly higher than that for the control animals. This seems to indicate that the muscles in activity took up greater amounts of the glycoside. These results could have a bearing on the selective storage of digitalis bodies by the heart, which is in constant activity.

Differences in the effects of cold environment and of muscular work on adrenal function. A. DESMARAIS (introduced by L. P. DUGAL) *Dept. d'Acclimatation, Inst. de Biologie Humaine, Univ. Laval, Quebec, Canada*. It has been shown by Selye (*Arch. internat. de pharmacodyn. et de therap.*, 55: 432, 1937) that adrenalectomized rats adapted to muscular work (revolving cages) are able to perform more work than non-trained, non-adrenalectomized rats. Since cold temperature is being regarded as an alarming stimulus having the same effects on adrenal function as muscular work, it was of interest to observe if adrenalectomized rats adapted to cold would resist better than non-adapted, non-adrenalectomized animals. The results show that the latter group, contrary to what one could expect, is significantly more resistant to cold than the adrenalectomized, adapted group. The difference between both types of stress is striking for the above experiment, but less so if one compared adrenalectomized animals adapted and non-adapted.

Further observations on the hypotensive effects of intravenous injections of hypertonic solutions. INGRITH J. DEYRUP (by invitation) and WILLIAM W. WALCOTT *Dept. of Zoology, Barnard College, and of Physiology, College of Physicians and Surgeons, Columbia Univ., New York City*. It was reported previously (Walcott and Deyrup *Am. J. Physiol.*, 155: 1948) that, in the anesthetized dog, the intravenous injection of hypertonic solutions is followed by a fall in blood pressure which is consistently different from a marked and characteristic hypotension resulting from injection of mixtures of hypertonic solutions with homologous blood. Thus, whereas the injection of 12 to 30 ml. of 5 to 7% NaCl results in a diphasic fall in blood pressure, there is a profound and rapid single phase fall following injection of an equivalent volume of an equally concentrated mixture of blood and hypertonic NaCl. A related phenomenon has been observed in rabbits (nembutal, ether) but not in cats (nembutal). The striking difference between the cardiovascular response to injection of mixture of blood with hypertonic solutions, as compared with the effects of hypertonic solutions alone, suggests that the hypotension following the injection of such solutions may result, at least in part, from

the interaction of some component of the blood with the hypertonic solution. In line with this hypothesis, we have obtained evidence that, under specifically defined conditions, a depressor substance may be demonstrated in approximately isotonic solutions derived from mixtures of hypertonic solutions with whole blood or erythrocytes suspended in 0.9% NaCl. An attempt has been made to characterize the depressor substance thus obtained, and to compare it with other depressor substances (various ions, histamine, compounds related to choline and adenosine).

Carbohydrate utilization and lactate formation in the chicken retina. H. F. DIERMEIER and V. F. LINDEMAN (introduced by Robert Gaunt) *Dept. of Zoology, Syracuse Univ., Syracuse, N. Y.* The retina has one of the highest rates of glycolysis of any tissue of the body. In order to find the source of the lactate produced by this tissue the following determinations were conducted on chicken retina kept at 37.5°C: glycogen content before and after incubation for one hour; glucose utilization with varying concentrations of glucose in the incubation media; lactate production. Chemical assays were carried out by photometric analysis. All experiments were conducted under aerobic conditions. Ten experiments on matched retina are reported. Weights are given as wet weight. The average glycogen content (Morris, *Science* 107: 1948) immediately after removal from the eye was 0.0032 mg glycogen (glucose equivalents) per mg retina. After one hour of incubation in Krebs-Ringer solution with 0.1% glucose as substrate the value was decreased to 0.00227 mg/mg of retina. The incubated retina consumed an average of 0.0205 mg of glucose/mg of tissue from the substrate and produced 0.00919 mg of lactate/mg of tissue.

In an attempt to account for the utilized carbohydrate not in the form of lactate, oxygen consumption measurements were made using the direct method of Warburg. The average oxygen consumption in the Krebs-Ringer solution with 0.1% glucose added was 0.507 cmm/mg of tissue (wet wt.) per hour. Oxygen consumption with no glucose added as substrate was 0.279 cmm/mg tissue (wet wt.) per hour. Oxygen consumption does not account for the remainder of the carbohydrate utilized and further experiments are in progress.

Identification of chloramphenicol (chloromycetin) degradation products by paper chromatography. WESLEY A. DILL (by invitation) and ANTHONY J. GLAZKO *The Research Lab. of Parke, Davis and Company, Detroit, Mich.* The paper strip chromatographic methods of Consden, Gordon and Martin (*Biochem. J.* 38: 224, 1944) were applied to the separation of chloramphenicol (Parke, Davis) and its degradation products in urine. Using *N*-butanol with 2.5% phenol and 2% pyridine added it was possible to separate chloramphenicol (I), a

hydrolysis product (II) and a conjugate (III) on a single strip of paper. After developing the chromatogram, colored derivatives were formed on the strip by reduction with titanous chloride, oxidation of excess reagent with bromine, diazotization with butyl nitrite and coupling with the Bratton-Marshall reagent. Small amounts of I and II were found in the urine of man by chromatography after administration of chloramphenicol, with large amounts of III being present. Dog urine showed larger amounts of II than man. III was identified in the urine of man, dog, and rat, with the compound having approximately the same R_f value in all cases. The conjugate (III) was isolated by use of the counter-current extraction technic, and provisionally identified as the monoglucuronide. Following hydrolysis of III with β -glucuronidase, chloramphenicol (I) and free glucuronic acid were identified separately by paper chromatography. Two-dimensional paper chromatograms of urine were also prepared using *n*-butanol with 3% acetic acid and again with 3% ammonium hydroxide added. I, II and III were identified by comparison with known compounds, and, in addition, at least one other derivative of chloramphenicol was found to be present.

Potential gradient vs current density in electrical control of axial polarity in regenerating *Dugesia tigrina* JEAN DIMMITT (introduced by GORDON MARSH) *Zoological Laby, State Univ of Iowa, Iowa City, Ia*. Sections of *Dugesia tigrina* were exposed to direct current for 120 hours (original posterior end facing the cathode), in solutions of specific resistance from 478.4 to 52,157 ohm-cm, at 21°C. One hundred % mortality was found below 1000 and above 15,000 ohm-cm. For media of 1031 (previously reported), 2400, 7237, 10,605 and 12,600 ohm-cm, the potential gradients in mv/mm across the regenerating pieces were constant for the following morphological effects, although the current densities varied 12-fold (values in parentheses are for 1031 ohm-cm, others are averages for all data): 178 (177) for regressive bipolars, in which head structures appear on both ends but disappear from the original posterior end within 3 days after removal from the current, 185 (193) for permanent bipolars, 198 (200) for progressive bipolars in which the head on the original anterior end is reorganized into a tail after removal from the current, and 217 (212) for complete reversal of axial polarity. Since constant current density is not the determinant of a given morphogenetic effect it may be concluded that control of polarity and differentiation is not determined by a stable relationship between the regenerating piece and its environment, nor by a critical rate of internal ion transport, i.e., by features of capacity. Constancy of potential gradient may be interpreted as the attainment of a critical discharge voltage (valence

change) for some essential ion, orientation of molecules having a characteristic dipole moment, establishment of a liminal counter-E M F or the overcoming of an inherent potential difference.

Antifibrillatory properties of N-methyl-N-(3,4-dimethoxybenzyl) β -(4-methoxyphenyl)-ethylamine hydrochloride JOSEPH R. DiPALMA, JOSEPH J. LAMBERT (by invitation), RICHARD A. REISS (by invitation) and JOHN E. SCHULTS (by invitation) *Dept of Physiology and Medicine, Long Island College of Medicine, Brooklyn, N. Y.* By use of a thyatron stimulator set at 600 impulses/min and electrodes attached to the right auricle of intact open-chest cats the fibrillation threshold for the new compound was determined. Quinidine and α -Fagarine were also assayed for comparative purposes. The new compound proved to be 2.3 times more active than quinidine and 1.3 times more active than α -Fagarine. The average acute lethal i.v. toxicity for cats was less for the new compound as compared to quinidine and α -Fagarine. On i.v. injection the new compound caused a transitory slowing of the pulse and a fall in blood pressure. In this respect and in the EKG changes produced with higher doses it resembled quinidine. It was also demonstrated that the refractory period of frog skeletal muscle was markedly prolonged by the new compound. In humans with normal hearts the new drug in equivalent doses 1 m. caused a greater lengthening of the Q-T interval than did quinidine. Also in human chronic fibrillation the f-f interval was increased more by the new compound than by quinidine. The interesting features of the new compound may be listed as follows, it does not have a quinoline structure yet it is remarkably potent, its activity apparently stems in part from the proper substitution of methoxy groups, its structure is simple enough to offer important leads as to the basic chemical moiety necessary for antifibrillatory action and finally it may prove to be superior to quinidine and α -Fagarine for the therapy of fibrillatory states in human beings.

Separate inhibition of resting and active oxygen consumption of functioning nerves R. W. DORF (by invitation) and R. W. GERARD *Dept of Physiology, Univ of Chicago, Chicago, Ill.* To study resting and active respiration, a modified capillary microrespirometer was developed to permit measurement of action potential and oxygen uptake of 10 separate nerves. The Q_{O_2} of nerves from one frog agree within 10%. The action of Na azide and methyl fluoroacetate (MFA) has been studied, yohimbin explored. Drugs were applied by soaking for an hour before mounting a nerve, stimulation was kept maximal at 120/sec, temperature range was 20-25°C. Azide, 0.1 mM, and probably yohimbin, 0.01 mM, can depress the increased Q_{O_2} of activity while leaving the action potential height

normal Resting Q_{O_2} may be somewhat depressed with azide, in which case conduction has gradually failed, but when normal, and with no increase on stimulation, conduction can continue unimpaired for at least 4 hours (confirming Bronk *et al*) MFA, by contrast, is able to depress resting Q_{O_2} without diminishing the increase on stimulation At 1 mM, resting Q_{O_2} is decreased 25% while the active increase is normal At 5 mM, resting Q_{O_2} is halved and the active increase may be intact, depressed or even abolished In any case, action potential may remain at normal height, one nerve, with the active increase present, being tetanized for 7 hours In interpreting these results, the presence of respiring non-conducting elements in a nerve trunk must be considered

'Saturation tension' and alveolar-arterial pO_2 gradient as expressions of 'venous admixture' in the lungs J C DOUGLAS (by invitation), R L RILEY and A CURNAND *Dept of Physiology, Univ of Western Ontario Medical School, London, Ontario, and of Medicine, Columbia Univ College of Physicians and Surgeons, New York City* The 'saturation tension' as measured with the Millikan oximeter during high oxygen breathing and the alveolar-arterial pO_2 gradient as measured by analysis of arterial blood and expired air during ambient air breathing have been studied in normal subjects and in patients with chronic pulmonary disease Both methods provide information from which 'venous admixture' in the lungs can be calculated The 'saturation tension' may be defined as the partial pressure of oxygen in the inspired air required to produce complete saturation of the mixed arterial blood The required increase in pO_2 above atmospheric, in any given patient, is due chiefly to the lowering of the mixed arterial pO_2 by addition of blood which has been inadequately exposed to oxygen before entering the left heart This blood has been called 'venous admixture' The mixed arterial blood may be completely saturated in spite of a considerable proportion of 'venous admixture' Increasing the inspired pO_2 raises the oxygen tension in poorly ventilated alveoli until at a certain inspired pO_2 all ventilated alveoli saturate the blood in contact with them In addition blood perfusing non-ventilated portions of lung (or separated from alveolar gas by an impermeable barrier) is saturated by the excess dissolved oxygen in the blood from well ventilated areas 'Venous admixture' as calculated from the alveolar-arterial pO_2 gradient during ambient air breathing involves the same factors but probably weights more heavily the effect of poorly ventilated alveoli

Spectrophotometric determinations of Brilliant Vital Red and T-1824 in serum PHILIP DOW and RAYMOND W PICKERING (by invitation) *Dept of Physiology, Univ of Georgia School of Medicine, Augusta, Ga* Hamilton and collaborators (1932,

1940) have demonstrated that Brilliant Vital Red can be accurately and conveniently determined in the supernatant of an ethanol precipitation of serum by colorimetric comparison with similarly treated standards, T-1824 has universally been found to go down with the precipitate Anomalies encountered in adapting the method for photoelectric colorimetry led to an investigation by Beckman spectrophotometry As progressively more dilute ethanol (always 10 volumes) was used to clarify the serum (dog), a larger fraction of both dyes remained in solution, roughly paralleling the albumin solubility The two dyes differed quantitatively, BVR being only 60% removed by absolute, not at all by less than 88% ethanol, T-1824, 93% removed by absolute, negligibly only at 80% ethanol Below 82% ethanol, inconstant cloudiness vitiated determinations

As previously emphasized, the ethanol precipitation provides a much clearer and more constant blank in the face of considerable variations in color and cloudiness of the original serum Hemoglobin as such is removed completely Some ethanol supernatants show no color whatever, even from severe hemolysis In others an as yet unidentified derivative of hemoglobin (probably a ferriporphyrin) is extracted in small amounts It absorbs comparatively little light at 508 or 625 $m\mu$ (the dye peaks) and has a high sharp peak at 404 $m\mu$ where the dyes absorb only slightly Correction can thus be easily made by reading at two wave-lengths and applying the customary formula Other methods of minimizing this contamination are being studied

Cardiac changes in monkeys following explosive decompression to extreme altitudes ROY DOWLING (by invitation) and SAMUEL GELFAN *Laby of Physiology, Yale Univ School of Medicine, New Haven, Conn* Cardiac changes following explosive decompression to simulated altitudes of as high as 75,000 feet have been studied in anesthetized monkeys by means of unipolar lead electrocardiography, recording simultaneously from three extremity leads Recompression of the animals at free fall rate began immediately after the sudden decompression The first observable change in the *ecg* complex is the displacement of the S-T segment, which occurs between 5 to 30 seconds after the sudden decompression This change is quickly followed by an increase in the P-R interval and simultaneously an absolute shortening of the Q-T interval, even during the marked bradycardia that develops The Q-T interval shortening indicates an acceleration of repolarization and the elevation of S-T segment in the VL and VF leads and depression in VR leads indicates that it is the left anterior ventricle that repolarizes faster than the rest of the heart The increase in irritability of this part of the heart is also indi-

cated by the extra systoles that arise from the left anterior ventricle. Heart block ranging from first degree to complete block were also observed. The e c g complex returns to normal after recompression to sea level.

These cardiac changes are due to the anoxia rather than the pressure changes. The same alterations have been observed in 100% N₂ anoxia without pressure changes. Similarly, sudden decompression from sea level to 40,000 feet in O₂, at which altitude the anoxia is insignificant, does not alter the e c g complex. Roentgenograms show a dilation of the heart during the anoxia following decompression and also following N₂ anoxia.

Studies in pancreatic function II Statistical studies of secretin responses in individuals without pancreatic disease DAVID A. DREILING (by invitation) and FRANKLIN HOLLANDER *Gastroenterology Research Lab., The Mount Sinai Hospital, New York City*. Amylase, bicarbonate and volume responses to secretin were studied in 172 patients without pancreatic disease, to set up criteria of normalcy. One series of data, with Secretin-Wyeth alone, and another series with several different preparations were compared with data published by other investigators. Duodenal contents were collected by continuous suction through a double lumen gastroduodenal tube for 80 minutes following intravenous administration of 1 l u of secretin/kg body weight. This collection time was used, rather than the shorter intervals advocated by others, because it represents the entire period of secretory activity in response to hormone stimulation. Best agreement among the various series was shown by the means for maximum bicarbonate concentration in mEq/l, also, the corresponding coefficients of variation were least. Poorest agreement and greatest scatter were shown by the amylase data, in activity u/cc or total nu/80 min/kg. Volume data in cc/80 min or cc/80 min/kg were intermediate. The following norms were established for future performance of this test with Secretin-Wyeth: maximum bicarbonate concentration, 92-124 mEq/l, total volume, 2.0-4.4 cc/80 min/kg, total amylase secretion, 8.0-20.4 u/80 min/kg. Bicarbonate and volume responses are more valuable than amylase determination, due partly to unknown pancreozymin content of different secretin preparations, and partly to alterations of vagal tone during the test. Nevertheless, amylase activity manifests sufficient statistical homogeneity to merit its inclusion in the study of pancreatic function.

Site of action of mercurial diuretics JOHN J. DIGGAN (by invitation) and ROBERT F. PRITS *Dept of Physiology, Syracuse Univ College of Medicine, Syracuse, N Y*. Two lines of evidence indicate that organic mercurial diuretics block

distal tubular absorption of sodium. 1) When saline is infused into normal dogs at such a rate that 800 to 1200 μ Eq of sodium are excreted per min, the intravenous administration of 60 mg Hg as mercurhydrin, increases sodium excretion to 2000 μ Eq/min. Doubling the dose to 120 mg Hg increases sodium excretion to 2400 to 2500 μ Eq/min. Quadrupling the dose to 240 mg does not increase it further. The administration of BAL returns excretion to the control range. It is apparent that mercurhydrin can block the absorption of a maximum of 1500 μ Eq of sodium per min, a quantity roughly equal to 15% of that absorbed during the control periods and after BAL. This finding is consonant with the view that 80 to 85% of the sodium which is absorbed is absorbed in the proximal tubule (not mercurial-sensitive), and 15 to 20% in the distal tubule (mercurial-sensitive). 2) The administration of 45 mg Hg as salyrgan to a normal dog increases sodium excretion some 800 μ Eq/min. The infusion of 500 mU of pitressin per hour increases excretion to a variable degree, i.e. from 200 to 500 μ Eq/min. The addition of salyrgan during pitressin naturesis increases sodium excretion only to the level attained with salyrgan alone. Apparently, pitressin and salyrgan block sodium absorption at the same site, presumably in the distal segment.

Effect of l-arterenol on the peripheral circulation in man D. DUNCANSON (by invitation), T. STEWART (by invitation) and O. G. EDHOLM *Univ of Western Ontario, Ontario, Canada*. Forearm and hand blood flow were measured together with blood pressure and a continuous recording of heart rate with a cardi tachometer. L-Arterenol HCl (nor-adrenaline) was injected intravenously with a constant infusion apparatus, at a rate of 2, 5 and 10 μ g/min for 5 minutes in each instance. The forearm blood flow showed no change with 2 μ g/min but with 5 or 10 μ g/min the blood flow showed a slight reduction in flow at a time when both systolic and diastolic blood pressure were raised. Hand blood flow showed a marked and consistent decrease with 5 or 10 μ g/min. In most cases 2 μ g/min had no definite effect. The heart rate slowed consistently with infusions at the rate of 5 or 10 μ g/min. In a few instances 2 μ g L-Arterenol also produced a definite slowing.

Relation of the adrenal and spleen in regulation of the leucocyte picture of the rat ABRAHAM DURY and HABEEB BACCHUS (by invitation) *Dept of Physiology, George Washington Univ School of Medicine, Washington, D C*. The relation of the adrenal and the spleen as a factor in the regulation of the total white cell count, and the absolute number of circulating lymphocytes, neutrophils, and eosinophiles was investigated by determining whether statistical differences existed in groups of rats before and after adrenalectomy, splenec-

tomy, adrenalectomy-splenectomy, and sham operations as regards these leucocytes. A similar procedure was followed in these categories of operated groups of rats to determine the effect of adrenaline on the components of the leucocyte picture. It was found that the total white cell count was significantly increased only following splenectomy or following adrenaline treatment of the adrenalectomized rat. None of the operative procedures altered the absolute number of lymphocytes, but these cells could be significantly depressed following adrenaline treatment only when both the adrenal and the spleen were in situ. The neutrophils were significantly increased following either adrenalectomy or splenectomy but were unaffected by adrenalectomy-splenectomy. Following adrenaline treatment, the absolute number of neutrophils was not significantly increased only in the splenectomized group of rats. The number of eosinophiles was found to exhibit great variability from group to group of normal rats, but the evidence was clear that both the adrenal and the spleen were required if a significant depression in the circulating eosinophiles were to follow adrenal treatment.

Arterial and venous potassium levels in man D P EARLE, S J FARBER (by invitation) and J D ALEXANDER (by invitation) *Dept of Medicine, New York Univ College of Medicine, New York City*. When proper precautions were observed the normal resting venous plasma potassium level in man was found to be approximately 0.5 mEq/l less than generally reported. Blood was drawn into oiled syringes, transferred to tubes containing dried heparin and centrifuged immediately. Results were not affected by the use of a tourniquet to assist in obtaining blood, but muscular activity in the extremity raised the plasma K level. Hemolysis and allowing the cells to remain in contact with the plasma more than 10 minutes caused an increase in the plasma K level. At rest, arterial and venous plasma usually contain the same amount of K although at times there was more in the venous sample. Muscular activity raised the plasma K acutely and venous plasma from the extremity contained more K than the arterial. During intravenous infusions of glucose, venous plasma also contained more K than arterial, a difference which persisted following insulin in spite of a fall in both venous and arterial plasma K levels.

Measurement of cold and warmth thresholds of subjects exposed to environments from 18°C to 38°C FRANKLIN G EBAUGH, JR and RUDOLF THAUER (introduced by EUGENE F Du Bois) *New York Hospital and the Depts of Medicine and Physiology, Cornell Univ Medical College, New York, N Y*. Using Hardy's radiation method, cold and warmth thresholds were measured on the

forehead and trunk of subjects exposed to environmental temperatures from 15°C to 38°C. Subjects were nude and to allow for adaptation remained for 2 to 3 hours at the same temperature and experimental conditions while measurements were made. The wall temperatures were not significantly different from the air temperatures. The cold thresholds remained at a mean value of $27 \cdot 10^{-5}$ cal/sec/cm² in air temperatures of 15°C to 25°C, but increased with the air temperature from 25°C until at 38°C the cold threshold ($67 \cdot 10^{-5}$ cal/sec/cm²) was more than twice that of the cooler environments. By contrast, the warmth thresholds remained at the mean value of $30 \cdot 10^{-5}$ cal/sec/cm² throughout the range of air temperatures studied. This rise in the cold thresholds could not be explained by a change in the skin temperatures because at temperatures below 25°C the cold threshold remained constant while the skin temperature gradually increased with the air temperature. However, the plot of room temperature against cold thresholds closely followed the curves of increasing peripheral blood flow with temperature published by Hardy and Soderstrom. Thus, it is possible that hyperemia of the skin increases the threshold of cold sensation but has no effect on the threshold of warmth sensation.

Effects of over and underperfusion upon coronary arterial blood flow R ECKEL (by invitation), R W ECKSTEIN, M STROUD (by invitation), and W H PRITCHARD (by invitation) *Western Reserve Univ, Dept of Medicine, Cleveland, Ohio*. If the size of the coronary vascular bed and its resistance to blood flow depends upon the oxygen supply and demand, it should be possible to show resistance changes when the vessels are perfused at various pressures with cardiac work constant. With a special perfusion apparatus the left descendens, or left circumflex or total left coronary arteries of anesthetized, heparinized, open-chest dogs were perfused with blood at various pressures which were suddenly changed. Aortic and perfusion pressures were measured with Gregg manometers and coronary inflow with a Shipley recording rotometer or a Gregg and Green differential flow manometer. In some cases, when the total left coronary artery was perfused, sinus outflow was also measured with a second rotometer. The resulting flows show a rapid marked increase in vascular resistance within a few seconds following perfusion at pressures above aortic. Likewise, when perfused at pressures below aortic, there is a marked sudden reduction in vascular resistance. Since these changes, although slightly delayed, occur also in coronary sinus outflow, it is believed that they represent automatic changes in vascular resistance which serve to meet the metabolic demands of the myocardium.

Response of coronary blood flow following stimulation of cardiac accelerator nerves R W ECKSTEIN, M STROUD (by invitation), CHARLES V

DOWLING (by invitation), ROBERT ECKEL (by invitation), and W H PRITCHARD (by invitation) *Western Reserve Univ, Dept of Medicine, Cleveland, Ohio* In the anesthetized, open chest and heparinized dog cardiac output, coronary artery inflow or coronary sinus outflow, and aortic blood pressure were measured before and after stimulation of the left cardiac accelerator nerves The blood pressure was recorded with a Gregg optical manometer The coronary flow was measured with a Shipley recording rotometer Cardiac output was measured with a large Shipley recording rotometer placed in the thoracic aorta prior to ligation of the major proximal aortic branches Cardiac output was varied and controlled by inflating a balloon in the left auricle Control and experimental A-V differences between arterial and coronary sinus blood were determined

Stimulation of the accelerator nerves produces an increase in vigor of contraction, cardiac output, cardiac work, coronary blood flow, and oxygen consumption Simultaneous nerve stimulation and inflation of the left auricular balloon to reduce external cardiac work to below the control value is likewise followed by increased vigor of contraction, increased coronary flow, and increased oxygen consumption Therefore it is suggested that the adrenaline-like substance released by nerve stimulation markedly increases myocardial O_2 consumption and reduces cardiac efficiency Although direct effect of nerve stimulation upon coronary vessels must be considered, we have no evidence of increases in coronary flow in the absence of rising O_2 consumption

Effects of x-radiation on water and electrolyte metabolism in the rat ABRAHAM EDELMANN *Biology Dept, Brookhaven National Lab, Upton, L I, N Y* The intakes of distilled water, 1% NaCl solution, and food and the excretion of urinary Na, K, Cl and water by male albino rats were determined daily previous to and following exposures to 100, 250, 500, 800 and 1000 R of x-rays Polydipsia and polyuria occurred during the first and fifth 24 hour period following radiation The urinary excretions of Na, K, and Cl were increased at these times Following doses of 500 R or more there is a relative and absolute decrease in intake of the salt solution This is a monophasic response reaching its minimum at about 3 days The salt solution intake returns to previous levels at 5 days After doses of 100 or 250 R, the 1% NaCl solution intake follows the biphasic curve of water intake Food intake decreased for 2 days following radiation and then returned to normal in about 2 days Body weight changes paralleled the food consumption

Responses to vagal stimulation during hyperthermia H E EDERSTROM (introduced by A B Hertzman) *Dept of Physiology, St Louis Univ School of Medicine, St Louis, Mo* Dogs under anes-

thesia were heated to the lethal point by means of lamps During the rise in body temperature the peripheral ends of the cut vagi were stimulated and electrocardiograms and optical recordings of blood pressure taken The period of cardiac arrest due to vagal stimulation was reduced from several seconds at normal temperatures to a fraction of a second when rectal temperatures approached 45°C The fall in systolic blood pressure induced by vagus stimulation was relatively smaller at high body temperatures 'Vagus escape' was observed at all temperatures, but at $44-45^\circ\text{C}$ the rate of escape beats was about 3 times greater than those occurring during the same stimulation at normal body temperatures Stronger stimuli gave similar results In EKG tracings escape beats were characterized by absence of P waves when the right vagus was stimulated Beats recorded during left vagus stimulation were more like the normal pattern Bizarre and irregular QRST complexes were common in beats occurring during stimulation of the vagi at any temperature

Effect of haemorrhage on forearm blood flow and heart rate in man O G EDHOLM *Dept of Physiology, Univ of Western Ontario, London, Ontario, Canada* Sixteen normal subjects were bled from 250-1300 cc The withdrawn blood was retransfused approximately 4 hours later Forearm blood flow was measured with a plethysmograph, and graphic records were obtained throughout the experiments with a cardi tachometer During the period of haemorrhage, which lasted up to 30 minutes, there was no evidence of a diminished forearm blood flow except in one case whose control flows were high In the 7 subjects who fainted, the usual vaso-dilatation occurred during the faint Following the haemorrhage, in 9 non-fainters the forearm blood flow remained close to the control level for periods up to 4 hours In 3 subjects, the blood flow diminished significantly below control values, but only during a period when the mean blood pressure was reduced In the 6 subjects who fainted, the forearm blood flow remained at substantially control levels in 4 subjects In 2 subjects the mean blood pressure was reduced throughout the period of the experiment and the forearm flow was likewise diminished It was considered that these experiments indicated that the muscle blood vessels do not constrict to a significant extent after haemorrhage, and that there is no marked difference in this respect between fainters and non-fainters

Effects of certain physical factors on the in vitro gastric secretion of the dog CAROLAN TROWBRIDGE EDWARDS and LESLIE E EDWARDS (introduced by ROBERT W RAMSEY) *Dept of Physiology and Pharmacology, Medical College of Virginia, Richmond, Va* The method, previously reported, for in vitro gastric secretion has been improved and standardized, using the mucosa of the dog Dissec-

tion techniques and a method for pressure control are described by which it is possible to obtain more consistent data. It has been shown that secretion can take place in one direction only as reversal of the membrane results in complete failure of secretion. This method has been used to show the effects of temperature on the secretion rate.

Acid secretion by gastric mucosa of the bull frog in vitro LESLIE E. EDWARDS and CAROLYN TROWBRIDGE EDWARDS (introduced by ROBERT W. RAMSEY) *Dept. of Physiology, Medical College of Virginia, Richmond, Va.* Using the method for securing pure gastric secretion in vitro previously reported by the authors (*Federation Proc.*, 1948), acid secretion by the mucosa of the bull frog (*Rana catesbeiana*) has been obtained. pH values (as low as 1.5), free acid and total acid concentrations and titration curves are comparable to those for mammalian gastric juice. After an initial delay of about 1 hour, secretion with a pH of less than 2 can be obtained continuously for approximately 3 hours. Subsequently the pH gradually rises while the volume of secretion increases. Total chloride determinations indicate the presence of neutral chlorides as well as HCl.

Comparison of intracardiac and intravascular temperatures with rectal temperature LUDWIG W. EICHNA, ADOLPH R. BERGER and BERTHA RADER (introduced by DAVID P. EARLE, JR.) *Dept. of Medicine, New York Univ. College of Medicine, New York, N. Y.* In a study of the thermal gradients and deep tissue temperatures of 12 afebrile patients, thermocouples were introduced into the rectum, into the femoral artery and vein, and, by catheterization, into the right heart, pulmonary artery, superior and inferior venae cavae and the hepatic, subclavian and internal jugular veins. The data are presented as differences between the temperature of each intravascular site and the rectal temperature. Within the pulmonary artery, right ventricle, right atrium and femoral artery the temperatures usually were identical and averaged slightly less (0.2°C) than the rectal temperature. This difference, though small, was consistent and in 10 of 12 comparisons the intravascular values fell below the rectal values by 0.13°C to 0.34°C . Within the superior vena cava the temperature was lower than in the right heart, and in the subclavian vein its average value was 0.48°C below rectal temperature. Within the inferior vena cava the temperatures were variable and their average approximated closely that of the right heart. The temperatures deep in the hepatic vein and high in the internal jugular vein were considerably above the values in the veins into which these vessels drain and these hepatic and internal jugular vein temperatures equalled the rectal temperature. The data demonstrate the thermal gradients within parts of the vascular tree, indicate sites (liver, brain) of in-

creased heat formation at rest, and suggest that femoral arterial temperature is perhaps a more desirable index of 'mixed' deep tissue temperature than the usually accepted rectal temperature.

Photo-electric measurements of the arterial O_2 saturation dynamics in man for study of cardiopulmonary function J. O. ELAM (by invitation), J. L. EHRENHAFT (by invitation), W. N. ELAM, JR. (by invitation), and H. L. WHITE *Laby of Applied Thoracic Physiology (Surgery) and Dept. of Physiology, Washington Univ. School of Medicine, St. Louis, Mo.* Evidence favoring the use of histamine iontophoresis of the ear lobe for oximetry technique suggested a reevaluation of the saturation responses currently employed in the assay of cardiopulmonary function. Observations were made with the ear spectrophotometer and several experimental oximeters on the histamine flushed ear lobe and the heated pinna of normal subjects. The lung-to-ear circulation time measured from the inspiration of helium to the initial saturation decrease averaged 4.1 seconds when the histaminized lobe was used and 5.2 seconds when the heated pinna was used. Ear-to-ear circulation time measured from the initial saturation decrease with a single inspiration of helium to the secondary decrease after recirculation averaged 2.1 seconds with the histaminized lobe and 2.4 seconds with the heated pinna or lobe. The rate of saturation increase when subjects changed from air to oxygen was found to be significantly greater when the histaminized lobe was employed. In these measurements the period required for maximal saturation increase (saturation time) ranged from 15 to 30 seconds when determined from the histaminized lobe depending upon the minute respiratory volume. Using the heated pinna the saturation times ranged from 73 to 148 seconds in agreement with the Millikan data reported by others. The histaminized lobe technique provided significant saturation deflections within 4 to 7 seconds when hyperventilation, breath holding, and single inspirations of oxygen or nitrogen (interspersed during quiet air breathing) were performed. The technique using the histaminized ear lobe affords information more representative of arterial dynamics than does the conventional Millikan procedure.

Blood coagulation studies in relation to menstruation and menorrhagia RICHARD M. ELGHAMMER (by invitation), BURTON J. GROSSMAN (by invitation), PETER V. MOULDER (by invitation), ARTHUR K. KOFF (by invitation) and J. GARROTT ALLEN *Dept. of Surgery, Univ. of Chicago, Chicago, Ill.* A series of 183 coagulation studies were made on 52 women during their menstrual cycles. Sixteen women were considered normal in reference to menstruation, and 36 suffered from menorrhagia without apparent cause. The studies included the whole blood clotting time, prothrombin time, protamine

titration, platelet count, and observation for gross evidence of lysis. In the menorrhagic group, during menstruation, 82% showed a mild to moderate thrombocytopenia (29% with less than 100,000/mm³), 35 of 36 showed a prolonged whole blood clotting time, and 35 of 36 had an increased protamine titration. The intermenstrual studies on these women showed thrombocytopenia in 46% (8% below 100,000), 15 of the 36 had a prolonged whole blood clotting time, and 14 of 36 had an increased protamine titration. All patients had prothrombin values of 80% or better except two who had 72% and 76%. During menstruation 46% of the normal controls showed a mild thrombocytopenia. Nine showed slightly prolonged clotting times, and 5 of 16 had increased protamine titrations. Between menstrual periods 21% of the controls had mild thrombocytopenia. Six of the 16 had increased whole blood clotting times and 5 had abnormal protamine titrations. Evaluation of the extent of bleeding was made from careful clinical histories. Menstrual pads were not collected and analyzed for hemoglobin content.

Blood changes associated with cold diuresis
JOHAN W. ELIOT, RICHARD A. BADER and DAVID E. BASS (introduced by H. S. BELDING) *Quartermaster Corps, Climatic Research Lab., Lawrence, Mass.* Blood changes associated with cold diuresis were studied in conjunction with experiments on the renal and hormonal mechanisms of cold diuresis. The order of successive 2½-hour exposures to 27°C and to 15°C was alternated between men and in each man from day to day. In 23 experiments plasma proteins rose an average of 0.5 gm/100 cc, and the hematocrit rose 2.9% in the cold, in 12 experiments the corrected erythrocyte sedimentation rate rose 76% in the cold. In the experiments in which a warm exposure followed the cold these values fell an average of 0.5 gm/100 cc, 1.8% and 41% respectively. In 18 experiments on 5 men, the average increase in urine output in the cold over output in the warm was 287 cc, which corresponded to an accompanying average plasma loss of 277 cc as calculated from increases in plasma proteins and hematocrit and an estimated plasma volume of 50 cc/kg. However, a series of 15 experiments in which cold diuresis was largely or completely abolished by small doses of pitressin, but plasma proteins rose 0.4 gm/100 cc and hematocrit rose 2.6%, indicates that there is no direct connection between changes in urine output and plasma volume in the cold. Further indication is supplied by considerable individual variations, well outside the error of the methods, between increased urine output and calculated plasma volume loss. Plasma chloride levels showed no significant change during cold diuresis, despite the fact that in 11 experiments average total chloride output in the cold was 2330 mg, compared to 1279 mg in the warm.

Non-utilization of mannitol in uremic patients
J. RUSSELL ELKINTON *Dept. of Internal Medicine, Yale Univ. School of Medicine, New Haven, Conn.* Although 100% recoveries of mannitol in urine have been reported (Elkinton, *J. Clin. Invest.* 26: 1088, 1947; Clark and Barker, *Proc. Soc. Exp. Biol. & Med.* 69: 152, 1948), evidence has been presented for utilization or clearance from plasma by non-renal excretory routes (Berger *et al.*, *Proc. Soc. Exp. Biol. & Med.* 66: 62, 1947; Dominguez *et al.*, *J. Lab. Clin. Med.* 32: 1192, 1947). In 4 uremic patients given 25-45 gm of mannitol intravenously, little evidence of mannitol utilization was found for periods of 6 hours to 3 days. Mannitol utilized was calculated as the difference between the mannitol retained and the product of the conc. in serum water \times the original mannitol space corrected for changes in chloride conc. and balance. In patients 2 and 4 (anuric) utilization was less than the analytical error, and in patients 1 and 3 was less than 12% of the non-renal excretory clearance rate of 21 cc/min. calculated by Dominguez *et al.* Masking of utilization by an identical rise in serum blank, or failure of diseased kidneys to metabolize mannitol are alternative explanations.

PATIENT	MANNITOL				
	Time	Conc. Serum H ₂ O	Re-tained	Calc. in ECF	Utilized
	hr	mg %	gm	gm	gm
1	3	128.0			
	6.5	118.4	25.16	24.30	0.86
1	4	78.1			
	6.2	77.2	24.90	24.86	0.04
3	4	83.2			
	23	77.7	24.96	22.38	2.58
4	4	55.0			
	60	52.2	25.36	25.84	-0.48

Alterations in reflex muscular contractions induced by positive intrapulmonic pressure
LEONARD H. ELWELL (by invitation) and JOHAN W. BEAN *Dept. of Physiology, Univ. of Michigan, Ann Arbor, Mich.* The knee-jerks of young adult men, elicited by constant stimulation at 4-second intervals by a Lombard hammer, were recorded kymographically, together with spirometer tracing, thoracic and abdominal movements, and changes in blood oxygenation as determined by oximeter applied to the ear. Positive intrapulmonic pressure (20 cm H₂O) was applied through a rebreathing tank filled with room air and provided with soda lime canister and a pressure spirometer. Positive pressure was maintained for periods of about 3 to 7 minutes duration. Gentle application of pressure caused an immediate augmentation of the knee-jerk which persisted throughout the period of increased pressure, in several experiments the knee-jerk became

pendular in character. Respiratory minute volume was increased by a deepening and slowing of breathing, in some subjects frequency as well as depth was increased. The thorax was expanded in both its inspiratory and expiratory positions, in some cases the maximum inspiratory position was attained after several respiratory cycles rather than immediately. Thoracic respiratory movements were augmented. Changes in the abdominal region were in general similar to, but much less pronounced than, those of the thorax, except for a few cases where the abdominal circumference decreased rather than increased with positive pressure application. Changes in oximeter readings were so small as to be considered of little or no significance as causative factors in the reflex changes. All these effects were rapidly reversed on return to normal intrapulmonic pressure.

Separation of natural estrogens by counter-current distribution. LEWIS L. ENGEL (by invitation), WILSON R. SLAUNWHITE, JR. (by invitation), PRISCILLA CARTER (by invitation) and IRA T. NATHANSON. *Medical Labs. of the Collis P. Huntington Memorial Hospital of Harvard Univ. at the Massachusetts General Hospital, and Dept. of Biological Chemistry, Harvard Medical School, Boston, Mass.* Separation of the naturally occurring estrogens and in particular the separation of estrone from estradiol are difficult procedures. The development of the countercurrent distribution technique for the separation of closely related substances promised to aid in the simplification of this problem. Solvent systems consisting of ternary and quarternary mixtures were found in which a satisfactory spread of the partition coefficients of estrone, estradiol and estriol may be obtained. This makes possible a separation of the three urinary estrogens using a 24-plate distribution in the Craig countercurrent distribution apparatus. Other solvent systems were devised in which the partition coefficient of any one of the three compounds was nearly unity, thus placing the material in the optimum region for the detection of impurities. The partition coefficients of the three estrogens have been measured in the solvent systems employed in the isolation of the phenolic fraction from acid hydrolyzed urine. For these studies a fluorometric method based upon the procedures of Jailer and Bates has been used. With a Coleman Model 12-A Electronic Photofluorometer and a filter system consisting of a 436 m μ incident light filter and a 525 m μ interference filter for the emitted light, a full scale deflection of the instrument is obtained with 0.26 μ g of estrone, 0.36 μ g of estriol and 0.50 μ g of estradiol. The reaction is carried out by heating the estrogen in 1 ml of 90% sulfuric acid and diluting with 65% sulfuric acid. An accuracy of $\pm 10\%$ is obtained.

The hepatic venous circulation with special ref-

erence to the sphincter mechanism. H. E. ESSEX and W. D. THOMAS (by invitation). *The Mayo Foundation, Rochester, Minn.* The existence of a sphincteric or throttle mechanism in the hepatic circulation of the dog has long been recognized. Mautner and Pick believed the mechanism resided in the smaller hepatic veins. Bauer, Dale et al. held that it consisted of muscle rings in the hepatic veins near their confluence with the vena cava. The latter view has gained wide acceptance. A series of experiments made in this laboratory by Grana, Essex and Mann has shown that intact dogs are killed by intravenous doses of extracts of *Ascaris suum* that have little if any effect on a hepatectomized dog. It was also shown that the flow of blood through an isolated liver was arrested or markedly reduced by injections of such extracts into the portal vein. Casts made by injections of vinyl acetate into the hepatic blood vessels have shown that intravenous injections of extracts of *Ascaris*, histamine, digitoxin, horse serum into sensitized animals (anaphylactic shock) and occlusion of the hepatic artery for two hours cause intense spasm of the hepatic veins giving a cork-screw or spiral appearance, particularly to the casts of the smaller vessels.

In a series of exploratory experiments similar spasm of the hepatic veins has been produced in some but not all the cats injected and also in white rats. The data are insufficient to warrant drawing a final conclusion concerning this question except in the dog. In contrast with what occurred in the hepatic venous system the portal venous system shows marked engorgement.

Cholinergic nature of the vestibular receptor mechanism forced circling movements. C. F. ESSIG (by invitation), J. L. HAMPSON (by invitation), P. D. BALES (by invitation) and H. E. HIMWICH. *Medical Division, Army Chemical Center, Maryland.* Freedman and Himwich observed that the intracarotid injection of di-isopropyl fluorophosphate (DFP) produced righting movements in rabbits; the head turned away from the injected side and forced circling movements also in an adverse direction ensued while the homolateral pupil became miotic. Subsequent work revealed that the intracarotid injection of appropriate doses of freshly prepared DFP in normal saline under local procaine anesthesia, produced similar results in other species: guinea pigs, dogs, cats, and monkeys. Preliminary experiments indicate that the internal ear must be intact for the altered head posture and forced circling to occur; for labyrinthectomized rabbits failed to show the characteristic response following the injection of DFP on the labyrinthectomized side. A rabbit with unilateral section of the eighth nerve and a similarly prepared cat failed to exhibit the characteristic responses to DFP. Extirpation of the cerebral cortex on the in-

jected side did not prevent the syndrome if the vestibular apparatus was intact. The mechanism of vestibular stimulation is indicated by the drug used to produce the turning seizures for DFP is a powerful anticholinesterase agent which facilitates the accumulation of acetylcholine. Atropine and scopolamine which shield the organism from an excess of acetylcholine corrected the abnormal posture and stopped the forced circling movements.

Experimental production of femoral fractures

F. GAYNOR EVANS, HERBERT E. PEDERSEN, JOHN F. HAYES, and HERBERT R. LISSNER (introduced by M. MASON GUEST) *Dept. of Anatomy and Engineering Mechanics, Wayne University, Detroit, Mich.* Sixteen experiments were performed on 13 femora of white males and 3 of Negro females ranging in age from 45 to 85 years. 'Stresscoat' deformation patterns, with a lacquer sensitivity of 0.00125 inches per inch, and fractures resulted from static torsion loading, loading of the greater trochanter and cross-bending loading of the center of the shaft. Torsion loading produced spiral fractures of the shaft, cross-bending loading gave transverse comminuted fractures of the shaft, loading of the greater trochanter resulted in intertrochanteric, transverse neck, subcapital and abduction fractures of the neck and trochanteric region. In trochanteric loading bones from females fractured at 548.3 lb (average), males at 885.6 lb (average). Elevating the trochanter increased the load supported without fracture because the effective bending force on the shaft is decreased and the direct compressive force increased. Under similar test conditions in our small series, there was an inverse relation between load producing failure and age of the individual from whom the bones were obtained. Loads producing failure with torsion and cross-bending loading were approximately equal in magnitude and considerably less than those producing fracture when the greater trochanter was loaded. All fractures closely resemble similar types seen clinically. 'Stresscoat' deformation patterns indicated that all types, with the possible exception of the rare abduction fracture, resulted from failure of the bone under tensile stress.

In vitro metabolism of bone marrow in Ringer-bicarbonate medium containing no glucose. JOHN D. EVANS and ROBERT M. BIRD (introduced by EUGENE F. DuBOIS) *Dept. of Physiology, Cornell Univ. Medical College, New York, N. Y.* The aerobic metabolism of rabbit bone marrow has been studied *in vitro* at pH 7.3 in Ringer-bicarbonate media containing no glucose. The rate of oxygen consumption under these conditions is 3.6 microliters/mg of cell protein per hour. This is essentially the same rate as observed when glucose has been added to the system. Total aerobic acid production is small averaging 0.4 microliters/mg/hour. In the absence of glucose, small amounts of lactic

acid appear to be consumed, averaging 1.0 micrograms/mg/hour. The R.Q. averages 0.84 as compared with one of 0.95 obtained in the same system to which glucose has been added. The amount of total reducing substances in marrow under our experimental conditions is small. Its utilization averages 1.1 micrograms/mg/hour. Analyses for total amino acids and non-protein nitrogen give no evidence for protein breakdown. From these data it appears clear that carbohydrate and protein breakdown are not sufficient to account for the oxygen consumption of marrow in a medium containing no glucose. It is inferred that the breakdown of fatty substances is primarily responsible for this oxidation.

Lymph flow during edema formation. GEORGE FAHR and HERMAN KOSCHNITZKE *Minneapolis Gen. Hospital, Minneapolis, Minn.* The rate of lymph flow is a very important factor in reducing the rate of accumulation of edema fluid when ultrafiltration of plasma fluid into the interstitial spaces is accelerated. One of the three large lymph vessels near the ankle of a dog was cannulated and connected to the barrel of a tuberculin syringe before plasmapheresis. After plasmapheresis had been carried on for a period of 12 hours the colloid osmotic pressure was 5.8 mm Hg. The colloid osmotic pressure of the lymph collected from the cannula was 3.7 mm Hg. Before plasmapheresis it was only possible to get a lymph flow out of our cannula at the rate of 1 cc. in 9 minutes and 25 seconds when passive motion of the limb was carried out. Lymph flow after plasmapheresis was spontaneous and the rate was 1.5 cc. in 15 minutes. As there were 3 large lymph vessels the total flow of lymph from the foot of the dog was 0.3 cc. per minute. The weight of the foot from the point of cannulation down was 246 gm. or 1.2% of body weight. If we assume that the mean filtration pressure in the capillaries of the dog during these experiments was 22 mm Hg. and at the same time assume that the tissue pressure under these conditions of edema formation was 5 mm Hg. and then make use of Pappenheimer's filtration constant (Pappenheimer and Soto-Rivera, *Am. J. Physiol.* 152: 480, 1948) we calculate that 5 cc. of fluid would have been filtered per minute in the hind legs of a cat whereas we find 3 cc. lymph flow.

Resuscitation from fresh water drowning. DAVID C. FAIRER (by invitation), CLEMENT G. MARTIN (by invitation), HENRY SCHWARTZ, and A. C. ILLI *Dept. of Clinical Science, Univ. of Illinois College of Medicine, Chicago, Ill.* Studies on fresh water drowning have been made on dogs. The first stage lasting 68 seconds (mean), is characterized by struggling. The second stage, lasting 56 seconds (mean) is characterized by apnea or irregular respiratory movements. The third stage starting 124 seconds (mean) after submersion is ushered in by a precipitous fall in blood pressure which levels off

and reaches zero 259 seconds (mean) after submersion. No dogs survived after the precipitous drop in blood pressure occurred. Using an endpoint of 4 to 10 seconds after the cessation of struggling, no significant difference in survival was noted in dogs with a cannulated femoral artery if they received no resuscitation (survived 10, died 11), manual artificial respiration (survived 12, died 12) or artificial respiration with a mechanical alternating positive and negative pressure resuscitator (survived 12, died 8). In dogs without femoral artery cannulation, no significant difference in survival was noted if they received no resuscitation without postural drainage (survived 9, died 3), no resuscitation with postural drainage (survived 10, died 2) or artificial respiration with the alternating positive and negative pressure resuscitator (survived 4, died 2). Regardless of the measures employed, dogs having little or no staining of the lungs with methylene blue (added to the water used in drowning) survived, while those having dense staining died. About one-half of those dogs with moderate staining died. We interpret these results as indicating that mechanisms other than simple asphyxia play a role in drowning.

Oximeter measurements in pulmonary and cardiac disease J K W FERGUSON, D M FINLAYSON and I M HILLIARD *Dept of Pharmacology, Univ of Toronto, and the Toronto Western Hospital, Toronto, Canada*. Three measurements were investigated: 1) the difference in oximeter readings breathing air and breathing oxygen (A-O diff), 2) the time for the oximeter reading to change $\frac{1}{2}$ way to its final reading on changing from oxygen to air ($\frac{1}{2}$ R time), 3) the effect of exercise on the oximeter reading. The following groups of subjects were examined: a) 41 normals, b) 7 congenital heart cases, and then a group of miscellaneous pulmonary affections excluding tuberculosis and detectable cardiac disease, subdivided as follows: c) 20 lobectomies and pneumonectomies, d) 28 others showing no fall in O_2 saturation (less than 1%) on exercise, e) 27 others showing more than 1% fall in O_2 saturation on exercise. Group c included the most dyspneic. Out of 20 in group c, 12 had a fall in O_2 saturation on exercise. Average values for A-O diff \pm S.E. were as follows for each group: a) 4.0 ± 0.17 , b) 4.9 ± 0.24 , c) 3.17 ± 0.29 , d) 3.86 ± 0.24 , e) 4.94 ± 0.38 . For $\frac{1}{2}$ R time (in minutes) values were: a) 1.7 ± 0.07 , b) 0.9 ± 0.04 , c) 1.88 ± 0.22 , d) 2.82 ± 0.28 , e) 3.31 ± 0.23 . Group b had the greatest fall in O_2 saturation on exercise (8-22%, av 13.3%). Group c illustrates well the difference between pulmonary reserve and pulmonary 'efficiency'. Reserve is low, particularly in those who show a fall in O_2 saturation on exercise, while 'efficiency' is high in the same group, as shown by the low A-O diff and short $\frac{1}{2}$ R time.

Significance of activation of prothrombin in

serum JOHN H FERGUSON *Dept of Physiology, Univ of North Carolina, Chapel Hill, N C*. In spontaneous clotting of blood a variable and often considerable amount of prothrombin escapes conversion and persists, unlike the activated thrombin which is lost by the antithrombic mechanisms. In the presence of the suboptimal calcium content of serum, successive additions of optimal thromboplastin (brain extract) each activate some residual prothrombin to thrombin, which gradually disappears. The incomplete activations are proved by the repeated enhancement of coagulant activity, without exhausting the prothrombin even after 6 or more thromboplastin additions. However, if optimal Ca is added, complete exhaustion of prothrombin occurs after only 2 or 3 thromboplastin treatments. That more than one thromboplastin addition was found necessary suggests some 'antithromboplastic' activity of serum. The substrate for measuring thrombin activity in the above experiments was tested prothrombin-free ($BaSO_4$ -adsorbed fibrinogen). If a prothrombin-containing fibrinogen or plasma was used as substrate, an additional thrombin formation occurred which could be fully accounted for (as shown by control tests, minus serum) by transfer of Ca and thromboplastin in the serum activation mixture. Tests with suboptimal (1.2 mM) $CaCl_2$ were particularly significant since the extra thrombin from the substrate, in this case, was minimal. $BaSO_4$ -adsorbed serum (prothrombin-free) yielded no thrombin on treatment with Ca and thromboplastin (tests on prothrombin-free fibrinogen). With its natural suboptimal Ca and optimal added thromboplastin, this serum had no influence on the weak thrombin formation in prothrombin-containing substrates.

Tissue respiration in the polar cod (*Boreogadus saida*) as a function of temperature JOHN FIELD and C N PEISS (by invitation) *O N R Arctic Research Lab, Point Barrow, Alaska and Dept of Physiology, Stanford Univ, Calif*. The polar cod found off the north coast of Alaska is active at environmental temperatures as low as $-1.5^\circ C$. At such temperatures many temperate zone poikilotherms are in cold narcosis. The present study was designed to throw some light on the metabolic factors which must underlie the capacity for functional activity at these very low temperatures. Brain and liver were removed from over 100 polar cod of similar body size by the moist cold box technique. Measurements of the Q_{O_2} of whole brain mince and of liver slices were made at 0° , 5° , 10° , 15° , 20° and $25^\circ C$ by the Warburg method. For each organ the log Q_{O_2} -Centigrade temperature curve was approximately rectilinear over the range tested. Moreover the slopes of the curves were nearly the same. Comparison of the log Q_{O_2} -Centigrade temperature curve for polar cod brain with a similar curve for black bass brain mince (*Huro*

salmoides, habitat temperature about 18°C) established the following differences between these arctic and temperate zone forms 1) At each temperature the Q_{O_2} of polar cod brain was several times greater than that of black bass brain 2) The log Q_{O_2} -Centigrade temperature curve for bass brain showed a change in slope at 10°C, below this the slope was steeper (increase in Q_{10}), whereas the corresponding curve for polar cod had a constant slope from 0° to 25°C Both these differences as exhibited in the polar cod brain curve are advantageous in arctic adaptation

Blood production and iron reserves in man
STUART FINCH, DONALD HASKINS and CLEMENT A FINCH (introduced by M O LEE) *Dept of Medicine, Harvard Medical School, the Medical Clinic, Peter Bent Brigham Hospital, Boston, Mass* Five normal subjects were phlebotomized at weekly intervals During 7 weeks of bleeding, between 1 and 1½ gm of iron were removed from each subject About 800 mg of iron were mobilized for hemoglobin production during this time Measurements were made of the rate of blood production and of the various hematological changes during the period of bleeding and the period of recovery Available iron would appear to be the limiting factor in hematopoiesis Patients with large iron stores do not develop the degree of anemia shown by normal subjects However, previous prolonged iron feeding in 2 of the subjects had no effect on their ability to tolerate phlebotomy In those subjects who were allowed to spontaneously recover, serum iron values had not returned to normal in a period of 6 months These studies provide information regarding the rate of hematopoiesis in normal subjects under stress of phlebotomy, of the amount of available iron and of the time necessary to replenish the depleted iron stores

An anti-coagulant present in testicular extracts
S FISCH and E J TOWBIN (introduced by E F ADOLPH) *Dept of Physiology, Univ of Rochester, Rochester, N Y* Some crude hyaluronidase commercial preparations from bull testes were found to inhibit blood coagulation However, the anti-coagulant is not hyaluronidase but a non-dialyzable material precipitated by various concentrations of ammonium sulfate It is inactivated by heating at 65°C for 10 minutes The most potent preparation yet obtained, which has a very low hyaluronidase content, has an activity such that 5 mg of the dialyzed and dried precipitate will produce a 13-fold increase in clotting time of 1 ml of recalcified citrated human plasma or freshly drawn human blood The anti-coagulant is not heparin, for titration with salmine over a wide range of concentrations has no effect Moreover, the effects of these substances, in themselves anti-coagulants, are additive to those of the testicular substance It does not act by binding calcium It does not appear to

be fibrinogenolytic nor fibrinolytic It is neither anti-thrombic nor anti-prothrombic, these conclusions lending further support to the contention that it is not heparin It appears to delay clotting by acting as an antithromboplastic agent Only one other such agent has been described (Tocantins)

Electrophoretic study of the water soluble proteins of normal and atrophied muscles
E FISCHER, N J COPENHAVER (by invitation), B GALESKI (by invitation), and K W RYLAND (by invitation) *Baruch Center of Physical Medicine, Medical College of Virginia, Richmond, Va* Electrophoresis of the water-soluble proteins of normal gastrocnemii (rabbit) reveals 5 main fractions, of which 4 could be tentatively identified as myogen (43.6%), myosin β (24.3%), myosin α (15.1%), and myoalbumin (9.6%) The migration velocity at pH 7.5 increases in the above order, and the small unidentified fraction has a velocity between that of myosin α and myoalbumin During denervation atrophy, myoalbumin increases from the beginning, while myogen and the myosin fractions diminish considerably only after a delay of 10 to 12 days After 3 weeks of denervation, the myogen fraction and the myosin fractions are nearly halved, while myoalbumin is increased three to four times After tenotomy, myogen decreases and myoalbumin increases within 5 to 6 days as much as after 2 weeks of denervation Simultaneous denervation and tenotomy changes the electrophoretic pattern considerably less than simple denervation or tenotomy Enzymatic studies of the extracts confirmed that the combined operations damage the muscle less than the single operations

Sensibility of man to light anoxia
P E FISET (by invitation) and L P DUGAL *Dept d'Acclimation, Institut de Biologie Humaine, Univ Laval, Québec, Canada* Standard and objective psychological tests (concerning mechanical ability, space relations ability and survey of object visualization) were used in order to establish a difference in susceptibility to light anoxia (10,000 ft, 4 hours a week, 14 weeks) between 2 groups of human subjects receiving respectively, by demand valve system, oxygen and compressed air The results show that the progress in performance from the 1st to the 2nd trial is significantly better for the group receiving oxygen with all the tests used Confirmation using the same tests, and others, in the same conditions, has been obtained with 20 other human subjects

Production of constrictive pericarditis in dogs
A P FISHMAN, L H RUBENSTEIN, L W SENNETT, K KURAMOTO (introduced by L N KATZ) *Cardiovascular Dept, Medical Research Institute, Michael Reese Hospital, Chicago, Ill* Incident to the investigation of the cardiodynamics in congestive heart failure in dogs, it became necessary to establish a consistently effective method for the production of

constrictive pericarditis It was found that an envelope of polythene placed around the surface of the heart resulted in a rapidly progressive constrictive pericarditis with effusion Within 2 weeks neither coronary vessels nor auriculoventricular grooves could be identified The surface markings of the heart were completely obliterated Within 4 to 6 weeks, distended neck veins, hydrothorax, pulmonary congestion, hepatomegaly, ascites and peripheral edema uniformly ensued The predominance of any individual back-pressure manifestation varied with the site of intra-cardiac obstruction The polythene did not enter into the inflammatory reaction and could be readily removed from between the thickened, scarred pericardial surfaces If the polythene was not removed, the dogs died of constrictive pericarditis in 4 to 6 weeks An attempt was also made to induce pericarditis in the intact animal Thorotrast, injected under fluoroscopic vision, was used to outline the pericardial sac Sodium morrhuate was then injected intra-pericardially A sero-fibrinous pericarditis, without constriction, resulted The use of polythene provides a simple effective method for the production of a rapidly progressive constrictive pericarditis in dogs

Enzymes in the grasshopper egg LAURENCE ROCKWELL FITZGERALD (introduced by J H BODINE) *Zoological Labys, State Univ of Iowa, Iowa City, Iowa* The alkaline phosphatase of the developing egg of the grasshopper, *Melanoplus differentialis*, is shown to be apparently formed by the serosa and localised in the extra-embryonic fluid In comparing this with other enzymes studied during the development of this same material, it is found that the enzymes of the grasshopper egg fall into 3 groups a) Enzymes apparently of maternal origin, including methyl butyrase and tributyrinase These enzymes decrease in amount (or total activity) during development b) Enzymes which develop principally in the embryo This group includes cytochrome oxidase and cholinesterase c) Enzymes which appear during development, and which are found in extra-embryonic materials This group includes alkaline phosphatase, tyrosinase, and catalase The members of this last group are either undetectable, or barely detectable, in the embryo during development, but are swallowed, along with the extra-embryonic fluid just as the hatching process begins The failure to detect these enzymes in the embryo does not necessarily mean that they play no part in development, as Haldane has shown, using data on saccharase, that a relatively small number of enzyme molecules may be sufficient for the normal functioning of a cell

A small plastic tubing technique for right and left heart catheterization H F FITZPATRICK, T G SCHNABEL, JR, and L H PETERSON (introduced

by H C BAZETT) *Dept of Physiology, Univ of Pennsylvania Medical School, Philadelphia, Penna* By the use of small plastic tubing, cardiac catheterization can be accomplished by a simplified procedure without skin incision and without apparent risk of venous thrombosis In dogs, a routine venipuncture of the right external jugular is done with a special 18-gauge needle the lumen of which permits the passage of a small plastic catheter The needle then is withdrawn As the catheter is advanced slowly toward the heart, continuous ink recordings of venous pressure gradients can be obtained with a capacitance manometer Without fluoroscopic guidance satisfactory measurements of right auricular and ventricular pressures may be made From a manifold of 3-way stopcocks, blood samples for analyses can be withdrawn at a rate of 1 ml or more per minute Left ventricular pressures in dogs can be obtained by an open method, using a long, 18-gauge, olive tipped needle which is introduced, via the common carotid artery, to a level 1 inch above the aortic valve Through this needle, a small plastic catheter is advanced beyond valve and into left ventricle The needle is then withdrawn The characteristics of this relatively short and very small plastic tubing permits reliable recordings of pressure waves which probably are not inferior to those obtainable by the much larger and longer catheters commonly used This method of right heart catheterization is being evaluated on man with the purpose of determining cardiac output Simultaneous electrocardiograms are made

Thiocyanate and mannitol space and native ionic balance in acute adrenal insufficiency JAMES B FLANAGAN (by invitation) and R R OVERMAN *Division of Physiology, Univ of Tennessee College of Medicine, Memphis, Tenn* It has been suggested that the urinary loss of Na and Cl in untreated adrenalectomized dogs is insufficient to account for the total reduction of these ions in extracellular fluid Similarly, it has been proposed that urinary water loss in this condition is insufficient to explain the apparent extracellular dehydration Simultaneous measurement of the volume of fluid available for the dilution of NaSCN and mannitol combined with flame photometric analyses of Na and K and chemical analysis of Cl in plasma and erythrocytes makes possible the calculation of the total amount of 'extracellular' Na and Cl in 1) normal dogs, 2) dogs in acute adrenal insufficiency, and 3) adrenalectomized dogs maintained on DCA Together with Na, Cl and water intake and output studies, it was calculated that on the average, the total 'extracellular' Na of adrenalectomized dogs maintained on DCA was 568 mm The average total 'extracellular' Na of dogs in acute adrenal insufficiency was 347 mm Thus the average total reduction in 'extracellular' Na was 221 mm Since the dogs showed an

average negative Na balance (intake minus output) of but 50 mm, an average of 171 mm of Na remains unaccounted for. Similarly the total 'extracellular' Cl averaged 433 mm in dogs maintained on DCA and but 273 mm in dogs in acute insufficiency. The difference between these figures is 160 mm. However, the dogs showed an average negative Cl balance of but 79 mm, thus leaving 81 mm of Cl unaccounted for.

Persistence of hypertension after removal of the causative ischemic kidney. JACK FLASHER (by invitation) and DOUGLAS R. DRURY, *Dept of Physiology, School of Medicine, Univ of Southern California, Los Angeles, Calif.* Persistent hypertension develops in the rabbit as a result of unilateral renal ischemia. If this ischemic kidney is removed after the hypertension has lasted some time, the blood pressure does not necessarily revert to normal, but may continue above normal for several weeks. A control group of normal rabbits subjected to unilateral nephrectomy did not show any significant change in blood pressure after the operation. The findings support the view that a hypertension that has lasted some time tends to be self-perpetuating, persisting for an appreciable time after the original cause has been removed.

Comparison of heptazone (4,4-diphenyl-6-morpholinoheptanone-3-hydrochloride) with other analgesic drugs. LARS FLATAKER (by invitation) and CHARLES A. WINTER, *Merck Institute for Therapeutic Research, Rahway, N. J.* Comparisons have been made between heptazone, dl-methadone, dl-isomethadone, and morphine, for analgesic activity, toxicity, analgesic tolerance, and side effects. Heptazone, orally or parenterally, proved to be about twice as potent as methadone in rats, though of relatively short duration, but only half as potent as methadone in dogs. Isomethadone gave less consistent results than the other drugs. The outstanding advantage of heptazone was its low acute toxicity. LD₅₀ in mice (subcutaneously) averaged 210 mg/kg, compared with 33 mg/kg for methadone. When dogs were dosed twice daily (heptazone 4 mg/kg, other drugs 2 mg/kg) analgesic tolerance appeared in about a month. Side effects, such as narcosis, sedation and general depression, were most marked with methadone and morphine, much less with heptazone, and least with isomethadone. Nausea and vomiting occurred frequently in non-tolerant dogs given morphine, occasionally in methadone-treated dogs, but was never observed after heptazone or isomethadone. After analgesic tolerance was established, dose for all drugs was doubled. The increased dose was well tolerated by all dogs except those receiving methadone. Dosing was continued for 4 months, the drugs withdrawn for 1 month, then a second course of injections was given. After analgesic tolerance was

established the second time, cross-tolerance studies were made. With the doses used, dogs tolerant to morphine were also tolerant to heptazone and isomethadone, but not to methadone. Those tolerant to methadone or isomethadone were tolerant to all the other drugs. Dogs tolerant to heptazone were tolerant to morphine and isomethadone, but only partially tolerant to methadone.

Fractional conditioning of behavior based on electrically induced convulsions. STEPHEN FLECK (by invitation) and W. HORSLEY GANTT, *Pavlovian Lab., Phipps Psychiatric Clinic, Johns Hopkins Univ., Baltimore, Md.* Three dogs were subjected to electric convulsions through 2 cephalic jelly plate electrodes. Two auditory stimuli were given: one 15 seconds before shock (inhibitory), the other 5 seconds before shock (excitatory). Approximately 30 experiments/dog were made during 2 months. The dogs became increasingly resistant and negativistic to the experimental situation. Specifically there was fighting with other dogs, hostility towards the experimenters and increased motor activity outside the camera. Inside in connection with environmental stimuli the dogs manifested extreme motor activity with struggling in the hammock and running movements, at times indistinguishable from motor phenomena observed during and after convulsions. The animals disregarded injury and the movements seemed purposeless. Stimuli that brought on this behavior were 1) the experimenter leaving the camera and 2) the 'inhibitory' stimulus. The 'excitatory' stimulus caused no specific reaction except occasional orienting responses. The respiratory tracings often paralleled the motor excitement following stimuli 1) and 2) cited above, i.e. the tracings approached the pattern seen during convulsions. Occasionally jerking of the hind legs occurred after these stimuli. The negative reaction to the 'excitatory' stimulus with preservation of the reaction to the 'inhibitory' stimuli is evidence of amnesia for the 5-second pre-convulsive period—comparable to the retrograde amnesia in patients after shock and after head injuries. The conditioning of certain motor phenomena with failure to condition the total convulsive behavior demonstrates fractional conditioning, rather than complete duplication of the UR by the cr.

Studies on colchicine derivatives: toxicity and antimitotic effect. W. FLEISCHMAN, A. GOLDIN (by invitation), B. GOLDBERG (by invitation), L. G. ORTEGA (by invitation), A. D. BERGNER (by invitation) and G. E. ULLYOT (by invitation), *Medical Division, Army Chemical Center, Maryland, Dept of Preventive Medicine, Johns Hopkins Univ. School of Medicine, and the Smith, Kline and French Labs., Philadelphia, Penna.* Colchicine arrests mitosis in metaphase. In view of the great

toxicity of this compound it seemed of interest to investigate the antimutagenic effect of some of its derivatives. Toxicity was determined by intraperitoneal administration. Mice were implanted subcutaneously with sarcoma 180. Tumors were 7 days old at the time the animals were sacrificed, 6 hours after injection of various compounds. Corneal mitoses were studied on flat preparations. Spermatogonia were studied on pre-fixed smears stained with acetic orcein. The following compounds were studied: Colchicine (1), trimethylcolchicinic acid methyl ether d-tartrate (2), colchicine (3), trimethylcolchicinic acid (4), N-benzoyltrimethylcolchicinic acid methyl ether (5), N-benzoyltrimethylcolchicinic acid (6), and N-acetylcolchicinol (7).

COMPOUND	LD ₅₀ mg/kg	LOWEST DOSE (MG/KG) AFFECTING MITOSIS		
		Cornea	Spermatogonia	Sarcoma 180
1	3.5	0.35	0.35	0.88
2	64.0	3.2	3.2	3.2
3	84.0	84.0	21.0	21.0
4	200.0	inactive	200.0	200.0
5	20.0	35.0	1.0	5.0
6	>700.0	inactive	inactive	inactive
7	56.0	28.0	14.0	—

The relationship between chemical structure, toxicity and antimutagenic activity will be discussed.

Intravenous aminophylline and coronary blood oxygen. ELWOOD L. FOLTZ, ALAN J. RUBIN and WILLIAM A. STEIGER (introduced by CARL F. SCHMIDT) *Dept. of Pharmacology, Univ. of Pennsylvania, Philadelphia, Penna.* In 10 normal intact dogs under morphine-nembutal anesthesia, coronary sinus catheterization was accomplished under fluoroscopic guidance (*Am J Physiol* 152: 341, 1948). Simultaneous arterial and coronary venous blood samples were collected during control periods and after injection of either saline or aminophylline. Following intravenous aminophylline, coronary venous O₂ saturation fell from 30.2% to 17.7% (mean values) and the unsaturation (A-V difference) rose from 62.1% to 74.1%. Compared with results where saline was injected, these data showed significant differences. No marked change was noted in mean arterial blood pressure, but the mean pulse rate increased from 145 to 165 beats per minute. Electrocardiographic records revealed no significant change in pattern as a result of catheterization or experimental procedures. Since previous studies demonstrated that the myocardial stimulating effect of aminophylline increases cardiac output and cardiac work, it is suggested that aminophylline increases cardiac oxygen consumption more

than the augmented coronary flow increases the delivery of oxygen.

Narcosis and refractory phase in certain cerebral mechanisms. A. FORBES, A. F. BATTISTA (by invitation), P. O. CHATFIELD (by invitation) and J. P. GARCIA (by invitation) *Harvard Medical School, Boston, Mass.* Stimulation of the sciatic nerve in cats under deep barbiturate narcosis has previously been shown to evoke a primary electric response in the sensory leg area of the cortex and a secondary discharge, more widespread in the cortex, with latencies from 30 to 80 milliseconds. When a series of stimuli is applied at more than 4/second, each stimulus evokes a primary response, but only the first evokes the secondary discharge. A rest of nearly a second is needed before another stimulus can evoke the discharge. This behavior resembles the Wedensky inhibition in peripheral nerve, in which a partial block stops all but the first of a series of impulses so frequent that each impulse after the first falls in the relative refractory phase following its predecessor and is therefore subnormal.

Our experiments dealt with the question whether the failure of all stimuli after the first of a rapid series to evoke a secondary discharge is likewise due to subnormal impulses encountering a partial block in the cerebrum. Increasing the depth of narcosis greatly prolonged refractory phase in the mechanism of secondary discharge and decreased the stimulus frequency required to hold the discharge in abeyance. We found nothing inconsistent with the view that the effect is essentially a Wedensky inhibition. Depression of blood pressure, respiration and cortical waves was related to blood analysis of narcotic, and from the combination of these observations the rate of elimination of narcotic was estimated, this provided a measure of the depth of narcosis.

Comparison of pharmacological activities of several antihistaminic agents. ROBERT T. FORD, SHIRLEY L. MCHUGH, VIRGINIA M. O'ROURKE, DOROTHY J. NIXON and GERALD Q. O'NEILL (introduced by KARL H. BEYER) *Medical Research Division, Sharp and Dohme, Inc., Glenolden, Penna.* Tripeleminamine hydrochloride, Pyranisamine Maleate, Antergan, Thenylpyramine hydrochloride, Prophepyramine hydrochloride, R.P. 3277, and several other compounds have been evaluated on the basis of their local anesthetic, antihistaminic, antiacetylcholine, and antihyaluronidase activities. The antihistaminic tests include the antagonism of the effect of histamine against the isolated guinea pig ileum, the isolated guinea pig tracheal chain, and the histamine blood pressure depression in intact dogs. The local anesthetic measures include the rabbit cornea and the electrical stimulation of the isolated rat nerve-

diaphragm preparation. The hyaluronidase test was the inhibition in rabbits of the effect of hyaluronidase on the intradermal spread of India ink. The antiacetylcholine test was the antagonism of acetylcholine stimulation of the isolated rabbit ilium. The data suggest that of these measures, other than the strictly antihistamine tests, the inhibitory effect of these agents on the spreading induced by hyaluronidase may be a relatively important factor in anticipating clinical efficacy.

Indirect estimation of cardiac output in man from carbon dioxide exchange. CYRIL A. FORSSANDER (by invitation), HERBERT KRAMER (by invitation), C. J. MARTIN (by invitation), COLIN WHITE (by invitation) and H. C. BAZETT. *Dept. of Physiology, Univ. of Pennsylvania Medical School, Philadelphia, Penna.* Recent reports have demonstrated a wide range in arteriovenous differences in blood from various organs, with a consequent contrast between the compositions of superior and inferior caval blood. Any vaso-motor reflex, or change in mechanical conditions, is liable to alter the composition of mixed venous blood by changing the relative proportions of different streams, consequently in estimating venous alveolar air tensions it is probably important not to ask the subject either to make any effort or to change his respiratory pattern. Simple rebreathing of a high oxygen mixture, adopting these precautions, sometimes gives indications of a short plateau in CO_2 tension after some 20 seconds, but this is particularly difficult to demonstrate in shallow (and relatively rapid), also in deep (tho relatively slow) breathers. Attempts are being made to demonstrate plateaus in all types of subjects by reducing the volume of gas used for rebreathing to a minimum (in which Scholander's micro method for gas analysis aids) by utilizing a double bag system to accelerate mixing in the lungs (according to Gladstone's Principles), and thirdly by use of various experimental mixtures of oxygen and carbon dioxide. Cardiac outputs have been calculated from such estimates of virtual venous alveolar air, arterial alveolar air and carbon dioxide output. The values so obtained have usually been higher than those reported by users of the old acetylene method.

Electrolyte and protein changes during acute pneumococcal infection in rats. CHARLES L. FOX, JR. and GILBERT ASHWELL (introduced by ALFRED GILMAN). *Dept. of Bacteriology, College of Physicians and Surgeons, Columbia Univ., New York City.* Metabolic balance studies of Na, Cl, K, N and H_2O were made on individual rats infected intraperitoneally with a minimal dose of virulent pneumococci to ascertain some of the chemical changes that occur in a typical bacterial infection,

terminating in death in 4 to 5 days. Within the first 24 to 48 hours after infection, the excretion of Na, Cl and K increased 250 to 1000% above the pre-infection levels. On the 3rd and subsequent few days of survival, the Na and Cl excretion dropped to much below the pre-infection values, and occasionally to nil, in marked contrast, the greatly increased K excretion continued until death. There was a steady loss of body weight of from 12 to 19% and nitrogen excretion decreased progressively. The rats reduced their intake of food and water after the second day and urine output gradually diminished. All balances after infection became negative. The net loss of K was especially large and increased steadily until death occurred. It is of interest that in one instance of spontaneous recovery, these changes occurred initially but on the 4th day the weight loss ceased, K excretion approached zero and, as the K balance became positive, body weight returned to normal. Tissue analyses were made of samples taken from moribund rats at a time when other rats had already died. Tissues from uninfected rats carried on the same diet to control the metabolism studies were also analyzed. Muscle tissues from infected animals showed a marked elevation in K content, the intracellular compartment appeared to have increased and the extracellular components decreased.

Electrolyte, nitrogen and protein changes that follow massive removal of red cells and plasma protein. CHARLES L. FOX, JR. and BETTY B. FREEMAN (introduced by ALFRED GILMAN). *Dept. of Bacteriology, College of Physicians and Surgeons, Columbia Univ., New York City.* In a study of the chemical sequelae of acute blood loss and hypoproteinemia in dogs, from $\frac{3}{4}$ to $\frac{1}{2}$ of the blood was removed in 3 hours and replaced with mixtures of salts and water. The concentrations and balances of H_2O , Na, Cl, K, nitrogen and protein were determined before and after the massive hemorrhage. A most noticeable result was a 50% decrease in plasma K concentration followed by excretion of considerable K in the urine during the first 24 hours after bleeding. One to two days later, K excretion became extremely low while nitrogen excretion, which had been subnormal at first, rose sharply. Thus the K/N ratio initially became very high (10 to 15/1), then became very low (0.8/1) and after a few days returned to normal (3-5/1). The Na and Cl values were high or normal depending upon the volume and composition of solution infused but equilibrium was achieved rapidly. The massive blood removal resulted in hematocrit values ranging around 10% and plasma proteins ranging around 1.3 gm/100 cc, nevertheless the dogs survived, no edema resulted and both red cells and proteins regenerated. When K was in-

cluded in the replacement solution (5 mEq/l) the fall in plasma K was only partly counteracted and the K excretion was unaltered, the added K, however, seemed to reduce both the tachycardia and the volume of infusion needed to prevent circulatory collapse and renal failure

Growth and O₂ consumption, as affected by X-irradiation, using the bacterium, *Serratia marcescens* ANN C FOWLE (by invitation) and KENNETH C FISHER *Univ of Toronto, Toronto, Canada* The growth of the bacterium, *Serratia marcescens*, is accompanied by an increased rate of oxygen consumption, from which presumably it derives energy for growth. When the bacteria are subjected to X-irradiation various disturbances of growth and cell division are produced. It has been found that although the bacteria which grow and divide after irradiation do so at a rate considerably slower than normal, they do so without any appreciable interference with the amount of oxygen associated with growth. Thus it appears that the primary effect of X-irradiation does not involve the energy reactions specifically concerned with growth.

Factors affecting constancy of vasomotor response to repeated intra-arterial injections of mecholyl and of epinephrine LEWIS FRANKLIN (L I M R Fellow) (by invitation), HOWARD WAYNE (by invitation), J MAXWELL LITTLE and HAROLD D GREEN *Dept of Physiology and Pharmacology, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N C* In evaluating vasomotor responses induced reflexedly or directly by chemicals, in dogs anesthetized with sodium pentobarbital, we have compared these responses with responses to standardized quantities of mecholyl or epinephrine. Venous outflow was measured at 10 sec intervals from the physiologically isolated hind leg, perfused from the dog's own arterial system. To determine the constancy of response 116 intra-arterial injections of 0.08 μ g of mecholyl were made in 9 experiments and 35 injections of 1.0 μ g of epinephrine in 6 experiments. In intact preparations the coefficient of variation (coef var) for the maximum change of flow per 10 sec interval was 12-41% (av 22.6%) for mecholyl and 7-53% (av 28.5%) for epinephrine. Severance of both vagi and both carotid arteries or the sciatic and femoral nerves did not improve the coef var. Expressing the response as percentage change increased the coef var to 29.4%, when expressed as total change in flow (cc of blood flow gained or lost) the coef var was 27.0%. At constant control flows, the response to both drugs, expressed as maximum change of flow, decreased with decreasing perfusion pressure. At constant perfusion pressures, the response to mecholyl decreased but to epinephrine increased with

increase in control flow. Enough data are not yet available in which results were obtained at constant control pressures and flows to draw definite conclusions but the coef var appears to be about 10%. Another cause of variability may be the development of refractoriness near the end of prolonged experiments.

Further lowering of glucose tolerance following an induced hypothyroid state in Yale rats THOMAS F FRAWLEY and CHARLES W BISHOP (introduced by GEORGE F KOEPF) *Dept of Medicine, Univ of Buffalo School of Medicine, and Medical Research Labs, Buffalo General Hospital, Buffalo, N Y* A significant percentage of Yale-strain rats have been shown to have an abnormally low glucose tolerance. Sayers and Sayers (*Am J Physiol* 141:466, 1944) postulated that this diminished tolerance might be due to an inherited hyperactivity of the adrenalmedullary system. Studies were undertaken to determine the influence of thyroidectomy or propylthiouracil on this impaired glucose tolerance. The goitrogens provide a more specific method for studying the influence of hypothyroidism on carbohydrate metabolism heretofore equivocal with thyroidectomy due to the high percentage of aberrant thyroid tissue. A 35% solution of glucose (350 mg/100 gm body weight) was administered intraperitoneally and blood glucose determined at intervals over a 5-hour period. One group of 5 Yale rats weighing 200-400 gm was thyroidectomized and to another similar group propylthiouracil (0.10 gm/100 gm body weight) was administered daily by stomach tube. Glucose tolerance was determined at weekly intervals over a 5-week period. The average values (mg %) for each group are shown in the following table.

HOURS	0	$\frac{1}{2}$	1	2	4	5
(T) Before	90	326	228	134	104	97
(T) After 5 weeks	89	395	420	295	200	164
(P) Before	80	280	243	154	102	119
(P) After 5 weeks	80	354	310	228	136	114

(T) = Thyroidectomy group

(P) = Propylthiouracil group

Quantitative measurement, by external counting, of the I¹³¹ content of the thyroid gland in man A. STONE FREEDBERG, ALVIN URELES and MARVIN VAN DILLA (introduced by HERRMAN L. BLUMGART) *Med Res Lab, Beth Israel Hospital, Dept of Medicine, Harvard Medical School, and Dept of Physics, Mass Inst of Technology, Boston, Mass* We have recently described a method for quantitative measurement of I¹³¹ content of the thyroid gland in man by external counting. Independence of size and location of the thyroid gland (depth geometry and absorption) was achieved by con-

necting in parallel 4-6 platinum cathode Geiger-Mueller counters, arranged in a horizontal plane in circles of varying radii. With these counters in a circle 36-120 cm in diameter, a central source of radiation was moved about within a sphere 8-32 cm in diameter concentric with the circle of counters, the maximum variation in counting rate was 5%. When the source was surrounded by muscle, bone, water and saline in quantities approximating the human neck there was no significant change in counting rate. With a constant amount of radioactivity in volumes varying from 5-350 cc in different shaped containers no significant change in counting rate was observed. Identical amounts of I^{131} in 5 cc and in 2,000 cc of water placed in gallon jugs showed a decrease of 5% in the counting rate in the latter instance.

Preliminary studies on thyroid uptake in patients with varying gland size are consistent with mock up experiments. With a circle 52 cm in radius $10 \mu c$ in the thyroid gland gives a counting rate 2.5 background. Following a standard oral dose of $150 \mu c$, I^{131} carrier-free, the thyroid uptake and urinary I^{131} excretion was studied in 22 subjects. Thirteen thyrotoxic patients demonstrated, at varying times up to 48 hours, a maximum uptake in the thyroid gland from 46-84% and averaged 66. In 7 euthyroid subjects the uptake ranged from 13-39% and averaged 30. In 2 myxedema patients the thyroid uptake was 1 and 4%. Preliminary studies on the rate of uptake in the thyroid gland have also been carried out and are described.

Effect of Eck fistula formation and meat intoxication on serum phosphatase and dye clearance of adult dogs. SMITH FREEMAN, *Dept of Exptl Medicine, Northwestern Univ Medical School, Chicago, Ill.* The average preoperative Rose-Bengal dye-clearance of 19 adult dogs was 107 units and their serum phosphatase averaged 2.4 Bodansky Units. The minimum dye clearance after Eck fistula formation averaged 53 units and the corresponding phosphatase values averaged 9.9 units. Meat intoxication was produced in 10 of 11 dogs of the preceding series. The average serum values prior to meat intoxication were dye clearance of 51 units and phosphatase of 6.6 units. A diet of raw horse meat (50 gm/kg) produced meat intoxication in an average of 9 days. The average dye clearance decreased to 34 units and the serum phosphatase increased to 18.8 units. These changes are construed as evidence of further liver injury in the Eck fistula dog.

Summation of stimuli studied with the aid of anticholinesterases. JEANE SISKEL FREY (by invitation) and ROBERT GESELL, *Dept of Physiology, Univ of Michigan, Ann Arbor, Mich.* The carotid nerve was stimulated repetitively at frequencies ranging from 10 to 50/sec and the effects of this

stimulation on breathing recorded with the aid of a Hutchinson spirometer. Progressive increase of frequency of stimulation was attended by an increase of temporal summation of stimuli as shown by the increased respiratory response. Similar gradation of frequency of stimulation following administration of anticholinesterases (physostigmine, DFP, X substance (Army Chemical Center) and CO_2) was attended by an appreciably greater summation of stimuli at all frequencies. Potentiation of temporal summation by anticholinesterases agrees with an acetylcholine sparing action at synapses and a consequent intensification of neurocellular current which are believed to generate nerve impulses (current report of Hunter, Lillie and Gesell). Since anticholinesterases impair conduction of impulses in nerve fibers (Gilman, Nachmansohn, and Lowe and Gesell) it is unlikely that they potentiate reflexes by improved conduction of nerve impulses in the dendrites and cell body. For the reason that these reagents potentiate rather than depress central nervous activity, our experiments support earlier conclusions of Lowe and Gesell that impairment of impulse conduction in nerve and muscle by anticholinesterases is incompatible with the theory of synaptic conduction of nerve impulses. It is suggested that our experiments agree with the concept of specialization of function in the neuron.

Can transfer rate be calculated from urine isotope ratio? HERBERT D. FRIEDLANDER (by invitation) and WALTER S. WILDE, *Physiology Dept, Tulane Univ School of Medicine, New Orleans, La.* The expression for calculating transfer rate is $P^*/P = \Delta n_1^*/\Delta n_1 = \Delta n_2^*/\Delta n_2 = \dots = \Delta n_n^*/\Delta n_n$. P^*/P is the instantaneous ratio for tagged and for total but exchangeable chemical in the plasma. $\Delta n^*/\Delta n$ is the ratio of the respective chemicals, as infinitesimals, accumulated in the organs 1, 2, etc., or in an excreted fluid e, urine, saliva, etc. The amount of exchange back and forth of intrinsic substance, Δn , cannot be measured directly in most systems. It must be calculated from the equation. Certain excreted fluids such as urine, however, represent a continuous one-way sampling of Δn . Thus we measure Δn^* and Δn directly in urine collected over the transfer period and substitute them in the equation to calculate Δn_1 in an organ. This obviates estimation of P^* as \bar{P}^* from the area under a plasma time-concentration curve for tracer.

\bar{P}^*/P and $\Delta n^*/\Delta n$ were compared in 16 rats after subcutaneous tracer phosphate. Before 35 minutes \bar{P}^*/P exceeds $\Delta n^*/\Delta n$. Non-tracer phosphate lying in the urinary channels at injection time probably contaminates Δn . Later $\Delta n^*/\Delta n$ for the full period exceeds \bar{P}^*/P often threefold even at 150 minutes. Govaerts (*Arch Int Pharmacodyn*

75 261) presents evidence or non-exchangeable dog plasma phosphate. Calculations from his data agree with ours \bar{P}^*/P in plasma acid filtrates of the rat equals that in magnesium precipitates prepared in the cold. Faster urination of phosphate during the plasma peak hardly explains the result. Radiocalcium data sent by Govaerts yield similar \bar{P}^*/P and $\Delta n^*/\Delta n$ values.

Inactivation or removal of insulin by the liver
A. FRIEDMAN (by invitation), H. F. WEISBERG (by invitation) and R. LEVINE, *Dept. of Metabolic and Endocrine Research, Medical Research Inst., Michael Reese Hospital, Chicago, Ill.* Under normal circumstances insulin, after leaving the pancreas, reaches the liver before it goes into the general circulation. We wished to determine whether any inactivation or removal of the hormone occurred during its passage through the liver. For this purpose we have injected insulin into dogs at a constant rate I.V. ($0.1 \mu\text{g}/\text{kg}/\text{hr}$) over 2-hour periods, by two injection routes—the splenic vein and the femoral vein. Blood sugar values were estimated at 15–30 minute intervals. Each dog served as its own control. The results show that insulin infused via the splenic vein had, in all cases, a significantly smaller effect on the arterial blood sugar levels than did the insulin infused via the femoral vein. It is estimated from the areas of the curves that the liver led to removal or inactivation of about 40% of the injected insulin. These experiments were made with Lilly insulin which contains variable amounts of a hyperglycemic factor which might have been the cause of the lessened effect of intrasplenic insulin. However, identical experiments with a brand of insulin (NOVO) which we found not to have the hyperglycemic factor, also gave the lessened intrasplenic response.

Gastrointestinal motor effects of intestinal extracts
M. H. F. FRIEDMAN, *Dept. of Physiology, Jefferson Medical College, Philadelphia, Penna.* The experiments were performed on dogs under sodium pentobarbital, ether, or urethane anesthesia. Motor activities were recorded by means of tandom balloons and water manometers from the antrum, duodenum, terminal ileum, and colon. All tissue extracts were administered by vein. Certain preparations of intestinal mucosa, in doses of 2 to 10 mg/kg, always increased the tonus and force of contractions. This effect apparently occurred throughout the whole gastrointestinal tract but not in other smooth muscles. The response was obtained within a latent period of 2 minutes and was sustained for 10 to 45 minutes. Some evidence of tachyphylaxis was obtained. The motor effects were not abolished by bilateral vagotomy, splanchnectomy, separation of the intestine into segments, or large doses of atropine. No synergism between effective extracts and pilocarpine or mecholyl was

noted. The motor effects were not due to histamine and probably not to choline. The effective principle was not found in extracts of gastric mucosa, or in other types of intestinal mucosa extracts. It could be concentrated from intestinal extracts made by the method of Greengard et al. for the preparation of enterogastrone, and was found present in a commercial preparation of "purified enterogastrone" which is available for the treatment of peptic ulcer. The results suggest, but do not prove, the presence of a gastrointestinal motor 'hormone' in the intestinal mucosa.

Role of the adrenal cortex in the excretion of purines
MEYER FRIEDMAN, DONALD BERNSTEIN (by invitation), and SANFORD O. BYERS (by invitation), *Harold Brunn Inst. for Cardiovascular Research, Mount Zion Hospital, San Francisco, Calif.* Twenty-eight rats (maintained on water containing sucrose 5%) were given 100 μg of an extract of adrenal cortex (Lipo-Adrenal Cortex-Upjohn) by intramuscular injection. It was found that the total renal excretion of purine increased approximately 25% during the first 24 hours following the above injection. Six rats, injected with DOCA (5 mg/kg), showed no appreciable increase in purine excretion during the next 24 hours. Twelve rats were nephrectomized and given the same amount of Lipo-Adrenal Cortex. Four nephrectomized rats were given DOCA. The total purine content of the blood of these 16 animals 24 hours after injection was no greater than that of 14 control nephrectomized rats. These observations suggest that Lipo-Adrenal Cortex effects in rats an increase in the excretion of purines which is of renal origin.

Emotional state on acquired and inborn reactions: satiation on cardiac conditional reflexes and unconditional reflexes to food
W. HORSLEY GANTT, *Pavlovian Lab., Phipps Psychiatric Clinic, Johns Hopkins Univ., Baltimore, Md.* In the laboratory the conditional reflexes maintain a mechanical constancy comparable to the physiological reflexes so that they can be expressed even in a formula. Outside the laboratory the reactions are characterized by extreme variability and apparent lawlessness. The explanation is to be found chiefly in the strict control of the state of the animal used in the laboratory. Our previous investigations showed that the salivary conditional reflexes (*crs*) were dependent upon the state of hunger of the animal, falling from a maximum to zero immediately after satiation. The cardiac *cr* has been measured in this laboratory for many years to study the inner emotional state of the animal contrasted with the more specific external *crs*. Several dogs with well established food *crs* were allowed to eat to satiation after taking control salivary and cardiac measures to the condi-

tional signals for food. An immediate decrease of the cardiac *cr* resulted from the satiation. The cardiac component of the unconditional reflex (*UR*) was only slightly affected (the animal would not eat after satiation unless the food were forced into the mouth). Satiation caused an elevation of control cardiac rate. For example before satiation 'Sechs' control heart rate = 85, *cr* = 110, *UR* = 110, after satiation control heart rate = 100, *cr* = 108, *UR* = 105. In 'Peik' before satiation control heart rate = 65, *cr* = 98, *UR* = 95, after satiation control heart rate = 85, *cr* = 95, *UR* = 110. The cardiac component of the inhibitory *crs* was not affected. It is thus evident that not only the specific salivary *crs* but the more generalized emotional *cr* components, represented by the heart rate, may be immediately abolished by a change of emotional state of the animal while the *URs* are much less affected.

Anoxia on conditional reflexes in dogs W. HORSLEY GANTT, GEORGE W. THORN and C. DORRANCE. *Pavlovian Lab., Phipps Psychiatric Clinic and Dept. Medicine, Johns Hopkins Univ., Baltimore, Md.* Changes in higher cerebral function caused by single exposures to moderate altitudes (18,000 ft) are difficult to measure because of inadequate testing methods. Two dogs aged 11 and 4 years were exposed 4 hrs. to both 18,000 and 25,000 ft, either by reducing pressure or reducing oxygen content. One dog was exposed in a pressure chamber 6 times, the other 5 times. Responses measured were based on food ('Sechs') or pain ('Connie'). Sechs at 18,000 ft showed a reduction of the conditional reflex (*cr*) from 238 σ control in the pressure chamber to 170 experimental, inhibitory *cr* remained 0. At 25,000 ft the disturbance was more severe, excitatory *cr* = 150 σ , inhibitory = 135. After 24-hr recovery impairment persisted, excitatory *cr* = 205, inhibitory = 48 σ . Connie having *crs* to painful stimulus, gave as control 83% correct motor responses to excitatory *cr*, 3% to inhibitory *cr*. At 18,000 ft no impairment, at 25,000 ft excitatory *cr* = 90% correct but inhibitory *cr* = 60%—disturbed differentiation. After 24 hr there was complete recovery. Although differences according to age, temperament and kind of reflex measured, in both dogs there was marked impairment at 25,000 ft, but in the younger dog not at 18,000 ft. *Cr* measurements can be useful in evaluating efficacy of therapy for altitude tolerance. The *cr* impairment appears when there is no other observable neurological change.

Spinal cord pathways and connections for sensory fibers from the knee joint of the cat ERNEST GARDNER (introduced by M. MASON GUEST). *Dept. of Anatomy, Wayne Univ. College of Medicine, Detroit, Mich.* Recordings were made from the dorsal surface and ventral roots of the

spinal cord following electrical stimulation of the posterior nerve from the knee joint of the cat. With single shocks, potential changes characteristic of internuncial activity were recorded from approximately the 3rd lumbar to the 1st or 2nd sacral segments. These potentials were maximal in the 6th and 7th lumbar levels. Reflex discharges were recorded from ventral roots of those segments in which considerable internuncial activity was observed. Recordings were also made of action potentials in the posterior nerve conducted antidromically after single shocks to dorsal funiculi at various levels. Results indicate that articular fibers, after entering the spinal cord, synapse with internuncial neurons in several cord segments. These neurons in turn relay to motor neurons and also to lateral spinothalamic tracts. In addition, collaterals from the larger of the entering fibers ascend in dorsal funiculi as far as the medulla oblongata, beyond which they were not traced. In the lumbar cord, the fastest conduction rates were 90–100 m/sec. At the cervical cord, however, conduction was from 35–50 m/sec. The endings from which these ascending fibers are derived are Ruffini-type endings in the capsule of the posterior part of the joint.

Physical and chemical properties of emulsifying agents in urine JOSEPHINE B. GARST (by invitation) and HARRY B. FRIEDGOOD. *Dept. of Medicine, Univ. of Calif. at Los Angeles, Calif. Inst. for Cancer Research, Los Angeles, Calif.* The urinary material which stabilizes oil-in-water emulsions encountered in extraction of urine with organic solvents has been separated by full saturation with ammonium sulfate at pH 5. The flocculent brown precipitate which forms can be separated more rapidly by addition of ether and shaking. The precipitate is separated from the urine and reprecipitated twice from distilled water by addition of acetone to 80% concentration. It is then washed at the centrifuge with small amounts of water. When centrifugation no longer sediments the material, it is precipitated finally with acetone. The precipitate is then dried in vacuo over sulfuric acid. The product is hydrophilic, has a total nitrogen content of 10%, gives positive Molisch, xanthoproteic and biuret tests. A solution of the separated precipitate in distilled water stabilizes an ether-in-water emulsion. On the other hand, the residual urine at pH 5, freed of the above material, does not form emulsions with ether. Electrophoresis of the product has been conducted at pH 8.6 in 0.1 molar barbiturate buffer. The soluble fraction consisted of two components in the ratio of approximately 3 to 1. The characteristics of the material suggest that it consists predominately of glyco-protein.

Electrocorticograms of the cytoarchitectural

areas of macaca mulatta JOHN S GARVIN and L V AMADOR (introduced by PERCIVAL BAILEY) *Dept of Neurology and Neurological Surgery, Univ of Illinois College of Medicine, Illinois Neuropsychiatric Institute, Chicago, Ill* Investigators have noticed differences in electrical activity from various cytoarchitectural areas during other electroencephalographic experiments. Specific studies have been made on rabbits and cats. The cortex of *Macaca mulatta* was exposed and direct recordings made in anesthetized, unanesthetized and curarized animals. Electrical activity from various areas revealed marked differences. There were minor variations between animals, but in general the following holds. The tracings from areas *FA* (Area 4) and *PC* (Area 1) are quite distinctive, but indistinguishable from each other. The entire occipital region is lower in amplitude than any other region. *OC*, *OB* and *OA* (Areas 17, 18, 19) are practically alike except that the amplitude of *OA* is slightly higher. Activity is similar throughout all of *TA* (Area 22), and is not characteristic. The activity of *FB* (Area 6) is of high amplitude and resembles the activity from the inferior parietal region, while the activity from *FD* (Areas 10, 9) and *FD delta* (Area 46) is of rather low amplitude with some faster superimposed activity. Tracings from some areas, notably *PEm* (Area 5), *PE* (Area 7), *PF* (Area 40) and *PG* (Area 39) were indistinguishable, but were characteristic for those regions. Multiple simultaneous recordings within *FA* revealed 'Dial bursts' at one point and not at another and at times almost synchronous bursts throughout the area. No particular difference between the unanesthetized, curarized and anesthetized monkeys was observed except that the frequency in *FA* and *PC* appeared faster under curarization and without anesthesia.

Action of D O C A and adrenal cortical extract on body water and kidney function MARIO GAUDINO and MARVIN F LEVITT (introduced by HOMER W SMITH) *Dept of Physiology, New York Univ College of Medicine, New York City* Three normal dogs were injected with 30 mg of D O C A for 3 weeks and the changes in extracellular space (inulin vol of distribution), total body water (D_2O), intracellular space (difference between D_2O and inulin vol), plasma vol (T-1824) and renal function (inulin and PAH clearances, Tm_{PAH}) were studied frequently. There was a marked increase in the extracellular space with no change or slight decrease in the total body water, resulting in a significant decrease in the intracellular space. Plasma volume slightly increased or showed no change. Inulin clearance increased, PAH clearance increased very slightly and Tm_{PAH} was significantly decreased. The first change to appear was the increase in extracellular space. A fairly

good correlation exists between the inulin clearance and the inulin space. With the prolongation of treatment the above changes tended to disappear, despite an increase in the dose of D O C A. After the injections were discontinued the return to normal was complete. Two dogs treated with 15 cc of total adrenal cortical extract (Upjohn) revealed a completely different effect. The extracellular space did not change significantly, but the total body water increased markedly, reflecting an absolute increase in the intracellular space. Plasma volume, inulin and PAH clearances did not change. Tm_{PAH} increased in one case and decreased in another. All changes were reversed after the treatment was discontinued.

Arterial oxygen saturation and intracardiac pressures during acceleration in relation to cardiac damage O GAUER (by invitation), J P HENRY, E E MARTIN (by invitation), P J MAHER (by invitation) *Aero Medical Lab, Air Materiel Command, Wright-Patterson Air Force Base, Dayton, Ohio* A fall in arterial oxygen saturation has been predicted during acceleration in view of the marked disturbances in lung circulation observed in X-Ray motion pictures. Therefore, in both human and animal experiments oxygen saturation in arterial blood has been continuously recorded during acceleration. A Kramer glass cuvette oximeter with an automatic syringe has been employed together with Van Slyke determinations of blood oxygen content. A fall from 97% to 90% in oxygen saturation was measured in a human exposed to 4.5 g positive acceleration for 15 seconds. Experiments in anesthetized dogs submitted to both positive and negative acceleration showed changes of the same order during brief acceleration and even greater changes during prolonged runs (2 min). Intracardiac pressures were simultaneously recorded in both ventricles of nembutalized dogs during negative acceleration, using modified pressure sensitive tip Wetterer catheters. Carotid and jugular pressures were also recorded in these experiments. These measurements were an attempt to correlate the above mentioned fall in arterial saturation with the frequent development of subendocardial ecchymoses in the left and right ventricles during negative acceleration. During the acceleration there were changes in the contour of the right intraventricular pressure wave suggesting that at certain periods during the cardiac cycle the changes in right intraventricular pressure may fall out of phase with those occurring in the left ventricle. Such pressure differentials between the heart chambers during acceleration indicate a possible mode of origin of the above mentioned ecchymoses.

Utilization of fructose by the perfused brain of the living cat A GEIGER, J MAGNES, R M

TAYLOR and H. WAELSCH (introduced by H. GRUNDFEST) *Depts of Biochemistry and Psychiatry of New York State Psychiatric Inst., New York City* Fructose penetrates into the narcotized cat's brain up to concentrations of 60-100 mg/100 gm, if the fructose concentration of the blood is kept very high (15-2%) for an hour or more. When the normal blood circulation of the cat's brain was switched over to perfusion with a glucose-free suspension of erythrocytes in a Ringer solution containing 100 mg of fructose and 7 gm bovine serum albumin/100 cc the following was observed. The oxygen consumption of the brain was about half as great as with the same perfusion fluid containing glucose. The glucose from the brain disappeared at a rate corresponding roughly to the rate of oxygen consumption. As long as glucose was present in the brain the fructose concentration in it remained unchanged. Only after the complete disappearance of glucose did the fructose concentration slowly diminish. The amount of oxygen consumed during this period was larger than that required for the oxidation of fructose. The larger part of the oxygen consumed during the glucose-free period could be as preliminary experiments indicate, accounted for by the disappearance of glutamine and glutamic acid from the brain cortex.

Differences in cortically and subcortically induced convulsions. ERNST GELLHORN *Lab of Neurophysiology, Dept of Physiology Univ of Minnesota, Minneapolis, Minn* **Cortically induced convulsions.** Convulsive activity induced by topical application of strychnine does not interfere with the independence and asynchrony of different cortical areas either under control conditions or in asphyxia. **Subcortically induced convulsions.** First, strychnine is injected into either hypothalamus (mammillary body) or thalamus (dorsomedian or ventrolateral thalamic nucleus) in 'Dial' cats and local spikes are recorded. Hereafter asphyxia is initiated which causes the spikes to disappear first and the normal potentials later. During this time the asynchrony existing between various cortical and subcortical areas persists unchanged. After cortical potentials have disappeared a synchronous outburst is recorded in cortex, thalamus, basal nuclei and hypothalamus and lasts for 10 to 30 seconds. This discharge consists of convulsive spikes and is accompanied by overt convulsions in the non-curarized cat. The experiments suggest that the subcortical focus does not control cortical activity as long as the cortical excitability remains normal. If, however, cortical potentials disappear the subcortical focus seems to be released (removal of cortical inhibition) and leads to a generalized synchronous discharge. **Systemic convulsions.** If generalized convulsive

activity is induced by intravenous injection of picrotoxin asphyxia leads to synchronous cortical and subcortical discharges as observed in experimental group 2.

A skin resistance recorder or sudomotor. WILLIAM A. GEOHEGAN (introduced by Joseph C. Hinsey) *Dept of Anatomy, Cornell Univ Medical College, New York City* Measurement of skin resistance provides a convenient index of sudomotor activity, and recording of skin resistance changes is of great value in determining nervous pathways. While in some cases an approximate measure of skin resistance is desirable, in others, it is important to record small changes due to an applied stimulus. An instrument has been developed which permits measurements of both kinds, is simple to operate and is safe for application to human subjects in the operating room. A set of interlocking push buttons permits connection of any one of 5 electrodes to a bridge and vacuum tube voltmeter which is calibrated directly in ohms. The voltmeter output is connected through a stable d.c. amplifier to an Esterline Angus recorder. Sensitivity and stability are adequate for recording changes as small as 1%, and permit detecting presence of relatively few fibers in a stimulated pathway. A convenient balancing arrangement is provided to center the recorder for any resistance value from 1000 ohms to 100 megohms. The instrument is operated from the 115 volt a.c. line and employs no batteries. Electrical and mechanical isolation of the input circuit insure against accidental application of high voltage to the patient.

Cholinesterase activity of intact nerve, DFP inhibition. R. W. GERARD, B. LIBET and D. CAVANAUGH *Dept of Physiology, Univ of Chicago and Marine Biological Lab., Woods Hole, Mass* The inertness of ACh applied to nerve has been attributed to lack of penetration. Also, an objection raised to the measured ChE inhibition, on grinding a nerve soaked in DFP, has been that the inhibitor and enzyme react after structural breakdown. The following experiments invalidate these points. A frog sciatic or a single squid giant axone is threaded through a capillary, with cut ends outside. The capillary is filled (about 20 cu mm) with a dilute ACh solution, or (squid axone) a measured drop of the solution is moved to and fro along the nerve. After desired intervals at room temperature the ACh solution is removed and ACh assayed. With unpoisoned nerve or axone, 65 to over 80% of the ACh present (0.1 to 1.28) had disappeared in 20 minutes. Controls show that no ChE leaves the tissue, so ACh must have reached the enzyme in intact fibers. Despite adverse conditions (low ACh concentration, long diffusion distances, part time contact) this corresponds to a QChE of over one-fourth the full value of a squid axone. When

10 mM DFP was present in the ACh solution, no ACh loss was found in 60 minutes with frog nerve. Conduction remained normal.

Species reactivity of staphylocoagulase and staphylokinase EARL B GERHEIM (by invitation) and JOHN H FERGUSON *Dept of Physiology, Univ of North Carolina, Chapel Hill, N C* A study was made of sheep, cattle, rat, dog, horse, guinea pig, chicken and rabbit plasmas in connection with the staphylococcal factors concerned in coagulation (prostaphylocoagulase) and lytic activity (staphylokinase). The lengthened staphylocoagulation times, as well as the complete incoagulability of some plasmas was due to 1) an inhibitor to the active clotting agent, staphylocoagulase, 2) destruction of fibrinogen by proteolytic activity due to activation of a proenzyme by the factor staphylokinase, and 3) a possible low co-factor content. Fractionation of the plasmas with ammonium sulfate indicated that the inhibitor was quite ubiquitous, with the globulin fractions containing the most. No fraction of any species except rabbit contained as much cofactor as could be obtained from human plasma or serum. The fractionation procedure seemed to inactivate a great deal of the inhibitor. Parallel tests for fibrinolysis with staphylokinase and streptokinase were made. Staphylokinase, which has previously been shown to activate a proenzyme in human serum, was reactive with a proenzyme found in rabbit, guinea pig and dog serum. Streptokinase did not activate any proenzyme of the species tested, except human. Staphylokinase differs from streptokinase in requiring a long incubation period for maximal lytic activity. The greatest proteolytic activity was developed in dog serum.

Biophysics of the cochlea B E GERNDT (by invitation), J S RIESCO-McCLURE (by invitation) and H DAVIS *Central Inst for the Deaf, St Louis, Mo* Aural microphonics were recorded simultaneously from the round window of guinea pigs and from another electrode placed in a very small hole drilled into the scala vestibuli or media of the apex or one of the intermediate turns. Pure tones of various frequencies were adjusted in intensity to give a standard response of 20 microvolts at the round window. The necessary sound intensity was noted, and the corresponding voltages of the microphonic at the other electrode were measured. In several experiments the cochlea was then injured through another small hole at some intermediate position and measurements repeated. The logarithms of responses at apex (with round window response constant) plotted as a function of log frequency yield a smooth curve that is nearly horizontal below 1000 cps and falls off more or less rapidly as frequency is increased. Apical and round-window responses are usually equal at about

3000 to 4000 cps. Intermediate positions of the electrode yield similar curves with less low-tone emphasis. Injury abruptly increases the intensity required to produce a standard response to the frequencies that correspond in position to the position of injury. The relations of position of electrodes and of injuries to frequency correlate well with those previously established by Stevens, Davis and Lurie. Even a severe injury, however, rarely raises the necessary intensity more than 20 db. The significance of these and related observations to the biophysics of the cochlea are discussed.

Fractionation of enterogastrone concentrates with N-butyl alcohol LEON L GERSHBEIN (by invitation), HUGH M MILLEN (by invitation) and A C IVY *Dept of Clinical Science, Univ of Illinois College of Medicine, Chicago, Ill* A number of enterogastrone concentrates purified by way of the tannate (ET) as well as by subjecting the latter to picric acid treatment (EP), were submitted to alcohol fractionation. The extraction of these products with successive portions of aqueous alcohol and absolute methyl alcohol led to high recoveries of the starting materials with little enrichment of the hormone, as based on the continuous histamine assay method. However, at least a two-fold enrichment occurred with n-butyl alcohol. In fact, 50 mg of one concentrate which gave a gastric stimulatory response in excess of 80% yielded a butanol extract eliciting 43% and 52% inhibition with 25 mg doses. The yields of these fractions aggregated 13-14%. The procedure employed is exemplified by the following run. A mixture of 2.00 gm of ET-16 and 200 ml of butyl alcohol was mechanically stirred for 20 minutes at 32°-38°C. After filtration by centrifugation, the supernatant liquid was concentrated to 16 ml and treated with 110 ml of acetone. The precipitate which was washed by centrifugation with portions of acetone, then 1:1 acetone-ether and finally ether, weighed 268 mg (13.4% recovery). Further fractionation of the butyl alcohol-soluble product was afforded by treatment with methyl alcohol. The 22% soluble portion was highly stimulatory to the dog, whereas the methylalcohol-insoluble fraction in a 25 mg dose inhibited gastric secretion to the extent of 70% in the same dog.

Heating of tissues by near and far infrared radiation JEROME W GERSTEN (by invitation), KHALIL G WAKIM, RICHARD W STOW (by invitation) and ADRIEN N PORTER (by invitation) *Sections on Physical Medicine and Physiology, Mayo Foundation and Mayo Clinic, Rochester, Minn* It has been widely accepted that near-infrared radiation is more efficient in heating human tissues than is far-infrared. Because the evidence does not seem convincing a comparative

study of the heating effects of irradiation with energy in the far-infrared and near-infrared ranges was made. Tissue temperatures were recorded by means of copper-constantan thermocouples, and the radiant energy density at the skin surface was determined by means of a radiation thermocouple. Near-infrared rays were produced by a 250-watt Mazda bulb, and far-infrared rays by a 450-watt carborundum heater. The energy absorption/volume of tissue was calculated at the end of one minute of heating. With both sources of heat, the skin absorbed the greatest amount of energy, and the muscle the least, as computed/volume of tissue. When the radiant flux density at the skin surface was almost identical, the energy absorption by the tissues was 22% greater with the carborundum unit than with the Mazda bulb. The distribution of the energy absorption was the same with both sources, thus indicating that the effectiveness of the carborundum heater was not due to marked cutaneous heating with relatively little deep heating. When the output of the carborundum unit was decreased by 43.5%, the energy absorption by the tissues was decreased 40.8%, thus indicating that when the same heater is used the energy absorbed is directly proportional to the energy radiated. Judged by the increase in temperature of tissues to a depth of 15 mm, this study showed that far-infrared radiation is more efficient than near-infrared radiation.

Tissue distribution, excretion and metabolic fate of chloramphenicol (chloromycetin). ANTHONY J. GLAZKO, LORETTA M. WOLF (by invitation) and WESLEY A. DILL (by invitation). *Research Labs of Parke, Davis and Company, Detroit, Michigan.* Chloramphenicol is an aromatic nitro compound for which chemical and microbiological assay procedures have been developed. The chemical method is based on reduction of the nitro group to a primary amine with metallic zinc or titanous chloride, followed by diazotization and coupling. It is suitable for determination of total drug in biological material, since it includes inactive degradation products as well as unchanged chloramphenicol. The drug is rapidly absorbed, with serum levels reaching a maximum in about 2 hours and falling gradually during the next 18 to 24 hours. Analysis of tissues in the rat and dog reveal high concentrations in the kidney and liver, with progressively lower concentrations in the lung, spleen, heart, muscle and brain. Unchanged chloramphenicol has been isolated from the urine of man and identified. About 5% of the administered dose is recovered in 24-hour urine specimens by microbiological assay, whereas 80 to 92% is recovered by chemical assay, indicating the presence of large amounts of inactive nitro compounds. A simple hydrolysis product of chloramphenicol

and a conjugate have been identified in urine. The conjugate was found to regain antibiotic activity following hydrolysis with a glucuronidase preparation. No increase in aryl amine excretion was observed in the urine of man or dog, but lower animals showed a significant rise. Incubation of chloramphenicol with rat liver slices *in vitro* resulted in loss of activity, with the formation of inactive nitro compounds and a small amount of aryl amine.

Site of action of soy bean trypsin inhibitor on the coagulation system of blood. MARY BETH GLENDENING and ERNEST W. PAGE. *Dept of Obstetrics and Gynecology, Univ of California Medical School, San Francisco, Calif.* Soy bean trypsin inhibitor (SBTI) markedly inhibits the rate of blood coagulation, and also protects animals against the toxic effects of intravenously administered thromboplastin. The findings of Tagnon (1946) and Macfarlane (1947) that the site of action is on some factor involved in the conversion of prothrombin to thrombin have been confirmed. The effect on thrombin is negligible. Initial experiments with plasma collected in silicone-coated apparatus indicated that the SBTI affected a plasma constituent as well as thromboplastin. A 2-stage technic with purified prothrombin as substrate and dilute beef serum as a source of accelerator globulin was utilized in order to identify this constituent. Thrombin formation ceases at approximately the same time regardless of the presence or absence of SBTI. The amount of thrombin formed, however, varies directly with the concentration of beef serum and inversely with the concentration of SBTI. Thromboplastin, freed of Ac-globulin is inhibited similarly but the amount of thrombin formed is much lower than when beef serum is present. In the absence of beef serum the phospholipid extracted from purified thromboplastin will not convert prothrombin to thrombin, although it becomes increasingly active with rising concentrations of beef serum. This suggests that an active constituent of beef serum, presumably Ac-globulin, can qualitatively substitute for a protein portion of thromboplastin. Present evidence supports the concept that both a phospholipid and a protein are essential for any appreciable conversion of prothrombin to thrombin, and that SBTI acts on both the protein moiety of the thromboplastin molecule and the serum Ac-globulin.

Effect of pteroylglutamic acid and 4-amino pteroylglutamic acid on the growth of sarcoma 180. A. GOLDIN (by invitation), B. GOLDBERG (by invitation), L. G. ORTEGA (by invitation) and L. B. SCHOENBACH. *Biology Sect., Medical Div., Army Chemical Center, Md., and the Dept of Preventive Medicine, The Johns Hopkins Univ. School of Medicine, Baltimore, Md.* The ability of folic acid (pteroylglutamic acid) to reverse the effect

of aminopterin (4-amino-pteroylglutamic acid) induced inhibition of the growth of sarcoma 180 was tested. Groups of mice bearing transplanted sarcoma 180 were treated with aminopterin plus a series of concentrations of folic acid. The weights of the tumors were compared with the tumors of mice which received aminopterin alone, folic acid alone, and with the tumors of control groups. A partial reversal of the aminopterin induced inhibition of tumor growth by administration of folic acid was a constant finding. The tumors of aminopterin treated mice averaged 35% of the controls. The tumors of mice treated with aminopterin, plus folic acid ranging in concentrations from 5-50 mg/kg, were 65-75% of the weight of the controls. Folic acid itself appeared to produce some inhibition of tumor growth when administered at higher concentrations. The reversal of aminopterin inhibition by folic acid is reflected in the histological appearance of the tumors. Tumors of mice treated with folic acid did not show the marked histological changes resulting from aminopterin inhibition, but approximated that of the control tumors.

The reflexology of the pudendal nerve field
 CHARLES H. GOOD (introduced by BERRY CAMPBELL) *Dept of Anatomy, Univ of Minnesota, Minneapolis, Minn*. Previous work on the reflexology of the spinal cord has dealt principally with the locomotor apparatus—the lumbo-sacral intumescence and the neuro-muscular apparatus of the hind limbs. Noteworthy are the fast components of the reflex in these locomotor fields and the absence of direct transmission of activity across the midline of the cord. The pudendal nerve mediates the sexual reflexes and other reflexes of the perineal-anal region. The effector structures are near the midline and frequently work in conjunction with their antimeres. Central latency is long, crossed return is the rule. Stimulation of the penis of cats results in an efferent discharge, crossed and uncrossed along the S₂ and S₃ ventral roots. The total latency to S₂ ventral root is 8.2 msec of which 2.2 msec is afferent conduction time. Crossed intersegmental as well as crossed segmental return is found. The forms of the reflexes are to be shown as well as their conditioned activity. *Parallel anatomical study of the fiber spectrum of the pudendal nerve and its roots is being made.*

Myocardial lactate and pyruvate metabolism in dogs under severe stress
 WALTER T. GOODALE and DONALD B. HACKEL (introduced by W. FLEISCHMANN) *Physiology Sect., Medical Div., Army Chemical Center, Maryland*. Development in this laboratory of a technique of coronary sinus catheterization (*Am J Physiol* 152: 340, 1948) has made possible the study of myocardial

metabolism in intact nembutalized and unanesthetized dogs. Removal of metabolites from coronary blood was assumed to represent myocardial utilization, which was then calculated from the product of two apparently independent variables: 1) Coronary blood flow, measured by the nitrous oxide method, and 2) Coronary arterio-venous difference, estimated from simultaneous femoral arterial and coronary venous blood samples. Severe stress from adrenalin infusion, shock, hemorrhage, severe anoxia, convulsions, and severe nutritional deficiency all caused a rise in arterial lactate levels above normal, but removal of lactate from coronary blood by the myocardium was greatly reduced, occasionally even to zero at arterial lactate levels of 40 to 60 mg %. Pyruvate removal was only moderately reduced. Although decreased lactate removal may indicate decreased myocardial lactate utilization, adrenalin release may be the common denominator in such situations of severe stress, leading to glycogenolysis within the heart (and liver), with endogenous production of lactate as an immediate emergency source of energy, with high tissue lactate levels produced endogenously, the myocardium should remove less lactate from coronary blood as the blood-to-tissue concentration gradient falls. Failure of the myocardium to remove lactate from coronary blood at elevated arterial lactate blood levels is apparently associated with a grave cardiac emergency, and often with a threat to survival.

Reduced synthesis of phosphocreatine in tissue homogenates from alloxan diabetic rats
 E. S. GORANSON (introduced by R. E. HAIST) *Dept of Physiology, Univ of Toronto, Toronto, Canada*. The phosphorylation of creatine, under aerobic conditions, has been studied in homogenates of various tissues of the rat, principally brain, incubated for short periods at 37°C. In the presence of added succinate, cytochrome C and adenosine triphosphate, the synthesis of phosphocreatine in preparations from alloxanized rats is significantly less than in those from normal animals. Insulin injected into the alloxanized rats prior to tissue sampling was found to promote an increased formation of phosphocreatine. Similar results have been obtained when malate and pyruvate are substituted for succinate in the homogenates. Insulin had no appreciable effect on the oxygen consumption in these experiments. The results indicate an action of insulin in increasing the efficiency of oxidative phosphorylations and the possible participation of insulin in reactions involving the tricarboxylic acid cycle.

Relation of the adrenal cortex to the increased macrophagic activity induced by starvation
 ALBERT S. GORDON and GRACE F. KATSH (by invitation) *Dept of Biology, Washington Square*

College of Arts and Science, New York Univ, New York City It has been reported (Gordon and Katsh, *Federation Proc* 7 42, 1948) that chronic inanition results in an increased phagocytic response of the macrophagic system towards colloidal substances, particularly thorium dioxide Experiments were designed to test the possibility that this starvation effect is mediated through the adrenal cortex Thirty male rats (150-200 gm) were subjected to chronic inanition (5 gm ration daily) for 25-30 days A body weight loss averaging 31% was experienced at the end of this time Of these 30 animals, 18 were adrenalectomized and 12 served as controls Each of 8 of the adrenalectomized animals was injected with a total of 20 cc of aqueous adrenal cortical extract (Upjohn) and 1 cc of lipoadrenal extract (Upjohn), distributed over a 3-day period before, and 30 hr after adrenal removal The other 10 adrenalectomized rats were injected with 21 cc of 1% saline, spaced in the same manner as above The 18 adrenalectomized animals (used 1 day after the operation), the 12 unoperated starved and 10 normal fed rats were injected intravenously with 0.3 cc thorotrast and killed approximately 20 hr later Mean values \pm standard errors for ThO_2 per gm dried spleen were 1) fed untreated, 58.2 ± 7.8 mg, 2) starved untreated, 175.5 ± 11.3 mg, 3) starved adrenalectomized given saline, 70.6 ± 7.1 mg, 4) starved adrenalectomized given adrenal cortical extract, 123.5 ± 13.4 mg

Histological studies of the spleens revealed that the increased numbers and marked activity of the macrophages, characteristic of the starved rat, were diminished by adrenalectomy and that adrenal cortical hormone, but not saline, was greatly effective in preventing this impaired condition in the adrenalectomized animal

Effect of insulin on the rate of oxygen consumption by frog muscle DESMOND R. H. GOURLEY (by invitation) and KENNETH C. FISHER *University of Toronto, Toronto, Canada* In the presence of citrate, succinate and acetate, insulin causes an increase in the rate of oxygen consumption by isolated intact frog muscle The effect of the citrate, succinate, and acetate appears to be correlated with the ability of these compounds to produce spontaneous contractions in the muscle

Experimental observations on neural mechanisms involved in itching DAVID T. GRAHAM and HELEN GOODELL (introduced by HAROLD G. WOLFF) *New York Hospital and the Depts of Neurology and Psychiatry, Cornell Univ Medical College, New York City* Itching was produced by application of cowhage to skin Two components could be distinguished in the resulting itch a superficial pricking and a deeper burning sensation Ischemia of the forearm, causing loss of pricking pain but

not of deep burning pain, abolished the superficial pricking component, but not the deeper burning component Procaine block of a cutaneous nerve, resulting in the abolition of burning pain from pin prick with retention of pricking pain in an area of incomplete anesthesia, prevented development of burning itch, but allowed pricking itch to develop It is suggested that the two qualities of itch are mediated respectively by the rapidly and slowly conducting pain fibers from the skin Pin pricks in an itching area, or in areas adjacent to it, or in the same dermatome as the itching area, even at a distance of 30 cm, abolished itching for 20 to 60 seconds In a zone of secondary hyperalgesia (developing after faradic stimulation over a cutaneous nerve), cowhage induced either pain or no sensation, but not itch The evidence cited above indicates that to understand the neural mechanisms of itching it is necessary to consider not only peripheral phenomena, but also processes in the central nervous system, presumably in the cord

Early stages of gastric surface epithelization RHODA GRANT (introduced by A. C. Ivy) *Dept of Clinical Science, Univ of Illinois College of Medicine, Chicago, Ill* Gastric surface epithelization uncomplicated by concurrent regeneration of glandular epithelium has been studied histologically (1-8) hr after a) mild irritants have removed the surface cells, b) minute superficial cuts Irritants were used 1) in cats with gastric fistula under acute conditions, or were fed 2) to cats by tube, and 3) to rats by tube Control cuts were biopsied immediately after infliction and compared with cuts allowed to heal for varying intervals up to 8 hr Serial sections were stained with hematoxylin and eosin or Mayer's mucicarmine

In the early stages of surface regeneration, the cells which restore the surface continuity in denuded areas include parietal cells These are most numerous in the walls of crypts reforming at the surface level, but occasionally may be seen on the free surfaces between regenerating crypts and in new surfaces forming in cuts at or below midgland level The majority of cells in the new surfaces stain faintly for mucus and may be from the bases of crypts not completely removed by the irritant, and/or mucous neck cells Evidence points, as in former experiments, to restoration of surface continuity and of the essential surface topography before proliferation replaces cells shifted to the surface

Effect of ethyl carbamate on temperature regulation RONALD GRANT and MARILYN E. ROBBINS (introduced by VICTOR E. HALL) *Dept of Physiology, Stanford Univ, Stanford University, Calif* Magoun (*Proc Soc Exp Biol Med* 37 711, 1938) showed that polypneic panting occurs at normal

or subnormal body temperatures in some cats anesthetized with urethane. We have investigated the possibility that urethane promotes heat loss by an action on the thermoregulatory centers. Rabbits anesthetized with urethane (1.0 to 1.5 gm/kg in 20% solution intraperitoneally) show a rapid drop of body temperature due to 1) decreased heat production, 2) vasodilation in the ears, 3) in a few cases, polypnea. After body temperature has fallen 1 to 3°C polypnea ceases, vasoconstriction occurs and the fall of temperature is retarded. Shivering may occur. Warming restores the vasodilation and incites polypnea usually at subnormal rectal temperatures. Despite this evidence that urethane lowers the temperature thresholds for activation of thermoregulatory mechanisms we have concluded that its action is probably not upon the primary centers of thermoregulation for the following reasons: 1) whereas vasodilation and polypnea are practically coincident in normal animals urethane usually slows respiration (rather than causing polypnea), while inciting vasodilation, and thresholds for activation are widely separate in warmed animals, 2) intravenous or subcutaneous injection rarely causes vasodilation or polypnea, 3) inhibition of heat loss mechanisms by bacterial pyrogens is unaffected by previous or subsequent intravenous injection of urethane, intraperitoneal injection may reverse the inhibition of vasodilation without affecting inhibition of polypnea.

Influence of repeated artificial pneumothorax on hematocrit values and plasma volume. WILSON C. GRANT (introduced by WALTER S. ROOT) *Dept of Physiology, College of Physicians and Surgeons, Columbia Univ., New York City*. Pneumothorax was maintained for 20 to 80 days in 10 unanesthetized dogs, 3 of which were splenectomized. One hundred to 500 cc of air were injected at intervals of from 2 to 5 days. The volume of the refill was always adjusted to maintain the desired elevated intrathoracic pressure (-2 mm Hg to +2 mm Hg). Pneumothorax was moderate and the animals remained in good condition. Measurements were made on jugular venous blood during a 2- to 3-weeks control period and at 2- to 3-day intervals in the pneumothorax period, at least 2 days following an insufflation. Hematocrit and O₂ capacity values increased 10 to 30% in 6 to 20 days. Plasma volume (T-1824) decreased 6 to 28% while the refractive index of plasma rose slightly. No significant increase in reticulocyte percentage was observed. Approximately the same response was observed in the splenectomized dogs. Blood values returned to those of control level within 1 to 2 weeks after cessation of pneumothorax. Anoxic anoxia was not an important factor, since normal values for arterial O₂ saturation were obtained in

18 out of 20 measurements on 5 dogs during the pneumothorax period. The animals responded to partial collapse by an increased pulmonary ventilation. The response of the blood to repeated pneumothorax is, therefore, a relative polycythemia which can be partially explained by plasma loss. No clear evidence of increased erythropoiesis was found. Hemoglobin production following pneumothorax is being studied by the Whipple-Robbscheit-Robbins technique on the chronically anemic dog.

Non-dependence of tubular sodium reabsorption upon glomerular function. D. M. GREEN and ALFRED FARAH (by invitation) *Depts of Medicine and Pharmacology, Univ of Washington, Seattle, Wash.* The amount of sodium reabsorbed by the tubular apparatus has been considered to represent a constant fraction of the amount filtered (Mokotoff *et al* (*Journal Clin Invest* 27 1, 1948)). Such a hypothesis would make the excretion of sodium primarily dependent upon glomerular function. However, the ability of many patients to maintain sodium balance despite markedly impaired filtration rates would appear more consistent with the supposition that the percentage of filtered sodium rejected by the tubular apparatus could be regulated independently of the filtration function. Evidence for the existence of such an independent regulation has been secured by measuring the percentage of filtered sodium excreted under different conditions of sodium load. Solutions of sodium chloride varying in concentration from 0.86 to 30% were infused into dogs at rates of 1 to 9 cc/min. Under such circumstances the test animals were found capable of increasing sodium excretion several 100-fold, to values which represented as much as 40% of the quantity of sodium filtered. These changes were not accompanied by consistent or proportionate alterations in glomerular filtration rate or renal plasma flow. Calculations based on the clearance data indicated that the rise in sodium excretion was due almost entirely to a decrease in the percentage of its tubular reabsorption.

Effects of adrenal resection on hypertension and diabetes. D. M. GREEN, J. N. NELSON (by invitation) and G. A. DODDS *Dept of Medicine, Univ of Washington School of Medicine, Seattle, Wash.* Bilateral adrenal resection was performed on a 29-year-old female suffering from hypertension and diabetes. Diabetes had been present since age 6. Daily insulin requirements were 70 to 85 u. Hospitalization for diabetic complications had occupied almost one quarter of the last 3 years. Hypertension, first recognized 8 years previously, had become severe and progressive. Transitory episodes of encephalopathy and myocardial failure characterized the last year. Preoperative blood

pressure averaged 260 mm Hg systolic, 140 mm diastolic. The heart was enlarged on X-ray. Renal function was approximately 40% of normal. Grade-4 retinitis was present. At operation, performed in 2 stages, not less than 98% of all adrenal tissue was removed. The immediate postoperative period was marked by paralytic ileus and transitory myocardial failure. Later complications included marked weakness, intermittent vomiting and one episode of frank crisis. The patient became ambulant during the 2nd week and was discharged on the 22nd postoperative day. Blood pressure fell to 110 mm Hg systolic, 80 mm diastolic 4 hr postoperatively. Elevated pressures were subsequently observed only during brief periods of desoxycorticosterone overdosage. X-ray 3 weeks postoperatively showed normal heart size. Cortical extract requirements initially exceeded 200 cc/day but decreased progressively during convalescence. Insulin needs roughly paralleled cortical extract dosage. Six weeks postoperatively the blood pressure was normal, the daily extract requirement was 15 cc and the insulin requirement 25 U.

Variation of choline acetylase content of brain in stressed and unstressed normal and adrenalectomized rats. RUVEN GREENBERG (introduced by F. A. HARTMAN) *Dept. of Physiology, Ohio State Univ., Columbus, Ohio*. In adrenal cortical insufficiency there is a generalized weakness whose mechanism is unclear. The nerve tissue conduction and maintenance is in some way involved. The choline acetylase content of acetone-dried brain powders made of pooled rat brains was measured by the rate at which the powders acetylated choline to form acetylcholine (method of Nachmansohn and Machado, 1943). The acetylations by brain extracts of adrenalectomized animals, stressed and unstressed, compared to sham-operated animals treated in the same way gave variable values in all the groups tested. The range of values between the adrenalectomized and sham groups and the stressed and unstressed groups overlapped. The effect of coenzyme (Lipmann, 1945) added to the acetylation substrate made for about 100% increase in synthesis. This increase did not vary significantly between the different preparations. The effect of adrenalectomy and stress, individually or combined, on brain tissue does not consistently change either the choline acetylase or coenzyme levels. These act on another part of the acetylcholine mechanism or on other mechanisms entirely.

Comparison of effects of a new ganglionic blocking agent and a new sympatholytic. K. S. GRIMSON and J. R. CHITTRUM (by invitation) and F. H. LOVINCIO *Dept. of Surgery, Duke University, Durham, N. C.* Similar studies have been performed testing 2,6 dimethyl diethyl piperidinium

Bromide (S. C. 1950) and 2-(N,p-tolyl-N-(m'-oxyphenyl)-aminomethyl)-imidazoline hydrochloride (C. 7337) in dogs and patients. In dogs effective doses of 1950 ranged from 5 to 10 mg/kg and of 7337 from 0.2 to 0.5 mg/kg. These amounts reduced blood pressures, prevented increase of pressure with occlusion of carotid arteries, prevented increase of blood pressure with anoxia, and reduced or blocked increase of blood pressure normally following stimulation of the central end of a divided vagus nerve. Pituitrin increased blood pressure after effective doses of either drug. Differences between the two drugs were apparent in other tests. Pulse rate decreased or did not change with 1950 and increased temporarily with 7337. Increase of blood pressure following adrenalin was accentuated after 1950 and blocked after 7337. With 1950 an increase of blood pressure occurred one or two minutes after discontinuing anoxia. This did not occur after 7337. Prostigmin following 1950 elevated blood pressure and restored responsiveness to vasomotor reflexes, but not following 7337. Chronic neurogenic hypertension in dogs was reduced by either drug. Increase of blood pressure with increased intracranial pressure was not prevented by effective doses of 1950, but was reduced or prevented by large doses of 7337. One to two mg/kg of either 1950 or 7337 injected intravenously in patients or 1 to 2 mg/kg of 7337 orally usually blocked increases of blood pressure with breath holding or with one hand in ice water, and warmed extremities. Results of additional clinical studies demonstrating differences of effects in patients will be presented.

Effect of spinal cord transection on blood acid-base balance during exercise. FRED S. GRODINS and DONALD P. MORGAN (by invitation) *Dept. of Physiology, Northwestern Univ. Medical School, Chicago, Ill.* Blood acid-base balance was studied in barbitalized dogs during electrically induced exercise of the hind limbs before and after section of the spinal cord at T10. The total CO_2 content and pH of arterial plasma were determined at rest and during a steady state of exercise, and the corresponding CO_2 tensions calculated from the Henderson-Hasselbalch equation. Percutaneous electrical stimulation with 60-cycle AC modulated at 100/min was used to produce oxygen consumptions of 2-7 times the resting value. In 11 experiments on 8 dogs, there was an average fall of 1.77 mm Hg in arterial pCO_2 during a steady state of exercise compared to the resting value. This mean difference was not significantly different from zero ($t = 1.65$, $P > 10\%$). In 14 experiments in 6 dogs after cord section, there was a mean increase of 3.94 mm Hg in arterial pCO_2 during a steady state of exercise which was highly significant ($t = 4.59$, $P < 1\%$). Oxygen consumptions during exercise

varied from 2.2 to 5.5 times the resting level in both groups. Plots of the acid-base pathways revealed essentially no change in the intact group for oxygen consumptions up to 2.5 times resting. Above this level, a metabolic acidosis pathway was followed. The sectioned group followed a pathway corresponding to a respiratory acidosis with a metabolic acidosis superimposed.

Distribution of microgram amounts of labeled thyroxine in the rat J. GROSS and C. P. LEBLOND (introduced by S. M. FRIEDMAN) *Dept of Anatomy, McGill Univ, Montreal, Canada*. Microgram amounts of labeled thyroxine were prepared by iodinating DL-diiodothyronine on a micro-scale or by extracting thyroxine from the plasma of rats previously given radio-iodine. The purity of the material was checked by isotope dilution. The distribution studies at 2, 24 and 72 hours after injection emphasized the predominant role of the liver in storing thyroxine and excreting it into the bile. Thyroxine is then mostly eliminated in the feces. In addition, large amounts are present in muscle and skin. These conclusions probably apply to the normal thyroid hormone because it was possible to demonstrate the presence of a thyroxine-like compound in thyroid tissue, plasma, liver and muscle under normal conditions.

Mucoproteins of gastric juice and mucus and the mechanism of their secretion ALLAN GROSSBERG (by invitation), S. A. KOMAROV and HARRY SHAY *Samuel S. Fels Research Inst, Temple Univ School of Medicine, Philadelphia, Pa*. Evidence has been obtained in support of earlier observations (Webster and Komarov, *J Biol Chem* 96:133, 1932) that at least two different mucoproteins are secreted by the gastric mucosa in the dog. One of the mucoproteins is characterized by the presence of both hexuronic acid and hexosamine, apparently in the proportions found in mucotin, sulfuric acid, and it is present both in alkaline mucus and in acid gastric juice; the second mucoprotein has hexosamine in its molecule but a much smaller proportion of hexuronic acid, if any at all. The prosthetic group of this latter mucoprotein may be identical with the 'neutral polysaccharide' described by Meyer, Smyth and Palmer (*J Biol Chem* 119:73, 1937). This mucoprotein is particularly characteristic of the alkaline mucus although it is also present in solution in acid gastric juice. Data were obtained on gastric secretions from dogs 1) in the resting state, 2) prior and subsequent to sham-feeding and 3) prior and subsequent to the injection of histamine. The analytical results indicate that 1) the secretion of the two mucoproteins is stimulated by sham-feeding but to different degrees, suggesting some difference in the secretory mechanisms involved, 2) the secretion of the two mucoproteins does not parallel that

of either pepsin or acid, 3) the effect on secretion with increased nervous stimulation is greatest for pepsin and the least for the hexuronic acid-free mucoprotein, with an intermediate effect for the other mucoprotein, 4) histamine does not stimulate the secretion of either mucoprotein.

Experimental production of hemorrhages in dogs with the use of aminopterin and their control with toluidine blue BURTON J. GROSSMAN, MARGARET H. SANDERSON, and WILLADENE EGNER (introduced by J. Garrott Allen) *Dept of Surgery, Univ of Chicago, Chicago, Ill*. The incidence of hemorrhage in patients with acute leukemia appears to be increased during the early period of aminopterin (4-aminopteroyl glutamic acid) therapy. The bleeding tendency is not present when the patient is in complete remission. Studies of the effect of aminopterin on the clotting mechanism in the normal dog were undertaken. These included the whole blood clotting time, prothrombin time, platelet count, observation for lysis of clot, the amount of protamine required to allow standard heparinized samples to clot and gross observations for the absence or presence of bleeding. Ten dogs, weighing 8 to 10 kg, were given a daily dose of 0.5 mg of aminopterin. Bleeding from the mouth and gastrointestinal tract occurred in all animals between the 8th and 11th day. At this time the platelet count was rarely below 150,000. The clotting times were normal or slightly prolonged. The prothrombin activity was unchanged except just before death. Increased lysis was not observed. The protamine requirement of standard heparinized blood was increased and this increase was out of proportion to the slight increase in the whole blood clotting time. Aminopterin was discontinued in 2 dogs and bleeding stopped after 4 days. Two dogs were given a single intravenous dose of toluidine blue (5.0 mg/kg of body weight) and bleeding stopped within 6 hr. Six dogs were continued on aminopterin and bleeding was controlled with a single injection of toluidine blue. The protamine requirement returned to normal. These animals died within 3 days without external evidence of hemorrhage, although 2 showed a hemorrhagic gastritis.

Clinical and physiological studies on thiomerin—a subcutaneously injectable mercurial diuretic J. GROSSMAN (by invitation), R. E. WESTON, I. S. EDELMAN (by invitation) and L. LEITER (by invitation) *Medical Division, Montefiore Hospital, New York City*. Approximately 200 subcutaneous injections of Thiomerin (Di-sodium-N-(γ -carboxymethylmercaptomercuri- β -methoxy) propyl camphoramate) in more than 40 patients produced changes in body weight and daily urinary volume and chloride excretion comparable to those following the injections of Mercuzanthin and Mercu-

hydrin. No systemic reaction or unusual local discomfort was observed. Only two reactions occurred at the site of injection, one consisted of ecchymosis in a patient with a bleeding diathesis and the other, of necrosis and sloughing of skin when Thiomerin was administered into an area of dependent edema. Both patients tolerated subsequent injections without ill-effect. In addition, simultaneous renal clearances of mannitol, PAH, sodium, chloride and uric acid, prior to and following intravenous Thiomerin or Mercuzanthin administration were determined. Except for the transient renal hemodynamic response to the Theophylline fraction of the Mercuzanthin, no significant differences between the diuretic effects of the two drugs were noted. In collateral studies on other tubular functions, both mercurials were found to have qualitatively and quantitatively similar depressive actions (i.e. decreased glucose T_x and renal PAH extraction). A comparison between the effects of intravenous and subcutaneous administration of Thiomerin in the same patients revealed no significant differences except in the time of response.

Action of neurohumoral agents in the human skin. M. I. GROSSMAN, HENRY D. JANOWITZ (by invitation) and R. R. SONNENSCHN (by invitation). *Dept. of Clinical Science, Univ. of Ill. College of Medicine, Chicago, Ill.* Physiological activities known to be mediated by neurohumoral agents are sweating by acetylcholine, piloerection by sympathin, and constriction of small blood vessels by sympathin. Intradermal injection of neurohumoral agents, in addition to stimulation of the effector organs just listed, stimulates certain nerve endings. These include a) sensory nerve endings for pain and itch which respond to histamine, b) motor nerves to the sweat glands and piloerector muscles which respond to acetylcholine and to nicotine, and c) certain dorsal root ramifying systems of nerves involved in vasodilation, hyperalgesia and itchy skin, all subject to stimulation by histamine. The effects under b) and c) can be classified as axon reflexes and the drugs listed with them are capable of initiating the reflex. The neurohumoral effector agent of these axon reflexes is known in the case of b) but not of c). The nicotinic effects can be blocked by tetraethylammonium (TEA). TEA also blocks the initiation of the axon reflex itchy skin surrounding a histamine wheal but it does not interfere with the local sensation of spontaneous itch. Pontocaine causes local anesthesia concomitantly with surrounding flare and hyperalgesia, suggesting that it selectively anesthetizes pain nerve endings but stimulates, directly or indirectly, nerves concerned in establishment of hyperalgesia and flare. The results with TEA in itchy skin and pontocaine in hyperalgesia

each demonstrates dissociation between the local primary sensation and the altered state of sensibility surrounding the injection site, thus supporting the hypothesis that the nerve fibers responsible for the altered state are not the same ones which convey the impulses for the spontaneous sensation.

Pressure changes in the pulmonary artery and aorta before and after ligation of the patent ductus arteriosus. ROBERT F. GROVER (by invitation), HENRY SWAN II (by invitation) and CLARENCE A. MAASKE. *Depts. of Physiology and Pharmacology, and of Surgery, Univ. of Colorado Medical Center, Denver, Colo.* Measurements of pulmonary artery and aortic blood pressures by puncture of the vessel at operation were made by means of resistance type strain gauges in 7 patients just before and after ligation of patent ductus arteriosus. Cardiac catheterization was employed in some of these patients and comparisons between pulmonary arterial blood pressure before and after opening the thorax were made. Immediately following ligation of the patent ductus arteriosus, the mean pulmonary artery pressure fell an average of 11 mm Hg for all patients. Excepting one patient, pulmonary artery pulse pressure was unchanged or only slightly increased. Following ligation of the duct, mean aortic pressure rose an average of 9.5 mm Hg, with an associated decrease in pulse pressure and an elevation of diastolic pressure. The contours of the pulse waves obtained while the ductus was patent were distorted in both the pulmonary artery and the aorta, probably resulting from pressure irregularities accompanying the abnormal blood flow. Ligation of the ductus generally gave pulse waves which approached the normal by reduction of these distortions. Good correlation was seen between the pulmonary artery pressures obtained by catheterization with the chest closed and those obtained by needle puncture with the chest open. More extensive comparisons of the normal pressures under these two conditions have been conducted on dogs.

Excitability changes in dorsal roots produced by electrotonic effects from adjacent afferent activity. HARRY GRUNDFEST and JONATHAN MAGNES (by invitation). *Dept. of Neurology, College of Physicians & Surgeons, Columbia Univ., New York City.* Electrical activity produced in the spinal cord of cats by stimulating a dorsal root induces electrotonic potentials in an adjacent, inactive root. According to Lloyd and McIntyre (*Federation Proc.* 7: 74, 1948), the first three phases, beginning negatively, are referable to the intramedullary afferent volley. Following, and overlapped by the terminating negative cord potential, they found a positive phase which is "an electrotonic extension of the potential of terminating collaterals" of the active root, with 3 msec

"half-life" This sequence of electrotonic potentials in the inactive root should cause modifications of excitability Stimulating electrodes on a root, close to the cord, tested the temporal changes of excitability during cord activity produced by conditioning stimulation of another root (cats, nembutal anaesthesia) Excitability was heightened during the first half msec after the conditioning volley Depression followed, lasting about 3 msec (maximum between 1.5 and 2.5 msec) Though of shorter duration, this depression is consonant with the existence of the positive electrotonic phase of Lloyd and McIntyre, and further demonstrates its reality The briefer duration may be ascribed to the rapid decay of the magnitude of the electrotonic potential in the extramedullary root These excitability changes have been observed in approximately 50% of the root pairs tested Variability is to be expected since the effect depends upon appropriate spatial relations between the intramedullary terminations of active and inactive fibers

Action of antitrypsin and antifibrinolysin on the first phase of the blood clotting reaction M MASON GUEST and THOMAS E NELSON (by invitation) *Dept of Physiology and Pharmacology, Wayne Univ College of Medicine, Detroit, Mich* The proteolytic enzyme, trypsin, is inactivated by either soy bean trypsin inhibitor or beef plasma antifibrinolysin (antiplasmin) Similarly, fibrinolysin (plasmin) is inactivated by both trypsin inhibitor and antifibrinolysin However, it has been found that only one of these inhibitors modifies the first phase of the blood clotting reaction Soy bean antitrypsin (crystalline material prepared by M Kunitz or the E C Loomis preparation) inhibits the first stage of the clotting reaction but antifibrinolysin (E C Loomis preparation) has no demonstrable effect upon the rate or character of clot formation The failure of antifibrinolysin to alter the clotting reaction suggests that this substance is different from soy bean antitrypsin and that proteolytic activity involving fibrinolysin is not a part of the clotting mechanism Investigation of the mode of action of antitrypsin in inhibiting the first phase of the clotting reaction has failed to reveal whether this substance acts as an antithromboplastin, an antiprothrombin, an anti-accelerator globulin or whether it acts by blocking the reaction of these substances Unless an inhibitor of thrombin formation can be shown to react at a measurable rate with one of the essential components of the first phase of the clotting reaction, reducing the potency of this component as a participant in the thrombin formation reaction, it does not appear possible to determine the point of action of such an interfering substance with methods available at present

A chromogenic steroid occurring in the urine of

males after muscular exertion H S GUTERMAN and L M KRAUS (introduced by R Levine) *Dept of Metabolic and Endocrine Research, Medical Research Inst, Michael Reese Hospital, Chicago, Ill* In performing pregnandiol determinations on urine samples from normal adult males according to the method previously published from this laboratory (*J Lab & Clin Med* 33 356, 1948), we found unusually large amounts of 'pregnandiol' present in some of the specimens Study of the chromogen revealed that on extraction it is present in the neutral non-ketonic steroid fraction when separated with Girard's reagent T Precipitation with digitonin indicated that a β -hydroxyl group might be present in the 3 position Since the Zimmermann reaction produced no color with the material after digitonin precipitation, it is believed that the presence of ketonic groups in position 3, 17 and 20 can be ruled out Bromine water was decolorized by an alcoholic solution of the material, and thus the presence of at least one double bond was indicated Thinking that the product might be 5 β androstenediol (3 β -17 α), we applied Bostock's fluorescent test (*Nature* 162 577, 1948) The material under study gave a green-blue fluorescence instead of the violet shade emitted by crystalline androstenediol Further studies are being conducted to characterize this urinary excretion product To date, the chromogen has been found only in males It appears to be of significance physiologically since it occurs in the urine in rather large amounts following muscular exertion

Lipide studies on whole anterior lobe, nuclei, and cytoplasmic particulates of lamb pituitary glands M H HACK (introduced by HUBERT R CATCHPOLE) *Dept of Pathology, Univ of Illinois, College of Medicine, Chicago, Ill* Lyophilized whole anterior pituitary of lamb and isolated cell fractions were assayed for free and protein-bound phosphatides according to the procedure described earlier (*J Biol Chem* 169 137, 1947) All cell fractions were obtained from homogenates prepared by Claude's method The large granule fraction was clearly separable into a buff-colored upper layer (mitochondria) and a white lower layer (eosinophilic granules) The identity of all fractions was confirmed histologically A new "acetal" was shown, by means of fuchsin sulfurous acid, to be present in the lipides extracted from the intact tissue and from each of the cell fractions by acetone, chloroform-methanol (1:1), and by benzene Histochemical confirmation was effected by means of the same technique applied to frozen sections of fresh tissue Acetal phosphatide was barely detectable The distribution of lecithin, cephalin, and sphingomyelin, expressed in μ M/gm dry weight, and the relative concentration of "acetal" were

	LECITHIN	CEPHALIN	SPHINGOMYELIN	'ACT. TAL.'
Whole tissue	75	58	17	+
Mitochondria	117	87	46	++
Eosinophilic granules	62	54	29	+
Microsomes	162	156	40	++++
Nuclei	43	38	0	+

One-third to one half of both lecithin and cephalin were present as lipoprotein. The sphingomyelin was largely free except in the microsome fraction. As in the case of cell fractions of rat liver, each fraction is here shown to be distinct in its phosphatide composition.

Myocardial metabolism in thiamine-deficient dogs studied by intravenous catheterization of the coronary sinus. D. B. HACKEL, W. T. GOODALE, R. P. JOHNSON (introduced by W. FLEISCHMANN). *Physiology Section, Medical Division, Army Chemical Center, Md.* Studies of the myocardial utilization of lactate and pyruvate were made in intact normal dogs and in dogs with acute and chronic thiamine deficiency, using the technique developed by Goodale et al. (*Am J Physiol* 152:340, 1948) for catheterizing the coronary sinus. Mean arterial pyruvate levels of 1.71 ± 0.13 mg % with coronary A-V differences of 0.76 ± 0.1 mg %, and lactate levels of 12.2 ± 0.96 mg % with coronary A-V differences of 5.3 ± 0.5 mg % were obtained in a series of normal nembutalized dogs.

Thiamine deficiency was produced by feeding a diet of canned dog food which had been autoclaved at 15 lb pressure for 12 hours to destroy thiamine, and supplemented by other synthetic vitamins of the B complex as well as Vitamin C. Anorexia and weight loss began in about 3 weeks, going on to convulsions with opisthotonus in 6 weeks. Complete relief of symptoms was brought about by the intravenous administration of 2 mg of crystalline thiamine. Chronic thiamine deficiency was produced by supplementing the above diet with daily intramuscular injection of 50-100 γ of crystalline thiamine. Small additions to, or subtractions from, the daily dose of thiamine were reflected in prompt weight changes. Acute deficiency resulted in decreased pyruvate utilization by the heart, with arterial levels up to 5.9 mg %, and almost no lactate utilization, despite arterial levels up to 60 mg %. Determinations done in the course of chronic deficiency revealed an uptake by the heart of both lactate and pyruvate which was below the expected normal range.

Effects of shock (low arterial blood pressure) on the pulmonary vessel pressures. FRANCIS J. HADDY (by invitation), GILBERT S. CAMPBELL (by invitation) and M. B. VISSCHER. *Dept of Physiology, Univ of Minnesota, Minneapolis, Minn.* Studies have been made on 64 dogs anesthetized

with nembutal, 30 mg/kg, on pulmonary artery and venous pressures measured with a Statham strain-gauge attached to flexible catheters. The average mean pulmonary artery and venous blood pressure measured relative to the intrathoracic pressure in 57 animals with peripheral arterial blood pressures above 100 mm Hg was 17.8 and 8.5 mm Hg respectively. In 7 animals with blood pressures below 100 mm Hg the pressures were 14.0 and 2.3 mm Hg respectively. Separating the group of 57 animals into those with peripheral arterial blood pressures between 100 and 150 mm Hg and those with pressures above 150 mm Hg one finds the pulmonary arterial and venous pressures in the former 40 animals to be 16.7 and 7.6 mm Hg respectively and in the latter 17 animals to be 18.5 and 9.7 mm Hg respectively. From these data there appears to be a positive correlation between the peripheral arterial blood pressure and the pulmonary pressures. From the same group of animals there was found to be no significant difference in the pulmonary pressures in males or females. When broken down into animals with body weights below 20 kg and those above 20 kg, there was noted no significant difference in pulmonary arterial or venous pressures in relation to weight. It is likely that a decreased cardiac output in shock is at least partly responsible for the observed effects.

Light flux constancy at the intensity lumin of the eye for total receptor cross-sectional areas. CHARLES HAIG. *Dept of Physiology and Biochemistry, New York Medical College, New York, N. Y.* By methods previously described (*Federation Proc* 7:47, 1948) it has been demonstrated that for homogeneous rod populations, i.e., for specific retinal regions, the product of the threshold intensity I and the retinal (stimulus) area A is constant for areas ranging from 0.04 degree subtense to 1.0 degree subtense. For homogeneous cone populations IA is constant for areas up to 0.5 degree subtense. Calculations have been made for a single eye to determine whether the luminous flux is constant for rod and cone cross-sectional areas in non-homogeneous retinal regions, e.g., the fovea as compared with peripheral regions. The data of Østerberg (1935) and Polyak (1941) on rod and cone diameters and population densities in various retinal regions provide the means for computing A in terms of total rod or cone cross sectional area in a given retinal (stimulus) area. For rods it is found that IA so computed is constant from 2 degrees out to 6 degrees from the foveal center. From 10 out to 18 degrees IA is again constant at twice the value found closer to the center. For the inner cone segments it is found that IA is constant from the foveal center out to 10 degrees in the periphery, beyond which it rises to a value twice as great at 18 degrees in the periphery. These calculations for

one eye indicate that measurements on several eyes will reveal that the luminous flux actually incident upon the receptor elements is constant for the entire central area

Oxygen consumption of liver slices from febrile and normal rabbits V E HALL, J FISHGOLD (by invitation) and R GRANT (by invitation) *Dept of Physiology, Stanford Univ, Stanford, Calif* Observations published in the literature suggest that during the early stage of fever the temperature in or near the liver rises earlier and in greater degree than the rectal temperature This has been interpreted as showing that an increase in liver metabolism contributes significantly to the febrile temperature rise However, measurement *in vitro* of the O_2 consumption of liver slices taken from rabbits 15 minutes after the injection of typhoid-paratyphoid vaccine (a time when the liver temperature was said to have been rising) yielded a mean Q_{O_2} value of 3.71 as compared with a mean of 4.32 for untreated controls The difference is statistically significant and shows that the liver metabolism under the conditions employed is depressed in tissue taken from febrile animals If the heat production of the liver is increased early in the fever produced by bacterial pyrogen, it is attributable to factors inoperative when the liver metabolism is studied *in vitro*

Studies of a case of congenital heart disease with cyanotic episodes W F HAMILTON, J A WINSLOW (by invitation) and W F HAMILTON, JR (by invitation) *Depts of Physiology, Medicine and Roentgenology, Univ of Georgia School of Medicine, Augusta, Ga* The patient, an 18-year-old girl had been through grammar school and was in fair health though she had been subject to spells of cyanosis and fainting Clinical impression was Tetralogy of Fallot During two cardiac catheterizations she became intensely cyanotic and irrational but not unconscious Pressures in vein and auricle were normal Rt ventricle 100/0, Aorta 65/30, Femoral 85/40, Pul art 5/0 These data confirm patency of the interventricular septum and pulmonary stenosis Blood in right ventricle, pulmonary artery and femoral artery were 10-20% saturated with A-V difference between 0 and 1% Oxygen consumption varied around 200 cc/min though for 2 minutes it apparently ceased When not cyanotic O_2 consumption was steady at 150 cc/min with blood pressure 140/80 and arterial O_2 saturation of 70-80% Cardiac index at this time was 2.04 L and circulation time 14 sec by dye injection method Cyanotic episodes resulted from activity, emotion, or vasodilator drugs and were accompanied by lowered arterial pressure, oxygen saturation, and O_2 uptake

Various explanations may be considered The favored one is that the functionally single ventricle

pushes blood out into the two circulations as governed by their respective resistances In this case the pulmonary resistance seems to be very high and a lowering of the systemic resistance causes increasing amounts of the ventricular output to pass out of the aorta and less or even no blood to perfuse the lungs This caused temporary reduction or even cessation of oxygen uptake and varying degrees of arterial unsaturation

Measurement of cardiac volume in the dog from X-ray shadow area W F HAMILTON, JR (by invitation) and PHILIP DOW *Depts of Physiology and Roentgenology, Univ of Georgia School of Medicine, Augusta, Ga* An effort has been made to standardize a cardiac-volume method for use during experiments on circulatory dynamics After sacrifice experiments, P-A roentgenograms were taken of the closed chests of 53 supine dogs The chests were opened immediately, the great vessels were tied off, and actual cardiac volumes were measured by immersion These volumes were compared with the areas of corresponding shadows on the films (corrected for tube distance)

No formula found for dog or human hearts approximated the relationships obtained, so a new formula was empirically derived The best fit was given by an equation of the form $Vol = a \left[\left(\frac{s}{l} \right)^{\frac{1}{b}} \times area \right]^b$, in which s is the shorter and l the longer dimension of the shadow Parallel projection of a prolate spheroid should give $a = 0.75$ and $b = 1.5$ The oversimplifications in this hypothesis are indicated by the empirical results $a = 0.4$ and $b = 1.7$ This formula predicts the volume of dog hearts larger than 100 cc with an average error of 5% (maximum 13%) Predictions for smaller hearts are consistently too high or too low (average error 22%) Most of these, however, were from puppies and do not fall in the range of animals ordinarily used in the experiments Supplementary projections were not employed to increase accuracy, since such would not be feasible during experiments for which the method is devised

Effects of di-isopropyl fluorophosphate (DFP) on electroencephalogram and cholinesterase activity J L HAMPSON (by invitation), C F ESSIG (by invitation), ALICE WILLIS (by invitation), and H E HIMWICH *Medical Division, Army Chemical Center, Md* Di-isopropyl fluorophosphate (DFP) was injected into one common carotid artery of curarized rabbits receiving artificial respiration A needle electrode was inserted through the skull over each cerebral hemisphere The electroencephalographic changes were observed with the Grass apparatus and cholinesterase activities of various parts of the brain were subsequently determined by the method of Michel

The cerebral parts included the cortex, midbrain, medulla and cerebellum. The electroencephalographic changes were placed in five categories of increasing severity: 1) No permanent change from the control; 2) Early permanent, alterations including slight increases in regularity, amplitude and rate; 3) Intermediate, phase 1, marked changes limited however chiefly to the right hemisphere; 4) Intermediate, phase 2, marked changes (short of grand mal) appearing in both cerebral hemispheres; 5) Continued grand mal-like activity on both sides.

In general, with succeeding categories, cholinesterase activity decreased more profoundly until the fourth category was obtained. Statistical analyses of cholinesterase activities revealed however no differences between no permanent and early permanent. But between early permanent and intermediate phase 1 all differences were significant while between intermediate phase 2 and grand mal no significant differences were noted. Though a rough correlation between cholinesterase activities and abnormalities of the electroencephalogram was observed the extent of the fall in the cholinesterase activity is not sufficient to explain the degree of the abnormality in the electroencephalogram.

Hemoglobin iron as a stimulus for the production of ferritin. JOHN K. HAMPTON, JR. (introduced by H. S. MAYERSON) *Dept. of Physiology, School of Medicine Tulane Univ., New Orleans, La.* Studies by Granick and others have shown that iron is stored chiefly in the liver, spleen and bone marrow as the protein-iron compound, ferritin. Evidence is also available to indicate the presence of ferritin in crystallizable amounts in the kidneys of the cat, dog, and human. Its presence in horse kidney has been demonstrated in minute amounts. The present experiments extend these findings to the mouse and rabbit kidney. It has proved difficult to crystallize ferritin from the kidney by the usual CdSO_4 method from animals on the usual laboratory regime or after minimal doses of hemoglobin. However, when increasing amounts of hemoglobin are injected intraperitoneally, correspondingly larger amounts of ferritin appear in the mouse and rabbit kidneys. With optimal doses of hemoglobin iron, all animals show the presence of ferritin in their kidneys. More ferritin is found in the liver than in the kidney when small doses of Hb are used, but when larger (and optimal) doses are used, the amounts of ferritin in the liver and kidney tend to be similar. Experiments in progress are designed to investigate these relationships in the human kidney.

Effect of stimulation of sympathetic nerves on capillary filtration. ESTHER HARDENBERGH and JAMES V. MALONEY, JR. (introduced by WILLIAM

H. FORBES) *Dept. of Physiology, Harvard School of Public Health, Boston, Mass.* Variations in lymph flow and composition have been used in studying the effects of stimulation of sympathetic nerves on capillary filtration in the head and hind limb regions of the dog. After cannulation of the regional lymphatic vessels, control collections were made during standardized passive movement of the part. The effectiveness of sympathetic nerve stimulation was indicated by skin temperature changes. The quantity of lymph was increased 50-100% over control values during stimulation, while the protein concentration was somewhat reduced. In the hind paw most of the increase occurred in the first 10 minutes of stimulation. Such an increase appears surprising since the filtration pressure should be decreased by the intense precapillary vasoconstriction produced by the stimulation. Several explanations have been considered: 1) a lymph reservoir which is somehow 'squeezed out' is rendered unlikely by the fact that there is no post-stimulation decrease in flow; 2) increased post-capillary resistance is rendered unlikely by the fact that lymph flow is increased even when capillary pressures have already been raised by venous obstruction; 3) gross changes in capillary bed due to closing of arterio-venous anastomoses does not affect the result, since the increase in lymph flow occurs when the paw is immersed in a water bath at 15 degrees Centigrade. There appears to be an increase in capillary filtration during stimulation of sympathetic nerves, but the exact mechanism is not established.

Renal excretion of creatinine in man. KENDRICK HARE, HAROLD GOLDSTEIN (by invitation), HENRY L. BARNETT (by invitation), HELEN McNAMARA (by invitation), and RUTH S. HARE (by invitation) *Dept. of Pediatrics, The New York Hospital and Cornell Univ. Medical College, New York City.* Using the adsorption-elution method of Hare and Hare for creatinine determinations, we have compared the renal plasma clearance of endogenous creatinine with simultaneous inulin clearances in 24 observations on 22 normal subjects ranging from 1 week to 40 years of age. Each observation included 3-9 clearance periods of 10-20 minutes duration. The average creatinine/inulin clearance ratio was 1.03 with a range of 0.82-1.26. The clearance of exogenous creatinine, given by mouth or by vein, was similarly studied in 9 experiments on 6 normal subjects for a total of 76 periods. The average creatinine/inulin clearance ratio was 1.08 with a range of 0.97-1.20. In chronic renal insufficiency the clearance of both endogenous and exogenous creatinine is elevated above the inulin clearance to give creatinine/inulin clearance ratios of 1.29-2.64.

Determination of creatinine in blood and urine

RUTH S HARE (by invitation) and Kendrick Hare *Dept of Pediatrics, The New York Hospital and Cornell Univ Medical College, New York City* Pure creatinine solutions of 0.05-0.40 mg % develop maximal color with alkaline picrate within 20 minutes and remain stable, tungstic, picric, trichloroacetic acid or cadmium, zinc or iron filtrates of serum or plasma continue to develop color, as measured at 500 μ in a Beckman spectrophotometer, for 2 hours or more. The interference of the non-creatinine chromogens can be avoided by adsorbing the creatinine on Lloyd's reagent and eluting with alkaline picrate solution (Borsook, *J Biol Chem* 110:481, 1935). This procedure gives 98-101% recovery of creatinine added to serum or urine, synthetic creatinine, containing radioactive carbon, is completely adsorbed by Lloyd's reagent from urine and from plasma filtrates. Approximately 80% of the material in normal human serum giving the Jaffe reaction is creatinine, 90-100% of the urinary chromogen is creatinine. The serum creatinine falls from 0.8 mg % in the first week of life to 0.3 mg % at one month, begins to rise at two years and reaches the adult level of 0.8 mg % at 15-18 years. In chronic renal insufficiency, the serum creatinine constitutes 90% or more of the total chromogen.

Effects of lanatoside C upon ectopic ventricular

activity following coronary occlusion A SIDNEY HARRIS and ROBERT H KOKERNOT (by invitation) *Baylor Univ College of Medicine, Houston, Texas* The threshold intravenous dose of lanatoside C for the production of ventricular ectopic discharges in unoperated dogs anesthetized with morphine and light barbitol sodium was found to be about 0.125 mg/kg when administered in two equal parts separated by one hour. The anterior descending arteries were ligated near their origins. The ectopic rhythms produced by coronary occlusion were present during the period from about 8 hours to 3 days following the operation. Lanatoside C in varied doses was given at intervals ranging from 10 hours to 13 days after occlusion. When given during the first 4 days, the ectopic threshold dose, either in the presence or absence of a preexisting ectopic rhythm, was found to be lowered to 0.1 mg/kg or slightly less, i.e., about 70 to 80% of the control threshold. After 4 days the ectopic threshold was not lower than the preoperative control except in four dogs which at the beginning of the test exhibited electrocardiographic patterns interpreted as aberrant conduction. Tests with 0.06 mg/kg produced no ectopic discharges at any time. Evidence from other sources indicates that this dose is more than sufficient to increase work output in a failing heart, therefore these findings may indicate that danger associated

with ventricular ectopic activity following coronary occlusion is not increased by conservative use of lanatoside C. The dose required to produce retching and vomiting was consistently lower than that which produced ectopic beats in unanesthetized dogs.

Late development of ectopic ventricular activity following coronary occlusion

A SIDNEY HARRIS and ROBERT H KOKERNOT (by invitation) *Dept of Physiology, Baylor Univ College of Medicine, Houston, Texas* The anterior descending arteries of the hearts of 25 dogs were ligated proximal to any large branch. The dogs were anesthetized with morphine and a minimal dose of barbitol sodium (180 mg/kg). Under such anesthesia the hearts are fully susceptible to the development of ventricular ectopic systoles. To prevent the occurrence of rapid ectopic discharges and death via ventricular fibrillation within the first 10 minutes following occlusion, the occlusion was made in 2 stages. Partial occlusion was followed 30 minutes later by total obstruction. No animals so operated were lost during the early period in which, following one-stage occlusion, the usual mortality is near 50%. Frequent electrocardiographic observations and records were made. Ventricular ectopic systoles began to appear in significant numbers after periods of 6 to 12 hours in the different experiments. Eight hours was the most common time for the beginning of the rise of ectopic activity beyond an occasional premature beat. At the end of 12 hours ectopic activity was prominent in every animal studied through the period except one that maintained a sinus rhythm. One animal had a moderate ectopic frequency from the time of occlusion. Typically, a maximal ventricular tachycardia was reached between 10 and 21 hours, and ectopic activity persisted from 2 to 4 days. Large highly necrotic gross infarcts were found in almost all hearts upon sacrifice (10 to 22 days).

The uptake of radiocalcium by the skeleton

HAROLD E HARRISON and HELEN C HARRISON (introduced by NATHAN W SHOCK) *Dept of Pediatrics, The Johns Hopkins Univ Medical School, and Pediatric Division, Baltimore City Hospitals, Baltimore, Md* The equilibrium between skeletal calcium and calcium of the body fluids was studied by determinations of the uptake of Ca^{45} by the bone of animals given $\text{Ca}^{45}\text{Cl}_2$ solution. Groups of rachitic rats, rachitic rats treated with vitamin D., and control rats were used. During the experimental period, some of the animals received a high calcium diet and others, a diet low in calcium. The animals were sacrificed at intervals from 2 hours to 2 weeks following administration of Ca^{45} . Measurements of the radioactivity of the calcium of blood serum and the skeleton were made, and the

ratio of Ca^{45} to Ca^{40} expressed in terms of counts per second per mgm calcium. Equilibrium between body fluid calcium and bone calcium occurs rapidly and in some instances is reached by 72 hours. Epiphyseal bone calcium attains equilibrium with serum calcium more rapidly than that of diaphyseal bone, and the rate of equilibrium is not related to the rate of bone salt deposition. The uptake of Ca^{45} by the skeleton is not a measure of new bone salt addition. Following introduction of Ca^{45} into the body fluids exchange of Ca^{40} of the skeleton for Ca^{45} of the body fluids occurs until the ratio of these isotopes is the same in both phases.

Effect of cinchophen on the secretory activity of Brunner's glands. K. HARTIALA (by invitation) and M. I. GROSSMAN, *Dept. of Clinical Science, Univ. of Illinois College of Medicine, Chicago, Ill.* Experiments were carried out to determine whether cinchophen when given in doses known to produce ulcers in the dogs has any effect on the Brunner's gland secretion. The juice was obtained either from pouches or everted flaps made from the first part of the duodenum. The original blood supply and nerve connections were maintained. 200 mg of cinchophen per kg of body weight was given orally daily for 4 days to 6 dogs. It was noted that the basal secretion was markedly affected after the cinchophen administration. The alterations took place usually after the second day and in some cases even in the first day after the ingestion of drug. The total output of juice diminished to less than a half of the volume of that of the controls. Both the alkali content and the pH were decreased although the great decrease in the total alkali output was mostly a result of the decreased amount of juice secreted. The mucous content was not analysed but in the cases most affected by cinchophen the juice became thinner and was waterish. There was also a decrease in the volume of juice secreted in response to a standard test meal (Pard, milk, white bread).

Inhibition of activity of visual receptors by illuminating nearby retinal areas in the *Limulus* eye. H. K. HARTLINE, *Dept. of Biophysics, Johns Hopkins Univ., Baltimore, Md.* and the *Johnson Research Foundation, Univ. of Pennsylvania, Philadelphia, Penna.* A discharge of impulses in a given single optic nerve fiber from the eye of *Limulus* can be elicited only by the illumination of some one particular facet of the eye, containing the receptor that gives rise to that nerve fiber. It has been found that illumination of neighboring areas of the eye, while unable to initiate activity in a given fiber, can nevertheless affect the responses to illumination of its receptor. A steady discharge of impulses was obtained by a small spot of light confined to the appropriate facet, illuminating nearby facets then caused a

slowing of the discharge. The frequency dropped markedly at first (after a latency of 2-4 sec.), then rose somewhat, on turning off the adjacent illumination, the frequency increased and within 4 sec. had recovered its original value. This inhibitory effect was greater the higher the intensity and the greater the area illuminated, it decreased with increasing distance between the particular facet and the neighboring area illuminated. The role of this effect in enhancing visual contrast is obvious: brightly illuminated areas inhibit the activity from dimly lighted regions more than the latter inhibit the activity from the former. In *Limulus*, axons of the receptor cells enter a non-ganglionic plexus before leaving the eye via the optic nerve, by recording from fibers between the receptors and the plexus, it could be shown that the inhibitory effect of adjacent illumination depended on the integrity of the nervous connection between the receptor and the plexus.

Effects of experimental anaemia on the circulation in dogs. J. D. HATCHER (by invitation), F. SUNAHARA (by invitation), J. C. VAN NOORDWIJK (by invitation) and O. G. EDHOLM, *Dept. of Physiology, Univ. of Western Ontario, London, Canada.* The cardiac output, peripheral blood flow, and blood volume have been measured before, during and after the development of anaemia by small daily haemorrhages. While the haemoglobin level is falling, there is a slight decrease in cardiac output and right auricular pressure. This is considered to correspond to the hypodynamic phase of Howarth and Sharpey-Schafer. When the haemoglobin level falls to 50% or less of the initial value, the cardiac output and the right auricular pressure increase abruptly. At this stage, the daily haemorrhages are stopped, the cardiac output rises to reach a peak value averaging 160% of the pre-haemorrhage outputs. The greatest cardiac output is obtained approximately 2-4 days after the cessation of haemorrhage, at a time when the haemoglobin value is still at its lowest level. The hyperdynamic phase persists for 2-5 days and then the cardiac output declines reaching a normal level at a time when the haemoglobin level has recovered to 75-500% of the pre-haemorrhage value. Oxygen consumption is increased significantly during the hyperdynamic phase. The saturation of the mixed venous blood diminishes during the hypodynamic phase and rises in the hyperdynamic phase. The total blood volume decreases approximately 25% during the period of haemorrhage, while the plasma volume remains relatively unchanged. The plasma volume and total blood volume rise during the hyperdynamic phase, but the overall changes are not marked.

Consciousness and reflex potentialities of dogs during immersion hypothermia. H. O. HARTNICK

and A H HEGNAUER *Dept of Physiology, Boston Univ School of Medicine, Boston, Mass* Random observations on CNS activity on more than 150 dogs during immersion hypothermia are worthy of record The choice of pre-cooling anesthetic is of paramount importance Light ether or cyclopropane, withdrawn periodically, reveals with considerable accuracy the rectal temperature (R T) at which consciousness is abolished by cold narcosis This varies from 22.5° to 26° R T (24.5° to 28° cerebral temperature) The 22.5° observation was made during rewarming, at which point the dog righted his head and attempted standing Failure to stand was due to intense shivering and limb spasticity In one experiment after withdrawal of cyclopropane the dog strained at his bonds at R T 20.5 and again at 15.8 (cerebral temperatures 23.5° and 20.5° resp) Spontaneous reflex activity was noted as follows shivering, which under pentothal-Na is rarely observed below 21°, may under light ether be evident at 16° or 17°, vocalization (whimpering, whining, moaning) to 17°, barking in one case at 20°, spontaneous jaw, head or limb movements to 17° (exceptional case 15.8°), spontaneous respiration in one preparation at 11.8° (2/min), in 2 preparations below 13.6°, and a total of 12 dogs breathed at R T 16° or lower (cerebral temperature 20° or less) After pentothal alone consciousness during rewarming is never observed at rectal temperatures below the thirties, although the last injection may have been made some 2 or 3 hours earlier Furthermore, the temperatures at which the above reflexes disappear are all higher than those recorded

Ascorbic acid metabolism in patients with certain gingival disturbances RAYMOND HAYES (by invitation), WALTER M BOOKER and MARIANNA B SEWELL (by invitation) *Dept of Oral Medicine, College of Dentistry, and Department of Pharmacology, College of Medicine, Howard Univ, Washington, D C* Fasting plasma ascorbic acid in patients suffering with various types of gingivitis was found to be significantly lower than in a control normal group of patients The cell ascorbic acid levels of the blood in the same patients was equal to or in some instances greater than that of the control groups By and large, only when there is deficiency in both plasma and cell ascorbic acid were clinical signs of gingivitis striking or even present When ascorbic acid is administered (orally or intravenously) to patients and to normal subjects, the plasma level rises faster than the cell level, suggesting something of a barrier between the plasma and the cells Many of the patients excrete ascorbic acid in the urine in greater quantity and at faster rate than the normal subjects Efforts are in progress to compare the rate of urinary excretion with the clinical state of the

patient regarding gingivitis There are presented some outstanding examples of extremely low kidney threshold regarding ascorbic acid excretion among some of the patients The low kidney threshold to ascorbic acid apparently bears no relationship to the general nutritional state of the patient in terms of plasma proteins and blood sugar Diminution of serum chlorides upon the intravenous or oral administration of 100 to 300 mg of ascorbic acid is seen in all patients and in normal subjects

Effect of pituitary adrenocorticotropin on the plasma hypertensinogen concentration of dogs F W HAYNES, P H FORSHAM (by invitation), G W THORN and L DEXTER (by invitation) *Dept of Medicine, Harvard Medical School, and the Medical Clinic, Peter Bent Brigham Hospital, Boston, Mass* The effect of purified hog anterior pituitary adrenocorticotropin (ACTH, Armour) on plasma hypertensinogen was studied in trained, unanesthetized dogs ACTH, without appreciable contamination with thyrotropic, gonadotropic and growth hormones, but containing posterior pituitary activity up to 0.08 units per mg, was used in daily doses equivalent to 20 to 80 mg of Armour standard (LA-1-A) Hypertensinogen was determined by incubation of plasma with an excess of hog renin and cat assay of the hypertensin formed Data are based on the mean of at least 4 satisfactory assays on each plasma sample In 5 experiments on normal dogs receiving ACTH, either intramuscularly in divided doses over a 3-day period or intravenously as an infusion over several hours, the hypertensinogen concentration increased for several days and then returned to its previous level The control hypertensinogen levels of these dogs (1.7-3.1 cat units per cc of plasma) were increased by 0.6 to 2.9 cat units after ACTH Adrenocortical activation was suggested by a significant fall in eosinophils during ACTH administration ACTH failed to influence the hypertensinogen concentration in an adrenalectomized dog Hypertensinogen and eosinophil levels failed to show a significant change in control experiments designed to test the effect of sampling and of posterior pituitary contamination in a normal dog

Corticosteroid release from the isolated adrenal gland OSCAR HECHTER *Worcester Foundation for Exptl Biology, Shrewsbury, Mass* Isolated beef and sheep adrenal glands were perfused with homologous citrated blood Following the addition of adrenocorticotrophic hormone (ACTH) it was consistently observed that the venous blood contains an increased amount of formaldehydegenic substances (F S) in the neutral chloroform fraction designed to concentrate adrenocortical steroids These F S may be obtained from perfusates by extraction of the acidified blood with chloroform or

chloroform-ethanol mixtures or by chloroform extraction of dialysates of blood. With both methods, it has been found that there is either slight or no release of F S from glands perfused in the absence of ACTH. In 5 experiments with beef glands, following the addition of ACTH (20 to 200 μg per cc) there is an average release of F S corresponding to 26 μg (Range 10–42) equivalents of 11-desoxycorticosterone per minute per gland (weights 15–20 gm). In some glands, increased F S output was maintained for as long as 4 hours. In 2 experiments with sheep glands the release of F S following ACTH was of the same order of magnitude per gm gland. Assay of fractions, from four different beef adrenal persates for glycolytic activity, using the method of Olson *et al* (*Endocrinology* 35: 430, 1944) revealed two to be active, 50 and 100 μg F S equivalent to 50 and 60 μg Compd E Kendall respectively. The other two extracts were inactive at a level of 100 and 400 μg F S. In 4 experiments, despite wide variations in dosage, the intrarterial injection of epinephrine consistently failed to release F S from perfused glands. The significance of these *in vitro* findings will be discussed.

Temperature gradients in dogs in immersion hypothermia. A. H. HEGNAUER, *Dept of Physiology, Boston Univ School of Medicine, Boston, Mass.* The procedure followed in this laboratory for producing rapid, drastic hypothermia in dogs (after preliminary anesthetization and required surgery—animals in supine position on dog board) is immersion to the neck in an iced bath at 2°–4° C. With the head end of the board a few inches higher than the foot the portion of the animal unimmersed includes the head, the ventral third of the thorax and all but the nape of the neck. The proportion of exposed to submerged body is approximately that obtaining when a man floats on water in a 'Mae West' life vest. Under these conditions there occur not only core to surface, but also cerebral (C T) to rectal temperature (R T) gradients. Cerebral, mediastinal (M T), right heart blood (B T) and rectal temperature as well as muscle and skin temperature (or some combination of these) is recorded continuously via Speedomax (Leeds & Northrup). Plotting R T linearly as abscissa and deviations therefrom as ordinate, curves are obtained from which the following conclusions may be drawn: 1) C T is higher than R T, and progressively so with decreasing R T. 2) M T, initially slightly below rectal, is equal to the latter at R T 36° and subsequently parallels the curve for C T, about 1° lower. 3) Right heart blood (B T) is initially $\frac{1}{2}$ ° less than R T, falls further on immersion and then crosses R T when latter reaches 28°, and thence parallels C T and M T. When R T reaches 12° the C T, M T, and B T are 18°, 17°, and 16° respectively. Skin temperature from submerged area rapidly approaches bath temperature. Muscle temperature (hind leg) cools more slowly than skin, but much more rapidly than R T.

Pulse rate and blood pressure of dogs in immersion hypothermia. A. H. HEGNAUER and H. O. HATERIUS, *Dept of Physiology, Boston Univ School of Medicine, Boston, Mass.* Average pulse rate (P R) and blood pressure of 18 lightly anesthetized dogs (sodium pentothal) obtained during cooling in an iced bath (2°–4° C) were plotted against the right heart blood temperature (B T). A thermocouple was placed in right heart with continuous recording on Speedomax in degrees centigrade. The pre-immersion P R was 155. Disregarding the initial abrupt increase and decrease in rate from moment of immersion to B T 36° the rate follows a smooth regression curve to B T 15° at which point the P R is 15. Between B T 36° and 26° the apparent $Q_{10} = 2.1$, and increases to 5.5 between 25° and 15°. Plotting $\log P R$ vs $1/T^\circ$ abs revealed no sharp breaks. Tentatively as a working hypothesis a regression curve ($Q_{10} = 2.5$) was constructed, passing through the origin of the experimental curve (at P R 155). The computed curve again coincides with the P R curve at B T 19°, when the two follow a similar course. Between B T 39° and 19° the P R curves lies well above the computed curve, and it is suggested the elevation is a measure of sympathetic activity at these temperatures.

Action of heparin on protoplasmic gelation. L. V. HELLBRUNN, *Dept of Zoology, Univ of Pennsylvania, Philadelphia, Penna.* Earlier studies from this laboratory have indicated that the gelation of protoplasm is similar to the clotting of blood. Before a cell divides, its protoplasm gels and the appearance of the mitotic spindle is preceded by the so-called mitotic gelation. In the egg of the worm *Chaetopterus*, this mitotic gelation is prevented by immersion of the eggs in dilute solutions of heparin. Suppression of mitotic gelation results in an inhibition of cleavage. Similar results were obtained with frog eggs. The initiation of mitosis in these eggs tends to be prevented by the presence of heparin. There is an indication, therefore, that in living cells the colloidal behavior of the protoplasm is to some extent at least determined by the equilibrium between thrombin-like substances and heparin or heparin-like substances. Actually, in the *Chaetopterus* egg there is direct evidence for the presence of either heparin or some substance which stains like it.

The role of the Sertoli cell in the testis-pituitary axis in men. CARL G. HELLER, WILLIAM O. MADDOCK (by invitation), EDWIN C. JUNGCE (by invitation), and WARREN O. NELSON, *Depts of Medicine and Physiology, Univ of Oregon Med*

School, Portland, Oregon, and Dept of Anatomy, Univ of Iowa Med School, Iowa City, Ia The supporting cell of Sertoli is claimed to elaborate a non-androgenic hormone whose role is to inhibit the secretion of pituitary gonadotrophin. If this is correct, no alterations in gonadotrophic output should occur in instances in which Sertoli cells remain intact and germinal cells disappear. Testicular biopsies in men with azoospermia or oligospermia have revealed 34 cases in which at least some of the seminiferous tubules were devoid of all germinal elements except the Sertoli cell. Such tubules constituted 10% to 100% of the total seminiferous tubules and were associated with either hyalinization of the basement membrane or with tubules having germinal cells present, or both. Despite the intact Sertoli cells, elevation above normal in the gonadotrophin titers was regularly encountered in cases having less than 70% of active tubules. A roughly direct proportionality exists between the height of the titers and the degree of spermatogenic failure. This suggests that the Sertoli cell does not enter into testis-pituitary regulation, but suggests that during active spermatogenesis, gonadotrophins are inactivated in the presence of incomplete or failing spermatogenesis, a smaller amount of gonadotrophin is utilized, allowing for a rise in titer.

Adrenal cortical function and the effect of adrenocorticotropin in myasthenia gravis LEON HELLMAN (introduced by R. E. WESTON) *Medical Division, Montefiore Hospital, New York City* Hypertrophy of the lymphoid tissues and the thymus occurs in many patients with myasthenia gravis and in patients and animals with adrenal cortical hypofunction. Atrophy of the thymus can be induced in animals by the administration of adrenocorticotropin (ACTH). Since surgical removal of the usually enlarged thymus appears to benefit patients with myasthenia gravis, ACTH was administered to patients with myasthenia gravis in an attempt to 'hormonally' remove their thymuses. Several adrenal cortical functions were studied in these patients. The subjects were 5 patients with classical myasthenia gravis, responsive to prostigmine, none of whom had demonstrable thymic tumors. Injection of 35 mg ACTH (Armour) produced the responses characteristic of normal adrenal function. Circulating eosinophils fell over 60%, circulating lymphocytes fell over 40%, and uric acid-creatinine ratio increased over 70%. Sodium restriction to 100 mg daily for 10 days did not produce adverse effects or a tendency to lose sodium. 17-ketosteroids were normal in 3 of the patients tested. 0.2 mg epinephrine produced a 60% fall in circulating eosinophils. Administration of 125 mg ACTH daily for 4 days to 3 patients produced the changes associated with adrenal

cortical hyperfunction. If anything, the patients' clinical courses were adversely affected. This may be related to the potassium diuresis or the altered intracellular-extracellular Na-K ratio produced by ACTH. Administration of 500 mg synthetic Compound A (supplied by Merck and Company) to 2 patients produced a temporary dramatic restoration of muscular function.

Effect of adrenocorticotropin in human chronic lymphatic leukemia LEON HELLMAN (introduced by R. E. WESTON) *Medical Division, Montefiore Hospital, New York City* The administration of adrenocorticotropin (ACTH) produced a decrease in circulating lymphocytes and eosinophils in the human and adrenal cortical extracts are said to produce a lymphopenia and regression of lymphoid tissue in mice with spontaneous lymphatic leukemia. Mice with marrow aspiration were injected with 25-125 mg ACTH (Armour). The initial peripheral white count ranged from 3000-400,000 WBC, the majority being in the upper range, and the lymphocytes were usually over 90% of the total WBC. After ACTH, no leukemic patient showed a significant decrease in circulating lymphocytes, but all except 2 showed a fall in circulating eosinophils of over 60%. Initial eosinophil counts tended to be low. Total WBC remained unchanged while the uric acid-creatinine ratio was usually increased over 60%. No changes were observed in lymph nodes removed from two patients before and after the ACTH. In contrast, 25 normal controls given simultaneous injections of equal amounts of the same ACTH, showed a fall of over 40% in circulating lymphocytes, a decrease of over 60% in circulating eosinophils, an increase in total WBC of 50-120%, and an absolute polymorphonuclear leukocytosis with a shift to the left. 25 cc lipo-adrenal cortex extract (supplied by the Upjohn Company) produced changes in normals and leukemics similar to ACTH. The effect of ACTH on the peripheral blood may be useful as a biologic test for lymphoid leukemia and has been used successfully in two patients with aplastic anemia. It is suggested that mouse lymphoid leukemia differs significantly from the human variety.

The concurrent feeding of amino acids RICHARD HENDERSON (by invitation) and ROBERT S. HARRIS *Nutritional Biochemistry Labs, Massachusetts Inst of Technology, Cambridge, Mass* Groups of weanling rats were fed a basal diet containing casein (30), corn starch (55.4), hydrogenated fat (10), tryptophan (0.17), histidine (0.13), salt mixture (4) and vitamin mixtures (0.36). Control groups received the basal diet + 1% lysine. Test groups received the basal diet and the basal diet + 2% lysine at alternate feedings. The lysine replaced equal weights of corn starch in the diet. Groups were fed (1) one hour and fasted 7

hours, (2) one hour and fasted 5 hours and (3) one hour and fasted 3 hours throughout successive experiments lasting 27 days. A time-interval feeder was devised for the automatic opening and closing of the feeding jars. Significant differences were noted in nitrogen retention and in bodyweight gain, weight gain per gram of diet eaten, weight gain per gram of lysine eaten. These differences were greater as the feeding intervals lengthened. Thus a delay of three hours or longer, in the feeding of lysine as a supplement to a lysine-low diet interfered with metabolism. Lysine must be fed concurrently with other amino acids in the diet for most efficient utilization by the rat.

Factors determining cerebral oxygen supply during positive acceleration J. P. HENRY, O. GAUER (by invitation), E. E. MARTIN (by invitation), S. S. KETTY (by invitation) and K. KRAMER (by invitation). *Aero Medical Lab., Air Materiel Command, Wright-Patterson Air Force Base, Dayton, Ohio*. Extraordinarily low mean cephalic arterial pressures of less than 20-30 mm Hg (blackout) can be endured during positive accelerations lasting as long as 3 minutes without loss of consciousness. When compared with the effects of a comparable drop in pressure during hemorrhagic shock, there is an unexpected retention of mental performance and orientation. In order more clearly to define the mechanisms involved, radial arterial and cerebral venous pressures, and arterial and cerebral venous oxygen saturations were measured in man during acceleration. These parameters were measured two at a time using electrically operated gauges for the pressures and a Kramer glass cuvette oximeter for the oxygen saturations. The fall in arterial pressure at head level induced by the acceleration was closely followed by a drop in jugular venous pressure. In spite of black-out (4.5 g) one subject still had 60 mm Hg mean pressure differential across the brain. The venous pressure became less negative as arterial pressure rose during the cardiovascular response to the sharp fall in arterial pressure induced in the carotid sinus by the acceleration. Arterial oxygen saturation also started to fall approximately 7 seconds after acceleration commenced and by the end of the 15 second run at 4.5 g it had attained approximately 90%. Further, after a 5-7 second delay the venous oxygen saturation fell and showed fluctuations paralleling the arterial and venous pressure changes. Typical changes in venous oxygen content were from 10.5 vols % resting to 7.5 vols % at blackout. Thus arterial as well as venous oxygen content should be known to determine the oxygen supply of the brain during prolonged acceleration. The extent of the fall in cerebral venous oxygen content at blackout points to an inadequacy of cerebral oxygen supply.

Some responses of man to internal thermal stimulation AUSTIN HENSCHEL, HENRY LONG-STREET TAYLOR and ANCEL KEYS. *Laby of Physiological Hygiene, Univ. of Minnesota, Minneapolis, Minn.* The gastric motility, blood sugar concentration, blood pressure, pulse rate and finger skin temperature responses to internal thermal stimulation were measured on a total of 16 young men who were free from signs of gastrointestinal and cardiovascular abnormalities. The thermal stimulus was a standard ice cream mixture to which 15% barium sulphate was added. Either 400 or 100 gm portions of the test meal was eaten in exactly 5 minutes, the test meal temperature was -8°C , 26°C or 65°C . Gastric motility as measured by gastric emptying time was not altered by the temperature of the test meal. The blood sugar concentration increased a maximum of 22 mg % 30 minutes after the -80°C test meal, the maximum after the 65°C test meal was 12 mg %. Finger skin temperature decreased an average of 3.25°C at 10 minutes after the -8°C test meal and was not back to normal at 50 minutes, the 26°C and 65°C test meals had no effect. An increase of 14.8 mm Hg systolic and 17.6 mm Hg diastolic blood pressure and 20.2 beats per minute pulse rate occurred during ingestion of the 400 gram test meal at -8°C . The values were normal within 2 minutes after completion of the meal. There was no blood pressure, pulse rate or skin temperature response to the 100 gram test meal served at -8°C .

Thermistors as applied to temperature measurements in animals J. F. HERRICK and E. GLARBORG. *The Mayo Foundation, Rochester, Minn.* The thermistor (thermally sensitive resistor) has proven a convenient, simple, rugged and accurate method for measuring the temperature of various animal tissues in our laboratory. This type of thermometer introduces a new order of sensitivity so far as resistance thermometers are concerned. We are using thermistors for measuring temperatures as low as -40°C in certain investigations on frost-bite and also temperatures as high as animal tissues can be heated without irreversible changes being produced. The thermistor is particularly suitable for measuring temperature changes in bone and bone marrow. Rectal temperatures of small animals can be recorded continuously, quite conveniently. The thermistor can be introduced easily into arteries, veins, muscle and subcutaneous tissue and left in place throughout the day when studying changes in temperature caused by various methods of heating or cooling. We have been using the thermistor for measuring changes in skin temperatures of the dog for almost two years and find it a very convenient method. All temperatures may be recorded on moving photographic film or by

direct observation Temperatures may also be observed at a considerable distance from the site of measurement The various types of thermistors, the necessary equipment for measuring temperatures and the method of calibration will be described, and representative data discussed

Mechanism and management of edema GEORGE R. HERRMANN, JOHN W. CHRISS, E. H. SCHWAB and PAUL M. SIMS *Univ of Texas Medical School, Galveston, Texas* The newer conceptions of cardiac output and renal blood flow in the genesis of sodium retention and edema formation are discussed The influence of mercurials on sodium output is stressed Thiomerin—an organic mercurial with a sulfhydryl radical and a new diuretic with low toxicity—is discussed Satisfactory diuresis has been obtained following both subcutaneous and intravenous injections Thiomerin given intravenously has also been studied for any significant electrocardiographic changes

Myocardial insufficiency and its management with especial reference to a new and safe mercurial diuretic GEORGE R. HERRMANN, JOHN W. CHRISS, E. H. SCHWAB, MILTON R. HEJTMANCIK and PAUL M. SIMS *Univ of Texas Medical School, Galveston, Texas* Sodium retention is the most important factor in edema formation in congestive heart failure Decreased cardiac output results in diminished renal circulation, with 90-fold sodium reabsorption Sodium, with its retained water added to the extracellular fluids, produces edema Organic mercurial decrease tubular reabsorption of electrolytes and water, producing diuresis A 70-fold sodium excretion accompanies mercurial diuresis Intravenous mercurial diuretics have resulted in sudden death, with ventricular fibrillation demonstrated in 2 cases, and 20% of patients show cardiac mechanism disorders In attempting to counteract this myocardial toxicity, a sulfhydryl group was substituted for theophylline This mercapto, thiomerin, is less toxic than any other mercurial diuretic Thiomerin is well tolerated subcutaneously, and produces satisfactory diuresis Intravenous use to compare its effects on the heart with that of other mercurials has resulted in a minimum of even slight reactions This drug is potent, less irritating, and practical to use

An estimation of the regional distribution of the cutaneous heat losses ALRICK B. HERTZMAN and WALTER C. RANDALL *Dept of Physiology, St Louis Univ School of Medicine, St Louis, Mo*

We have explored the possibility of calculating the total heat losses from the surface of the body and their regional distribution from the estimations of cutaneous blood flows (photoelectrically recorded skin pulses) and the A-V temperature differences (oral temperature minus skin temperature) in the various skin regions Total heat losses

thus estimated approximate those which are calculated from O_2 consumptions and changes in average body temperature The corresponding fractions of the total heat losses as contributed by the various skin regions of the resting nude subject are approximately trunk 25, leg 19.5, arm 14.2, face 15.5, hand 15.2, foot 10.7% These fractions vary from subject to subject, with the metabolic rate and environmental conditions The various skin regions may be grouped (in resting nude subjects) into two divisions one group (face, palm, plantar surface and digit pads) characterized by high rates of blood flow (above $0.06 \text{ cc/cm}^2/\text{min}$) and high rates of heat loss (above $0.2 \text{ calories/cm}^2/\text{min}$), the other group (trunk, leg, arm and dorsal surfaces of hand and foot) characterized by low rates of blood flow (below $0.03 \text{ cc/cm}^2/\text{min}$) and low rates of heat loss (below $0.08 \text{ calories/cm}^2/\text{min}$) The value of the fraction, blood flow divided by the difference in temperatures of skin and air, shows a similar regional distribution, suggesting that differences in evaporative rates may set flow levels in the corresponding skin regions

Determination of acetylcholine in cell-free enzyme systems by a colorimetric method SLOMO HESTRIN and EMILY F. HEDAL (introduced by DAVID NACHMANSOHN) *Dept of Neurology, College of Physicians & Surgeons, Columbia Univ, New York City* The development of a chemical micro-method for acetylcholine has permitted assay of this ester in the presence of choline and acetate in large excess The method utilizes the fact that esters are rapidly converted at alkaline pH by hydroxylamine into corresponding hydroxamic acids The latter may be determined colorimetrically as in the procedure for acyl assay which has been described by Lipmann and Tuttle

Results obtained with the use of this method in experiments on synthesis of acetylcholine by acetylcholine-esterase and choline acetylase will be discussed

The antagonism of cinchona alkaloids to the circulatory effects of intravenous epinephrin EDWIN P. HIATT *Dept of Physiology, Univ of North Carolina, Chapel Hill, N. C.* The effect of standard intravenous doses of epinephrin (0.5 cc of $1:10,000$) on arterial blood pressures of unanesthetized dogs was recorded photographically using a membrane manometer The dogs were then given several oral doses of quinine or quinidine sulfate (15 mg/kg at intervals of several hrs) attaining a sustained plasma concentration of 5 to 10 mg/l These drugs abolished both the pressor effect and the changes in rate which usually follow epinephrin injection Lower concentrations of the alkaloids had less effect and larger doses of epinephrin overcame the inhibitory effect of the alkaloids These results confirm the effects reported

repeatedly since 1919 by investigators using intravenous injections of the cinchona alkaloids without measurement of plasma alkaloid concentrations. The reciprocal effect was shown by Dreisback and Hanzlik (*Jour Pharm & Exp Therap* 83 167, 1945) and others, using epinephrin to counteract the depressor effect of intravenously injected cinchona alkaloids. We have previously demonstrated that these drugs cause renal vasodilatation and decrease the blood pressure of dogs with experimental neurogenic hypertension. Perhaps these effects are due to an inhibitory effect on adrenergic sympathetic endings. Since it has been demonstrated that these alkaloids can inhibit certain parasympathetic endings as well as motor fibers to skeletal muscles (*Jour Pharm & Exp Therap* 85 55, 1945), it may be these agents can inhibit all motor nerve endings.

Effect of prostigmine and urecholine on human gastric motility N C HIGHTOWER, JR (by invitation), C F CODE, F T MAHER (by invitation) and C G MORLOCK (by invitation) *Section on Physiology, Mayo Foundation and Division of Medicine, Mayo Clinic, Rochester, Minn*. Gastric motility was recorded by means of a system consisting of an undistended balloon containing approximately 28 cc of water and an air cushion of 122 cc between the water-filled balloon and a glass-spoon pressure recorder. The volume pressure coefficient of the system was 0.13. The pressures developed in the balloon were recorded photographically, 1 cm of H₂O pressure producing 1 mm of deflection in the record. Studies were made in normal human beings during fasting, and after the intramuscular injection of 0.5 mg of prostigmine and after the oral administration of 5 mg of urecholine. A quantitative analysis of the photographic records has been attempted, and the results of this analysis have been summarized statistically. The data show that the rate of type II contractions (propulsive type) never exceeded the rate of the smaller type I contractions ('20 second rhythm' of Carlson), and that the administration of the drugs in question did not alter this relationship. Neither drug changed significantly the total amount of motility activity in the stomach, nor did they affect the incidence of the various types of motility. The drugs produced a slight increase in the mean height of the type II contractions, but the significance of this change is questioned. The study supports the hypothesis that the small type I contractions represent a basic fundamental rhythmic sequence of motility activity in the stomach.

Effect of tridione on convulsions caused by diisopropyl fluorophosphate (DFP) H E HIMWICH, C F ESSIG (by invitation), and J L HAMPSON (by invitation) *Army Chemical Center, Medical Division, Edgewood, Md*. In a series of more than

100 experiments diisopropyl fluorophosphate (DFP) was injected into one common carotid artery of curarized rabbits under artificial respiration. With the small amounts of atropine required to protect the heart from succumbing to excessive acetylcholine, it was possible to give DFP in dosage large enough to produce convulsions and still maintain life. Changes were noted in the electroencephalogram which in their most severe form resembled the condition of status epilepticus. Since the subsequent analysis of the brain tissues disclosed a great fall in the action of cholinesterase, the enzyme which hydrolyzes acetylcholine, the changes in the brain waves were presumably produced by excessive acetylcholine. In 10 experiments the intravenous administration of tridione corrected the grand mal type of electroencephalogram in doses of 0.1 to 0.3 gm/kg and restored the electroencephalogram to normal with doses of 0.2 to 0.4 gm/kg. In other experiments, in which tridione was injected before DFP, tridione exhibited a preventive action for approximately 4 hours. Though the grand mal electrical pattern was prevented the normal electroencephalogram was not maintained and increased activity was observed. The administration of tridione in no way influenced the profound fall in cholinesterase activity. It would seem therefore that tridione counteracts the effects of excessive concentrations of acetylcholine in the brain.

Cholinergic nature of the vestibular receptor mechanism, forced circling movements (motion picture). H E HIMWICH, C F ESSIG (by invitation), J L HAMPSON (by invitation), P D BALES (by invitation) and A M FREEDMAN (by invitation) *Medical Division, Army Chemical Center, Md*. Diisopropyl fluorophosphate (DFP) was injected into the common carotid artery of animals belonging to four species: Rabbits, cats, dogs and monkeys. Though the dosage required varied with the species, the results were similar. The head turned to the side opposite to that of injection and compulsive circling movements were made to the side opposite, hence the name adverse syndrome. Labyrinthectomy or section of the eighth nerve prevented the development of the syndrome when the injection was made on the operated side but not when the DFP was introduced into the other common carotid artery. Either atropine or scopolamine cured the syndrome.

Ketosis in diabetic humans in response to the stress of interpersonal adjustment. LAWRENCE E HINKLE, JR and GEORGE T CONGER (introduced by STEWART WOLF) *Dept. of Medicine and Psychiatry of the New York Hospital and Cornell Univ. Medical College, New York City*. Eleven diabetic individuals were subjected to experimental study. Increased glycosuria and ketosis

were observed repeatedly during conflicts associated with fear, depression, frustrated anger and, as far as could be ascertained in the absence of significant changes in diet, insulin or activity. Accordingly, 2 of these subjects were studied in the hospital where diet, insulin and activity were carefully controlled. A marked increase in glycosuria in one, and clinically typical keto-acidosis in the other, were induced when the individuals were subjected to significant threats to their emotional security. Three of the subjects were studied in short-term experiments under sodium amytal narcosis. In all a significant rise in the concentration of ketone bodies in the peripheral blood occurred during a discussion of their personal conflicts. Following reassurance, in each case the ketones fell to lower levels. Ketone measurements were made by the micro-method of Greenberg and Lester. Blood samples were also obtained from a catheter introduced directly into the hepatic vein. Significant elevations of ketone content during tension and conflict with return to control levels during reassurance were demonstrated.

Acute renal cortical ischemia produced by stimulation of the pressor area of the cerebral cortex. E. C. HOFF, J. F. KELL, JR. (by invitation), NELSON HASTINGS (by invitation), E. H. GRAY (by invitation) and D. M. SHOLES (by invitation). *Neurological Science Laby of the Medical College of Virginia, Richmond, Va.* Green and Hoff (*Am J Physiol* 118: 641, 1937) reported in cats and monkeys that limb volume usually increased while kidney volume diminished during pressor responses evoked by electrical stimulation of the cerebral cortex. Denervation of the kidney abolished this renal vasoconstriction so that the kidney passively dilated during the mean blood pressure rise. In the present experiments, acute blood pressure rises, lasting 15 to 90 seconds, were evoked by stimulation, unilaterally, of foci on gyrus preceus, gyrus sigmoideus, and orbital and mesial surfaces of the cat's cerebral cortex. In each experiment, one side only of the cerebral cortex was stimulated repeatedly for 1 to 2 hours using an inductorium or square-wave generator. Finally, during the height of a maintained pressor response, 30 to 50 cc of India Ink solution were injected into the right common carotid artery towards the aorta. There was pronounced vasoconstriction in the cortex of both kidneys as evidenced by virtual exclusion of the ink from the renal cortical vascular bed. This was in sharp contrast to findings in unstimulated control animals, in which both kidneys were deeply injected throughout. It is concluded that bilateral renal cortical ischemia results from excitation of the pressor area of the cerebral cortex, and that this vasoconstriction is part of the generalized vaso-motor response underlying the acute experimental

blood pressure rise. Possibly certain abnormal cerebral activity in man may result in persistent or recurrent renal cortical ischemia, and this mechanism may lie at the basis of essential hypertension.

Nature of apneusis and the pontine influence on respiration. HEBBEL E. HOFF and C. G. BRECKENRIDGE (by invitation). *Dept of Physiology, Baylor Univ. College of Medicine, Houston, Texas.* Dogs decerebrated by transection after occlusion of the carotids and the basilar artery at the lower border of the pons universally exhibit apneustic breathing, after transection encroaching on the pons and vagotomy. Apneustic breathing, consisting of alternate periods of inspiratory spasm and expiration at slow rates (1 or 2/min or less), is in the dog capable of maintaining life for several hours. When the carotids are occluded only during transection, pontine section and vagotomy produce apneusis in the majority of experiments, but certain animals show 'normal' respiration. Animals showing apneustic breathing resume 'normal' breathing terminally as the preparation deteriorates. When a further section encroaching on the medulla is made in 'apneustic' animals, the phases of inspiratory spasm are converted into periods of phasic 'normal' inspiration and expiration akin to Biot's breathing, often reverting to 'normal,' or 'normal' breathing appears immediately. Intravenous injection of cyanide produces apneusis or prolongs and intensifies it. When the carotid bodies and sinuses are denervated, apneusis does not appear after pontine decerebration and vagotomy, 'normal' or Biot's breathing alone occurs.

It is concluded that a) the medullary respiratory center can maintain periodic respiration in the absence of the pons and the vagi, b) apneusis represents an exaggerated inspiratory response to anoxemic stimulation via the carotid bodies 'occluding' the normal respiratory action of the medullary center, and c) such enhancement probably represents unchecked activity of the pontine portion of the midbrain facilitatory center.

Failure of topical calcium and magnesium to prevent eugenol-induced desquamation of gastric mucous epithelium. FRANKLIN HOLLANDER and SHIRLEY D. KRAUS (by invitation). *Gastroenterology Research Laby, Mount Sinai Hospital, New York City.* Previous studies have demonstrated that the mucigogue action of topical stimuli on the gastric mucosa of Heidenhain pouch dogs is usually accompanied by extensive desquamation of the surface epithelium, probably because of a loosening of the cement substance. A similar, though less marked, decrease in cellular cohesion may also underlie the invasive character of cancerous tissue, and evidence is accumulating in the literature that Ca- and Mg-ions are of considerable importance for maintaining the integrity of the cell-

binding mechanism in such tissue—as well as in several varieties of normal tissue from lower forms of life. Therefore, the present study was designed to determine whether the shedding of gastric mucous epithelium, induced by 1% aqueous eugenol alone, can be influenced markedly by the addition to this mucicogue-desquamating agent of CaCl_2 (0.02, 0.04, and 0.06%), alone or with MgCl_2 (0.01 and 0.03%). NaHCO_3 was added to adjust the pH to about 7. Mucus specimens, collected in 4 half-hour intervals following stimulation, were examined for viscosity, opacity, and the presence of cells (microscopically). No essential difference in these characteristics was observed between these experiments and controls without inorganic salts. Further experimentation is required to show whether the desquamating effect of eugenol emulsion is entirely independent of Ca- and Mg-ions, even though these may be part of the cement substance, or whether this effect is so powerful, even with 1% concentration, that it completely overcomes the influence of those ions under the conditions of these experiments.

Effect of sympathetic blocking procedures and of sympathectomy on peripheral blood flow. S. W. HOOBLER, J. W. AVERA, W. J. LITTLE, M. M. PEET and R. C. BASSETT (introduced by A. H. SMITH). *Depts. of Medicine and Surgery, Univ. of Michigan Hospital, Ann Arbor, Mich.* Certain sympathetic blocking techniques all of which abolished toe-thigh temperature gradients were studied by means of the venous occlusion plethysmograph. Resting blood flow in the foot averaged 0.7 cc/100 cc limb volume/minute (range 0.5–1.0). Average maximum flow after reflex body heating was 4.5 cc (range 2–7), after 500 mg tetraethylammonium chloride intravenously. 7.6 cc (2.8–10.3), after unilateral paravertebral block (L1–L3). 18 cc (11–26), after caudal anesthesia (1.5% metycaine to D3) or spinal anesthesia. 34 cc (16–60), within 12 hours after lumbar sympathectomy in 3 cases. 30.1 cc (12–36). In the latter instances the early post-operative result corresponded well with pre-operative paravertebral block of spinal anesthesia. The disparity between increase in digital temperature and increase in blood flow as determined in the plethysmograph was emphasized by an observation under caudal anesthesia utilizing 0.75% metycaine. In this hypertensive patient skin temperature gradient was abolished and anesthesia to pin prick as well as anhydrosis occurred to a level of D2. The blood pressure did not fall nor was there a measurable increase in blood flow in the foot. It may be concluded that complete block of the appropriate sympathetic ganglia or spinal vasomotor outflow can produce very great increases in foot blood flow, but that total block can not be assumed from

abolition of skin temperature gradient or of sudomotor activity alone.

After 3 out of 4 sympathectomies, plethysmographic measurements showed a reduction to pre-operative levels in 3 to 7 days. This was maintained thereafter for periods up to 15 months despite continued elevation of the digital temperature and anhydrosis.

Blood temperature in the heart and blood vessels of the dog. STEVEN M. HORVATH, E. L. FOLTZ (by invitation), A. RUBIN (by invitation) and B. K. HURT (by invitation). *Dept. of Physical Medicine, Graduate School of Medicine and the Dept. of Pharmacology, School of Medicine, Univ. of Pennsylvania, Philadelphia, Penna.* Temperatures of the blood, tissues, skin and rectum in anesthetized dogs were determined. Courmand type catheters with thermocouples at the tip were placed roentgenoscopically in the coronary sinus and the right ventricle or pulmonary artery. Smaller catheters were similarly inserted into the femoral artery and vein. The emf developed by the thermocouple was measured with a type K-2 Leeds and Northrup potentiometer. Since morphine-nembutal anesthesia has a tendency to lower body temperature, it was possible to study the temperature gradients at different rectal temperatures. The table below presents the mean temperatures and gradients obtained in 19 experiments on 11 animals. The rectal temperature was used as the point of reference in determining the gradients.

LOCATION OF CATHETER	$^{\circ}\text{F}$	$A(T - R)$
Rectum	99.1	
Rt. ventricle	98.7	-0.44
Pulmonary artery	98.7	-0.40
Coronary sinus	98.9	-0.20
Femoral artery	98.3	-0.84
Femoral vein	96.6	-2.51
Thigh muscle	97.6	-1.47
Thigh, subcutaneous	96.5	-2.64
Thigh, skin	92.1	-7.04

The work of the heart was altered variously with intravenous injections of epinephrine, aminophylline and methedrine and with inhalations of amyl nitrite. The temperature of the blood in the right heart during the action of these drugs was determined and the data will be discussed.

Determination of filtration rate and renal plasma flow in dogs without analysis of urine. C. RILEY HOUCK. *Division of Physiology, Univ. of Tennessee, Memphis, Tenn.* The renal plasma clearances of sodium p-aminohippurate (PAH) and mannitol were determined simultaneously by 1) the plasma slope method without urine analysis, and 2) the conventional urine collection method, and the values compared. According to Newman,

Bordley, and Winternitz (*Bull Johns Hopkins Hosp* 75 253, 1944), the renal clearance (C) of a substance is the product of its volume of distribution in the body (Vc) and the rate of disappearance from plasma (S). Under nembutal anesthesia, 4 dogs were injected intravenously with 5 gm of mannitol and 750 mg of PAH through a calibrated syringe. After 40 minutes, 5 10-minute blood samples were drawn, during which time urine was collected through an indwelling bladder catheter. In order to test for extra-renal loss of these substances, the dogs were subsequently bilaterally nephrectomized and 5 more 10-minute blood samples drawn. The urine clearance/slope clearance ratios for the 4 dogs were for mannitol 0.940, 0.923, 0.956, and 0.781 (av 0.90), and for PAH, (no determination on first dog), 1.052, 0.956, and 0.872 (av 0.96), respectively. In every case, extra-renal disappearance of PAH and mannitol was zero. Except for one dog, it is apparent that the slope clearance of either PAH or mannitol can be substituted for the respective urine clearance. Consequently, it may be concluded tentatively that glomerular filtration rate and renal plasma flow can be determined in dogs by the analysis of plasma alone without the collection and analysis of urine.

Disappearance of mannitol and PAH from plasma of bilaterally nephrectomized dogs
C RILEY HOUCK *Division of Physiology, Univ of Tennessee, Memphis, Tenn*. For mannitol and sodium p-aminohippurate (PAH), the volume of distribution (Vc), the rate of disappearances from plasma (slope or proportion of Vc cleared of each substance per minute), and the clearance (extra-renal) (C) were determined in 16 bilaterally nephrectomized dogs under nembutal anesthesia according to the procedure of Newman, Bordley, and Winternitz (*Bull Johns Hopkins Hosp* 75 253, 1944). Immediately after nephrectomy, 65 mg of PAH (16 dogs) and/or 1700 mg of mannitol (8 dogs) were injected rapidly intravenously from a calibrated syringe. After 40 minutes, from 5 to 8 venous blood samples were drawn at 10-minute intervals and analyzed. For mannitol, $V_c = 246$ cc/kg, $S = 0.0785\%/min$, $C (= V_c S) = 0.168$ cc/min/kg. For PAH, $V_c = 280$ cc/kg, $S = 0.239\%/min$, $C = 0.796$ cc/min/kg. It is apparent that the volumes of distribution of PAH and mannitol are very similar. Furthermore, the extra-renal loss of PAH from plasma is greater than the loss of mannitol. When compared to the total urine (renal + extra-renal) clearances in normal dogs (Houck, *Federation Proc* 7 339, 1948), the mannitol clearance in these nephrectomized dogs (extra-renal clearance) is only 4%, and the PAH extra-renal clearance only 6% of the respective total urine clearance. Consequently, in calculating the clearance of PAH and mannitol in intact normal

animals, by use of the slope method, the extra-renal clearances can be ignored because the extra-renal loss is negligible.

Vascular perfusion of the prostate gland of the dog
PERRY B HUDSON (by invitation), W W S BUTLER III (by invitation), HERBERT BRENDLER (by invitation) and W W SCOTT *James Buchanan Brady Urological Inst, Johns Hopkins Hospital, Baltimore, Md*. For the first time a reliable surgical technique has been devised which allows perfusion of the prostate gland through its normal arterial and venous channels. This preparation is accomplished by ligation of all branches of the abdominal aorta and inferior vena cava except for the arteries and veins on each side which constitute the vascular supply to the prostate gland. The autonomic nerve supply may be preserved. The urethra is preserved permitting cannulation for collection of prostatic fluid during perfusion of the gland. This preparation is proving useful in the study of the metabolism of the dog prostate gland, offering certain advantages over purely *in vitro* techniques.

Active salt transport and its regulation in the isolated frog skin
ERNST G HUF (introduced by ERNST FISCHER) *Baruch Center of Physical Medicine and Dept of Physiology, Medical College of Virginia, Richmond, Va*. Freshly isolated frog skin actively transports salt from its natural outside to its natural inside (accumulation effect). Experiments have been carried out using 'inside out' skin bags, formed of the skin of the hind limbs. The bags were filled with 5 ml of Ringer solution and immersed in 2.5 l of Ringer solution of the same concentration, this was varied in different experiments from 4 times up to 20 times its normal concentration. After 12 hours, less fluid of a lowered salt concentration was left in the bag. The weight of the filled bag at the end of the experiment was always lower than the weight at the beginning, indicating a transport of fluid through the skin. An increase in weight of the bag was observed in experiments where the Ringer solution was poisoned with NaCN (0.01 M). In this case the amount and the concentration of the Ringer solution placed in the bag was not diminished appreciably at the end of the 12-hour period. The accumulation effect is greatest when the skin is exposed to diluted Ringer solution and decreases with increasing concentration of the Ringer solution. Apparently the concentration of the salt solution regulates the mechanism of accumulation of salt. The endocrine and the nervous system seem to have little regulatory influence.

Toxins of *Streptococcus pyogenes* and cell respiration
F R HUNTER (introduced by A K PARPART) *Dept of Zoological Sciences, Univ of Oklahoma, Norman, Okla*. The effect of toxins of *Streptococcus pyogenes scarlatinae* on the rate of

O₂ consumption of several types of cells was studied. Almost complete inhibition was found using chicken erythrocytes, dogfish (*Mustelus canis*) erythrocytes, *Asterias* eggs and fertilized *Arbacia* eggs, the rate of respiration in the last instance being essentially the same as that of unfertilized eggs. Since it has previously been suggested that unfertilized *Arbacia* eggs respire through a non-ferrous, autooxidizable carrier while fertilized eggs have an active cytochrome system, the present data would suggest that the scarlatinal toxin reacts in some way with the cytochrome system. Confirmation of this suggestion was obtained from experiments involving chicken erythrocytes and the respiratory carriers, pyocyanine and methylene blue. The rate of O₂ consumption of control chicken erythrocytes was increased slightly by the addition of pyocyanine or methylene blue while the rate of respiration of erythrocytes which had been inhibited by the toxin was accelerated to the same level as the controls by the addition of these carriers. These experiments demonstrate that the toxins of *Str. pyogenes* inhibit the respiration of several different types of cells by reacting with the cytochrome system.

Electrical and functional activity of spinal motor neurons. JOHN HUNTER, RICHARD LILLIE (by invitation), and ROBERT GESELL. *Dept of Physiology, Univ of Michigan, Ann Arbor, Mich.* The ventral root of the phrenic nerve of the dog exhibits two characteristic types of electrical activity. 1) slow periodic waves which increase and decrease in negativity with inspiration and expiration respectively, and 2) quick potential changes superimposed upon the inspiratory fraction of the slow waves. The slow potentials diminish in magnitude with distance from the cord and are thus concluded to spread from the cord by electrotonus. The quick potentials suffer no decrement and are concluded to represent the inspiratory action potentials. Continuing unbroken electrotonic activity in the phrenic root indicates that the dendrites and cell body are always negative with respect to the neuraxon and that neurocellular currents consequently circulate between dendrites and neuraxon via internal and external circuits. Waving and waning of this continuing current produces periodic changes of intensity of the slow electrotonic component in the phrenic root. Rise of negativity of the slow component is attended by increasing numbers of action potentials. Sporadically and artificially increased depth of inspiration are attended by increased magnitude of the electrotonic component and by correspondingly increased numbers of action potentials. It is postulated that the current circulating between the dendrites and neuraxon generates nerve impulses at or in the proximity of the axon hillock. The current is therefore designated

'generating current'. It is suggested that our concept of specialization of function of the neuron questions the need of retaining the theory of synaptic transmission of nerve impulses and subsequent conduction along dendrites and cell body.

Proprioception and convulsions. J. HYDE, J. GAY and E. GELHORN. *Laby of Neurophysiology, Dept of Physiology, Univ of Minnesota, Minneapolis, Minn.* The influence of proprioceptive impulses on cortically induced afterdischarge and on chemically induced convulsions has been studied on cats and monkeys (*Macacus Rhesus*) in dial anesthesia. Fixation of a joint so as to prevent shortening of a muscle during contraction leads to an increased afterdischarge as well as increased amplitude of EMG in response to a standard cortical stimulus. In contrast to this proprioceptive facilitation of afterdischarge, removal of proprioception by appropriate posterior root section decreases afterdischarge and in some cases qualitatively changes it from a tonic to a clonic form. Afferent proprioceptive impulses induced by stimulation of the peripheral end of the motor root S₁ have been seen to alter convulsive spikes induced by topical application of strychnine on the cortex. The effect is largely confined to the contralateral sensori-motor cortex and is greater in the hindleg than in the foreleg and face area. It consists in either increase or decrease in frequency of the strychnine potentials. Finally, convulsive movements induced by applying strychnine to the exposed dorsal columns of the cord are reduced or eliminated by deafferentation although not significantly altered by removal of cutaneous impulses. The experiments furnish evidence for the fact that convulsive potentials and movements are greatly influenced by proprioceptive impulses.

Determination of cardiac output by an improved electrical conductivity method. RAYMOND C. INGRAHAM. *Dept of Physiology, Univ of Illinois, College of Medicine, Chicago, Ill.* Basically the present method follows H. L. White's recent modification rather closely. A small quantity of hypertonic salt solution is injected as rapidly as possible into the right atrium. Conductivity changes are recorded in blood flowing through a specially designed conductivity cannula tied in a peripheral artery. The output of the bridge, of which the conductivity cannula constitutes one arm, is amplified, rectified and then recorded by the deflection of a suitable sensitive reflecting galvanometer. The degree of bridge imbalance is optically recorded and later translated to concentration changes of sodium chloride by the construction of a calibration curve. The improvements in the present method are essentially in the design of all constituent parts so that it accomplishes the desired purpose to a degree consistent with modern

electronic methods. Comparison of cardiac output as determined by this method in the intact animal with the direct Fick and dye injection method has yielded results that compare very favorably. Determinations were made simultaneously. It was found that the improved design required the use of a smaller amount of a more dilute solution of sodium chloride than previous applications of this method have required. This minimizes the error due to salt loss in passage through the lungs. Recirculation can be recognized, if it occurs, and corrections made. This method thus allows for continuous recording of cardiac output data and also simultaneous optical recordings of pressure variations in any accessible portion of the cardio-vascular system.

Dynamics of evaporative heat loss for a rapidly cooling human body TOHRU INOUE (by invitation), NATHANIEL GLICKMAN, and ROBERT W. KEETON. *Dept of Medicine, Univ of Illinois, Chicago, Ill.* The dynamics of evaporative heat loss for a rapidly cooling human body in a 'comfortable' environment after having been exposed to a hot environment was studied on 6 healthy young men. The subjects were clothed in 90% cotton union suits containing variable amounts of moisture accumulated as a result of 1 or 2-hour exposures to a hot environment. The hot room was maintained at 37°C with a water vapor pressure of 41.1×10^3 dynes/cm² and the 'comfortable' room at 24°C with water vapor pressures of 9.1×10^3 , 18.2×10^3 , and 24.3×10^3 dynes/cm² with air velocity minimal and constant. Observations included weight loss and skin temperatures obtained at short intervals for 1 hour. The equation governing evaporative heat loss was theoretically derived for the dynamic state. Hitherto, this was applied only on subjects in approximate equilibrium with the environment with the introduction of wettedness as a calculated factor to account for an indeterminate variable. Under dynamic conditions, available moisture in the union suit and on the skin was found to adequately express wettedness. The inclusion in the equation of the amount of available moisture yielded a linear correlation for each of the 36 tests with an average correlation coefficient of 0.992. Thus, for subjects under rapidly changing physiological conditions, the amount of evaporative heat loss was proportional to the gradient of water vapor pressure between the skin and the ambient environment, amount of available moisture on the skin and in the union suit, surface area and time.

Developmental relationships between electrical activity and histogenesis of the cerebellum JOHN JACOBS and RAY S. SNIDER (introduced by H. W. MAGOUN). *Depts of Pathology and Anatomy, Northwestern Univ Medical School, Chicago, Ill.*

Correlation studies have been made between the first appearance of the fast intrinsic spontaneous electrical activity in the cerebellum of the newborn and the histogenesis of the cerebellar cortex. Anesthetized or acutely decerebrated newborn guinea pigs and rats between 1 and 28 days, as well as rat fetuses, were used. A complete comparative neuro-electrogenetic study on reptiles, avians and mammals, including primates, is in progress. Electrical activity was visualized and photographed from a cathode ray tube after amplification through a Grass Model III amplifier. Both bipolar and monopolar silver wire and cotton wick electrodes were used. For histogenetic studies silver, Nissl, Golgi and Feulgen (for thymonucleic acid) stains were used on Purkinje, granule and basket cells. Typical cerebellar electrical activity of 10-60 microvolts with a frequency of 150-250/sec first appears about the 12th day postpartum in the rat and is present in the newborn guinea pig. Several histogenetic changes take place in the cerebellum of the rat about the 12th day: 1) connections of the granule cell glomerulus are established, 2) nuclear chromatin of the Purkinje cell first appears Feulgen positive, 3) Purkinje cell nucleolus shows a trace of thymonucleic acid, 4) cytoplasm of the Purkinje cell is Feulgen negative but gives a positive Nissl reaction as early as 10 days. Granule cells are Feulgen positive as early as 9 days. Data are not complete on basket cells.

Antihemolytic action of a hemolytic agent M. H. JACOBS, MARIAN WILLIS LEFEVRE (by invitation) and CAROLYN STOUT (by invitation). *Dept of Physiology, Univ of Pennsylvania, Philadelphia, Penna.* Sodium oleate shows a notoriously complex relation between concentration and hemolytic activity and according to circumstances increasing its concentration may either increase or decrease the rate of hemolysis. This and other complications are due, at least in part, to the co-existence of a hemolytic and an antihemolytic effect of the oleate. The hemolytic effect has the general characteristics of an induced cation permeability, as shown by shrinkage of the cells in isosmotic sucrose, protection by low concentrations of sucrose, rapid return of volume after shrinkage by concentrated NaCl and swelling in alkaline solutions. This effect, which increases with concentration, is more or less disguised by the antihemolytic effect, which also increases with concentration and seems to be due to the prevention by oleate at the cell surface either of swelling of the cells or escape of hemoglobin, or both. The antihemolytic effect is well shown in photographically recorded hemolysis curves. If during hemolysis by weak oleate, more oleate is suddenly added the process may instantly, though temporarily, be stopped. Osmotic hemolysis may similarly be

checked. Conversely, removal of protective oleate by appropriate dilution with isotonic NaCl causes immediate hemolysis, provided that the initial exposure has been sufficient to render the cells cation permeable. A more striking way of showing the same thing is by the addition of washed normal erythrocytes to a suspension of other erythrocytes that have been altered but simultaneously protected by oleate, under properly chosen conditions hemolysis of the treated cells then immediately occurs.

Influence of niacin on the excretion of ketone bodies in normal fasted rats R. G. JANES and J. BRADY (by invitation) *Dept. of Anatomy, State Univ. of Iowa, Iowa City, Ia.* In previous experiments we have shown that relatively large amounts of niacin will produce a ketonuria in severely diabetic male rats. In the present study it has been found that the daily administration of 35 mg of niacin to normal female rats was ineffective in altering acetone body excretion. However, if female rats were given daily intraperitoneal injections of niacin during a 5-day fasting period, a marked ketonuria occurred. Control fasted rats receiving injections of physiological saline failed to show a pathological level of ketone body excretion. Niacin has been given to rats at levels of 5, 20, 35 or 50 mg per day. All of these animals showed greater acetone body excretion levels than control rats but the 35- and 50-mg dosages appeared to produce a more marked ketogenic response although some variation was seen in each group.

Regulation of food intake in normal and esophagostomized dogs HENRY D. JANOWITZ (by invitation) and M. I. GROSSMAN *Dept. of Clinical Science, Univ. of Illinois College of Medicine, Chicago, Ill.* Factors concerned in regulating intake of food were investigated in dogs by noting 1) effects of intragastric feeding on normal feeding in dogs with gastric fistulas, 2) effects of real and sham feeding on eating time in dogs with esophagostomies and 3) effects of oral supplementary prefeeding on food intake in intact animals.

Under standardized conditions, intragastric feeding of 50% or more of the average daily meal had an immediate significant but not equivalent depressing effect on oral food intake. If time was allowed for gastric evacuation (4 hours) the feeding had no such inhibitory effect. Division of the exteriorized esophagus in otherwise normal dogs led to immediate significant prolongation of eating time. Satiety conferred by sham feeding was of short duration, usually less than two hours. Beyond this point, increasing food deprivation or lengthening intervals between sham feeding did not increase the duration of sham feeding. Intragastric feeding and absorption of such feeding (up to 4 hours) had no inhibitory effect on sham feeding time. Sham

feeding time was shortened but not reduced to normal by simultaneous sham and intragastric feeding. Gastric distention by balloon reduced sham feeding time only when obvious nausea was induced. The oral prefeeding of a fraction of the daily meal reduced food intake by a corresponding amount in intact animals.

These studies disclose two sets of factors which under these standardized conditions influence regulation of intake of food: 1) oral factors ('gustatory satiety') and 2) gastric distention factors, which to be effective must act simultaneously with the oral factors.

Action of Phenylindanedione on prothrombin time L. B. JAKES, E. TAYLOR (by invitation) and E. LEPP (by invitation) *Dept. of Physiology, Univ. of Saskatchewan, Saskatoon, Sask., Canada.* Meunier, Mentzer and Molho (*Compt. rend. Acad. sc.* 224: 1666, 1947) have reported that 2-phenyl indane dione-1,3 (PID) is a more rapidly acting prothrombopenic agent than dicumarol. The effect of PID on prothrombin time was tested in dogs and rabbits. Single doses showed a rapid but slight effect on prothrombin time. Repeated administration of the drug at frequent intervals caused a marked effect on the prothrombin time. 8.3 mg/kg every 8 hours gave a prothrombin time of infinity, 1 mg/kg/8 hours doubled the prothrombin time. Withdrawal of PID caused the prothrombin time to return to normal within 36 hours. Vitamin K had no effect on the action of PID.

The prolonged prothrombin time following administration of PID was accompanied by a normal concentration of prothrombin in the blood but there occurred a very marked diminution in Factor V activity (Owren). The concentration of Factor V itself was not reduced, suggesting the presence of an inhibitor of Factor V. PID itself had little effect on the components of the clotting system. Large doses of the drug over a long period of time plus other factors produced a hemorrhagic condition similar to that of dicumarol overdosage. Withdrawal of the drug rapidly reversed this condition. No toxic effects were observed with 8.3 mg/kg given every 8 hours for 48 days to dogs. The PID was excreted by the kidneys.

Studies on 'dumping syndrome' in the dog following anastomotic operations and vagotomy N. C. JEFFERSON (by invitation), C. W. PHILLIPS (by invitation), R. LEVINE and H. NECHLES *Dept. of Gastrointestinal Research, Medical Research Inst., Michael Reese Hospital, Chicago, Ill.* Following a study on patients suffering from the so-called dumping syndrome after subtotal gastrectomy (*Gastroenterol.* Feb. 1949), the present study on dogs was done in order to obtain more controlled conditions. Intravenous and oral glucose and fructose tolerance tests were performed before and

after operation, and in some tests emptying time was determined with the barium meal. The following anastomotic operations were done: Polya, Hofmeister, gastro-enterostomy, pyloro-plasty, entero-enterostomy and additional vagotomies. The following results were obtained: in no normal control dog did hypoglycemia develop with any of the tolerance tests. In none of the operated animals did the tolerance test evoke hypoglycemia. Subsequent to anastomotic operations the oral glucose tolerance curve showed a persistent increase in height and duration. In most animals in which bilateral transthoracic vagotomy was performed with or subsequent to anastomotic operations, the oral glucose tolerance curve showed an additional increase in blood sugar levels. Oral glucose tolerance tests on 2 dogs with subtotal gastrectomy held in the upright position during the test revealed increased height of the glucose tolerance curve. In 2 animals with anastomotic operations in whom following vagotomy an increased glucose tolerance curve occurred, atrophy of the pancreas was found at autopsy.

Further studies on electrical analogs of the circulatory system KENNETH E. JOCHIM, *Dept of Physiology, Univ of Kansas, Lawrence, Kansas*. In a previous report simplified electrical analogs of the circulatory system were described, and results of an analytical and experimental study of their behavior were presented. These circuits consisted of single or multiple mesh networks which were energized with half sine wave current pulses, and in which the distensibility of the arterial system was represented by one or more parallel condensers.

This study was extended by introducing two additional complications which simulated more closely the conditions in the circulatory system: 1) the networks were energized with current pulses of various wave-forms, and for each one it was shown, experimentally and analytically, that the ratio of pulse volume, or maximum arterial uptake, to stroke volume (using hemodynamic terminology) fell between 0.50 and 0.56 over a wide range of values of the circuit parameters. A graphical method was evolved for computing this ratio for any input wave-form, whether its equation is known or not. 2) It has been shown by Hamilton and by the author that the distensibility curves of rubber tubes and arterial segments depend on the rate of change and direction of change of applied tension. This type of distensibility variation was simulated electrically and its effect on the pulse volume/stroke volume ratio was shown, analytically and experimentally, to be insignificant within certain limits.

Cause of injury in rapid deceleration MILTON JOFFE (by invitation) and FRED A. HITCHCOCK, *Dept of Physiology, Ohio State Univ, Columbus,*

Ohio. Experiments have been carried out on cadavers and anesthetized dogs to determine the effects of rapid deceleration. Acceleration was accomplished by falling weights attached by a steel cable to the lower extremity of the test body. Rapid deceleration was produced by a safety harness attached around the waist and connected by means of a tail line to the cross member of a T-shaped channel iron frame. The G forces produced were recorded photographically from vacuum tube type accelerometers. The decelerative forces were less than those expected from calculation, which was probably due to the lack of rigidity in the tube attachments. It was observed that there was no damping effect of tissues on the transmission of forces from the belt to the heart.

Seven dogs were subjected to multiple decelerations. Serial electrocardiograms were made on all dogs over a period ranging up to 9 days or until death. Autopsies were performed at death. Results of serial electrocardiograms on dogs showed inversions or other abnormalities of the T-wave in one or more of the 3 standard leads. X-ray heart shadow in one case, autopsy in all 7 cases, showed a dilatation of the heart with thinning of right ventricular wall. Four of 7 dogs also showed pulmonary, hepatic or renal vascular engorgement. The findings pointed to a condition of right heart failure—the traumatic heart injury syndrome.

Influence of hydrostatic pressure and of urethan on the thermal inactivation rate of bacteriophage FRANK H. JOHNSON and RUTH A. C. FOSTER (by invitation), *Biological Lab, Princeton Univ, Princeton, N. J.* The activity of *Escherichia coli* bacteriophages T-1, T-2, T-5 and T-7 is destroyed at 60 to 68°C in nutrient broth, pH 6.6, at rates which change with time during the exposure to heat. Addition of 0.005 M MgCl₂ retards the rate of destruction of infective centers of T-1, T-2, T-5, but not of T-7, and results in a first order rate of destruction of T-5. Urethan in concentrations of 0.05 to 0.5 M accelerates the rate of thermal destruction of all 4 of these bacteriophages. Increased hydrostatic pressure, up to 10,000 lb p s i, retards the rate of thermal inactivation of T-1, T-2, and T-5, but slightly accelerates that of T-7. In presence of urethan, pressure opposes the rate of destruction of T-5 but has little effect on that of T-7.

An intact mammalian muscle preparation for use in studies on respiratory metabolism SHIRLEY A. JOHNSON (by invitation) and KENNETH C. FISHER, *Univ of Toronto, Toronto, Canada*. An examination of the properties of the isolated rat diaphragm lead to the conclusion that this preparation is far from representing normal resting muscle. We have therefore given consideration to other, possibly more normal, preparations. It has been found that the

extensor digitorum longus from the lower leg of 50 to 70-gm rats is a very satisfactory preparation. At 30°C it always remains excitable for at least 6-8 hours, and in pure oxygen the rate of diffusion of oxygen into the preparation is sufficient to maintain the normal rates of consumption. Though this muscle appears to be more satisfactory for use than is the diaphragm, even it is probably not strictly resting tissue.

Suppression of urinary chorionic gonadotrophin, symptoms and pulmonary metastases in chorion-epithelioma by diethylstilbestrol EDWIN C JUNGCK (by invitation), WILLIAM O MADDOCK (by invitation), CLIFFORD L FEARL (by invitation), and CARL G HELLER *Depts of Physiology, Gynecology and Medicine, Univ of Oregon Med School, Portland, Oregon*. Large doses of stilbestrol are effective in suppressing anterior pituitary gonadotrophin secretion in post-menopausal and castrated women. Therefore, stilbestrol was administered to a 28-year-old woman with pulmonary metastases from a uterine chorionepithelioma, in hope of similarly depressing the gonadotrophins of chorionic origin, and with the vague hope that suppression of function might be accompanied by morphological regression of the malignant cells. At the time the primary tumor was removed (total utero-salpingo-oophorectomy), no pulmonary metastases were visualized. Four months later, multiple pulmonary lesions characteristic of metastatic chorionepithelioma were noted along with weight loss, asthenia and hemoptysis. Six months after operation, urinary excretion of chorionic gonadotrophin was 3200 IU/24 hours. After 4 weeks of daily intramuscular injections of 10 mg of stilbestrol in oil, chorionic gonadotrophin excretion dropped to 640 IU, symptoms disappeared and pulmonary metastases were regressing. In 9 weeks, hormone titers were 6-16 IU/24 hours and remained at that level as long as daily injections were continued, radiological evidence of pulmonary metastases was no longer present. Stilbestrol, 10 mg in water suspension, was as effective as the oil preparation when given intramuscularly. After 6½ months, 25 mg stilbestrol daily by mouth was substituted for the injections. A slight rise in titer was observed, which disappeared when the dose was increased to 50 mg daily by mouth.

The above findings could be due to coincidence, however, they suggest that 1) stilbestrol may inhibit chorionic as well as pituitary gonadotrophins and 2) morphological and functional regression may accompany each other when stilbestrol is administered in chorionepithelioma.

Site of action of myanesin (tolserol) in the central nervous system B R KAADA (introduced by JOHN F FULTON) *Laby of Physiology, Yale Univ School of Medicine, New Haven, Conn*

Following the announcement of the muscular relaxation effect of Myanesin (3-ortho-tolonyl-1,2-Propanediol) by Berger and Bradley in 1946 there has been marked interest in the potential value of this drug as an adjuvant to anesthesia and in the treatment of neuro-muscular disorders such as rigidity, spasticity, muscle spasm and involuntary movements. The site of action of this drug, particularly in clinical doses (20-30 mg/kg), is as yet unknown. With such doses of Myanesin it has been confirmed that hyperirritable spinal reflexes (in our study experimentally produced in cats and monkeys under light chloralose anesthesia, by injection of prostigmine and strychnine) can be reduced, but are without any effect on normal reflexes. In the present study it has been shown that at higher dosage (40-50 mg/kg, i.v.) the multi-neuron reflex discharges are depressed before the two-neuron ones, and correspondingly flexion and crossed extension reflexes are depressed earlier than the knee jerk. In spinal animals strychnine increases predominantly the multineuron reflex discharge, which can be reduced to normal promptly with Myanesin. Complete inhibition of strychnine convulsions has also been obtained from electrical stimulation of the bulbo-reticular suppressor region and facilitation of subconvulsive doses from the facilitatory region. The multi-neuron discharges can be inhibited or facilitated at lower stimulus intensities than the two-neuron reflex discharge from these regions. The threshold for obtaining suppression or facilitation of spinal reflexes from stimulation of the bulbar suppressor and facilitatory centers was measured before and after the administration of clinical doses of Myanesin. The threshold was found decreased for the suppressor and increased for the facilitatory stimuli, indicating that Myanesin in some way affects the balance between inhibitory and facilitatory impulses playing upon the spinal neurons in favor of the former. The possibility that Myanesin at least partly may act via or on the same structures as the suppressor or facilitatory systems is suggested.

Respiratory and vascular responses in monkeys from temporal pole, insula, orbital surface and cingulate B R KAADA, K H PRIBRAM and J A EPSTEIN (introduced by JOHN F FULTON) *Laby of Physiology, Yale Univ School of Medicine, New Haven, Conn*. The results of electrical stimulation of the cortex of the temporal and frontal lobes and the insula of monkey with recording of vascular and respiratory responses are reported. Square wave pulses of low intensity (3-8 volts) and of varying frequency and pulse duration were used. From the temporal pole blood pressure alterations and respiratory inhibition were obtained.

The optimal parameters of stimulation were found to be a frequency of about 40/sec and long pulse durations (10 msec). With these optimal parameters similar vascular and respiratory responses were obtained from a continuous cortical region extending through the anterior insula, the posterior orbital surface of the frontal lobe, the subcallosal region to the rostral limbic gyrus and also including basal olfactory structures (uncus, limen insulae, anterior perforated space). The lateral surface of the frontal lobe including the depths of the arcuate and principal sulci were explored, but only inconsistent respiratory changes were obtained from the cortex dorsal to the superior limb of the arcuate sulcus and ventral to its inferior limb. The continuous responsive region is covered either by allocortex or by agranular or sparsely granular isocortex showing some characteristics of the nearness of allocortex. The relevant connections of these areas are discussed.

Radioactive diiodotyrosine in studies of thyroidal and tissue organic iodine GOPAL KARANDIKAR (introduced by WILLIAM T. SALTER) *Dept of Pharmacology, Yale Univ School of Medicine, New Haven, Conn.* All mammalian tissues contain organic iodine (so-called 'thyrenzyme'), except when hypothyroidism follows thyroidectomy or prolonged treatment with a goitrogen. When radioactive iodide is administered, the thyroid gland forms radioactive diiodotyrosine, later the organic iodine in peripheral tissues increases while the radioactive iodide declines. After the administration of radioactive diiodotyrosine intraperitoneally to rats (both normal and goitrous), part of the ensuing changes in iodine metabolism is due to iodide originating from decomposed diiodotyrosine. This feature is dependent quantitatively upon the dosage employed, because in larger dosage relatively less diiodotyrosine is de-iodinated. Both thyroid gland and peripheral tissue share in the newly acquired iodine. In less than an hour after diiodotyrosine is injected the total iodine in peripheral tissues increases. Besides iodide, diiodotyrosine contributes to the increase, but in the early stages its association with protein fractions is largely by adsorption. Eventually some of the newly acquired iodine is incorporated in the tissue protein (e.g., muscle, liver), although the distribution is not uniform throughout the several muscle protein fractions. In the building up of the genuine ('thyrenzyme') peripheral protein-bound iodine the thyroid gland plays an important role, which is influenced by goitrogenic substances.

Bile action on the volume and content of gastric juice in triple histamine experiments JERZY KAULBERSZ and RYSZARD BILSKI *Dept of Physiology, Jagellonian University, Cracow, Poland.* This study is a continuation of previous work done

at Wayne Univ College of Medicine by one of us (J. K.), which revealed in single histamine experiments (*Federation Proc* 1:45, 1942) that bile increases the secretion from the Pavlov pouches and gastric fistulas, while it seemed to have little if any effect on the secretion from the Heidenhain pouches. Beamer, Friedman, Thomas and Rehfuess (*Federation Proc* 3:3, 1944) noted that bile introduced into the stomachs of dogs with fistula results in a secretion of gastric juice, and instilled directly into the intestine it increases the gastric secretory response to proteoses.

In the present investigation a triple histamine method on dogs with Heidenhain pouches was employed, with one bile plus histamine and two histamine control tests on each day of the experiment. The total output of HCl and peptic power was determined. When histamine alone was administered 3 times a day in 24 experiments the average mEq of the first and third periods were identical, those of the second period 5% lower. Bile solution (5-10% ox bile) was introduced through a gastric tube in 54 triple histamine experiments, 18 times in each period. It evoked an increase of the volume of secretion from the Heidenhain pouches, affecting only slightly the acidity and the peptic power. The average mEq were 16-27% higher than those of the controls. Bile also exerts in dogs with Heidenhain pouches a slight stimulatory effect on the gastric secretion after histamine, which may not be easy to detect in single histamine experiments because of the daily variations in the HCl output. In cases of hypersecretion, the regurgitation of bile into the stomach may present a source of continuous stimulation.

Functional disturbances and their compensation following circumscribed lesions of the vestibular nuclei S. R. KEMBERLING (by invitation) and E. A. SPIEGEL *Depts of Exptl Neurology and of Pediatrics, Temple Univ School of Medicine and Hospital, Philadelphia, Penna.* Circumscribed lesions of the left vestibular nuclei (VN) were produced in 46 cats, in 29 the symptomatology was studied up to 5 months. Definite vestibular symptoms developed in 5 cats without abnormal head posture. In 4 others torticollis remained the only symptom except for slight homolateral hypotonia demonstrable by measurements only. The localizing value of this dissociation remains to be analyzed histologically. Postrotatory nystagmus tested in 12 cats showed no disturbance in one, reduction to left in 5, transitory loss to left and replacement by a few jerks to right in 2 (appearance of latent spontaneous nystagmus to right?). Definite compensatory phenomena as observed following labyrinthectomy (Ruttin) were absent. In 4 cases induced nystagmus to left was increased (effect of

latent tendency toward spontaneous nystagmus to left?) Residual slight reduction of extensor tone could be demonstrated only by measurements in 3 cats. Despite incomplete recovery of tone, decerebration could produce definite extensor rigidity of the forelimbs. Following decerebration there was in 3 cats no or only minimal difference of posture of the forelegs with slightly diminished extensor tone demonstrable by measurements only. In one cat measurements failed to reveal differences of left and rightsided extensor tone. In one instance maximum extensor tone (elbow) was higher on the operated side and twice extension was more pronounced in the left than the right hindleg (apparently overcompensation). The experiments point to the importance of the reticulate substance besides the V N for maintenance of tonus (Spiegel and Bernis, *Arbeiten Neurol. Inst. Vienna*, 1925).

Effect of oxygen administration on the survival of dogs explosively decompressed to 30 mm Hg. JOHN P. KEMPH (by invitation) and F. A. HITCHCOCK, *Dept. of Physiology, Ohio State University, Columbus, Ohio*. It has previously been reported from this laboratory that dogs survive exposure to a barometric pressure of 30 mm Hg for not more than 2 minutes. A series of experiments has been carried out in which oxygen was administered by insufflation to dogs explosively decompressed to this pressure. These dogs usually survived exposures of 3 minutes to this pressure. Insufflation was begun immediately after explosive decompression and continued until after the animal was returned to atmospheric pressure. Immediately upon recompression there was a bradycardia. The heart rate then gradually increased to a tachycardia, followed by a gradual decrease to a normal rate. Spontaneous respiration began about 60 seconds after insufflation was stopped. Occasionally animals survived 2 such explosions. In the animals which did not survive 3-minute exposures, several spasmodic ventricular beats were noted and autopsy occasionally showed the auricles to be contracting rhythmically. It is believed that this procedure is beneficial in two ways: 1) the pO_2 of alveolar air is increased and 2) the intrapulmonary pressure is maintained at a level sufficient to prevent the rapid evaporation of body fluids and to delay the formation of intravascular bubbles.

Influence of hesperidin methyl chalcone on the action of cardiac, striated and smooth muscles. W. JOHN KENFIELD and DAVID F. BOHR (introduced by ROBERT GESEIL), *Dept. of Physiology, Univ. of Michigan, Ann Arbor, Mich.* Observations have been made to determine the effects of hesperidin methyl chalcone (HMC) on the action of various isolated muscle tissues. One of the primary goals of this study has been to determine if the drug

has any activity as a general protoplasmic toxin. The influence of HMC on the isolated sartorius muscle of the frog was studied by comparing the shape of its fatigue curves obtained in the presence of HMC with the shape of control fatigue curves. The presence of 0.2 mg HMC per cc in the Ringer's bath did not change the shape of the fatigue curves. A study was made of the amplitude of contraction of the turtle's ventricle perfused with Ringer's solution containing various concentrations of HMC. No decrease in amplitude of contraction was observed with concentrations varying from 0.02 mg per cc to 0.2 mg per cc. The influence of HMC on the activity of smooth muscle was studied by observing its effects on isolated longitudinal muscle of the rabbit duodenum. In concentrations varying from 0.01 to 2.0 mg/cc of Tyrode's solution, HMC caused a decrease in both muscle tone and amplitude of intrinsic rhythmic contractions. These changes were completely reversible. Although definite changes in the physiological activity of smooth muscle were observed, no evidence was obtained to indicate that HMC has a toxic effect on isolated tissues.

Factors influencing the demonstration of renal tubular potassium secretion in the normal dog. THOMAS J. KENNEDY, JR., JAMES G. HILTON, and ROBERT W. BERLINER (introduced by JAMES A. SHANNON), *Research Service, First (Columbia Univ.) Division, Goldwater Memorial Hospital, and the Dept. of Medicine, College of Physicians and Surgeons, Columbia University, New York City*. Evidence of renal tubular secretion of potassium has been previously presented (Berliner and Kennedy, *Proc. Soc. Exptl. Biol. & Med.* 67:542, 1948; Mudge, Foulks and Gilman, *Ibid.*, p. 545). Experiments involving infusion of K salts have been done on 10 normal dogs. Excreted potassium was compared with filtered potassium, estimated as the product of plasma K and glomerular filtration rate. The latter was measured as the clearance of creatinine, inulin, or thiosulfate which, measured simultaneously, give identical results under the circumstances of these studies. Direct evidence of secretion, manifested by an excess of excreted over filtered K, has been obtained in all 10 dogs. In only one of 8 dogs could this be demonstrated without previous oral administration of K salts. Even in K-tolerant dogs there are considerable individual differences in the magnitude of the excess of excreted over filtered K. The ratio of excreted to filtered is a function of the anion with which K is infused—non-reabsorbable anions such as thiosulfate or ferrocyanide give considerably higher ratios than chloride. Within the range of plasma K safely attainable, there is no evidence of depression of the ratio of excreted to filtered as the rate of infusion of K is increased.

Sub-estrous response to dietary restriction and reversal in castrate C3H mice JOSEPH T. KING, CARMEN B. CASAS (by invitation) and M. B. VISSCHER *Dept of Physiology, Univ of Minnesota, Minneapolis, Minn* The sub-estrous response seen in certain strains of ovariectomized mice when fed *ad libitum* can be inhibited by restricting the caloric intake to about 66% of normal (Casas, King and Visscher, *Federation Proc*, 6: 87, 1947). Groups of 10 or more C3H mice, ovariectomized at 19-21 days of age, have been studied to determine the estrous response to full feeding after periods of restriction from 1 to 6 months; other groups were reversed from full feeding to restriction at periods up to 4 months. Control groups always full fed or always restricted were also studied. Restriction was to about 66% of the calories eaten by controls fed *ad libitum*; the absolute amounts of protein, salts and vitamins were essentially the same as taken by the control group. Smears were taken by the lavage method. In general restricted mice developed dense, mixed smears in 4-12 weeks after reversal to *ad libitum* feeding; there is considerable individual variation in the time required to develop a positive smear. Mice placed on restriction after full feeding show a positive smear for 2-5 months. If the period of full feeding is not longer than 1 month the mice usually remain in anestrus. Related weight changes are discussed.

Mixing rate within the mobile phosphate pool of cows MAX KLEIBER, A. H. SMITH (by invitation), N. P. RALSTON (by invitation) and D. E. JASPER (by invitation) *College of Agriculture, Univ of California, Davis, Calif* Intravenous injection of P^{32} into cows allowed the measurement of turnover rates for various processes of phosphate transfer. These rates characterize the mobility of the phosphate pool. The turnover time for mixing the mobile phosphate in blood with that of the extracellular tissue fluid of the cow is of the order of 10 minutes.

Procedure for the *in vitro* study of hormonal influences in nitrogen metabolism DANIEL L. KLINE (introduced by JANE A. RUSSELL) *Dept of Physiological Chemistry, Yale Univ School of Medicine, New Haven, Conn* Rat diaphragm and liver slices were incubated in 4 cc of Krebs-Ringer-bicarbonate solution at 38°C and the nitrogen which appeared in the medium was determined at 15 and 195 minutes. To obtain results which were consistent and biologically meaningful, it was necessary to centrifuge from the medium fragments which separated from the tissues during incubation. The N which appeared in the medium during the first 15 minutes was non-metabolic in origin, arising chiefly as debris from slicing. This was shown by the failure of ionic, osmotic and temperature changes to affect the 15-minute value, whereas

cutting the tissue into more pieces of the same thickness increased this value. The output of N during a period of 3 hours after an initial 15-minute equilibration period is believed to be metabolic in origin since the rate of addition of N to the medium during this time was lessened by lowering the temperature of incubation and was increased by the exclusion of O_2 and the addition of iodoacetate to the medium.

For normal animals the addition of total N to the medium between 15 minutes and 195 minutes was 0.31 ± 0.01 mg/100 mg of wet diaphragm and 0.35 ± 0.02 mg/100 mg of wet liver slices. The amino N increment in the medium was 52 ± 3 mcgm/100 mg of diaphragm and 44 ± 2 mcgm/100 mg of liver. In hypophysectomized rats the increments of total N were 0.18 ± 0.02 mg/100 mg of diaphragm and 0.24 ± 0.03 mg/100 mg of liver. The amino N increments were 29 ± 2 mcgm/100 mg of diaphragm and 28 ± 2 mcgm/100 mg of liver. These values are significantly different from those obtained in the normal series.

Isolation of legcoproporphyrin HENRICH KLÜVER *Division of the Biological Sciences, Univ of Chicago, Chicago, Ill* In a study of the prophyrins in the root nodules of legumes we have found that the nodules of *Phaseolus vulgaris* (var Red Kidney bean) contain a porphyrin which appears to be characteristically different from previously described naturally occurring porphyrins. The absorption and fluorescence spectra of the free porphyrin and of its methyl ester as well as of various metal complexes are practically identical with those of coproporphyrin. As regards solubility, the legcoporphyrin behaves like the Waldenström type of uroporphyrin. It can be transferred from aqueous extracts to ethyl acetate at a pH of 3.2 to 3.5. The legcoporphyrin obtained from the nodules of plants 4-5 weeks old is chromatographically separable into two porphyrins on a $CaCO_3$ column. Different extraction procedures and rechromatography do not affect this separation into two porphyrins. It has not been possible to distinguish the two components spectroscopically. Our attempts at crystallizing the legcoporphyrin ester or its components have failed although we have succeeded in crystallizing the esters of protoporphyrin and mesoporphyrin derived from the heme compounds in the same nodules. Microscopic and microspectroscopic examinations of sections through root nodules under ultraviolet clearly indicate that the legcoporphyrin is confined to the cytoplasm of the infected cells. Future studies of symbiotic nitrogen fixation must consider not only the presence of leghemoglobin in the infected cells, but also the presence of such substances as legcoporphyrin. It is of further interest that the organs and body fluids of

porphyria patients may contain a porphyrin which seems to possess the characteristics of leucoporphyrin

Oximetric method for determination of the oxygen saturation of mixed venous blood in man JULIAN KNUTSON (by invitation), BOWEN E TAYLOR (by invitation), and EARL H WOOD *Section on Physiology, Mayo Foundation, Univ of Minnesota, Rochester, Minn* Arterial oxygen saturation was recorded continuously and simultaneously in 6 subjects by both the modified ear-piece oximeter and a whole-blood oximeter attached to an indwelling radial artery needle. The instrumental time lag was 2.5 and 2 seconds for the ear-piece and whole-blood oximeter, respectively. Both oximeters were calibrated against Van Slyke analyses of arterial samples obtained when each subject breathed air, 14% oxygen and 100% oxygen. The Matthes procedure as modified by Elam and co-workers was used. This consists of deep expiration followed first by a deep inspiration of helium and, second, expiration to mid-position followed by about 30 seconds of breath-holding.

After the inspiration of helium, the initial decrease in arterial saturation (circulation time) occurred at 4.5 (3-7) seconds at the ear and at 4.6 (4-6) seconds at the wrist. Saturation decreased 17 (13-23) % in 10 (6-15) seconds and then reached a plateau in 3 of the subjects, or decreased gradually in the remainder until 4.8 (3-7) seconds (ear) and 7.5 (4-10) seconds (wrist) after the inspiration of air. The average duration and saturation at the arterial plateau was 4 (3-5) seconds and 78 (77-79) % at the ear and 4 (3-6) seconds and 75 (75-79) % at the wrist. In the 3 subjects in whom an arterial plateau was obtained, the cardiac index calculated by the Fick principle (assuming the plateau value equalled the saturation of mixed venous blood) was 3.1 (2.6-3.5) L/M²/min. The contour of the changes in arterial oxygen saturation recorded photoelectrically at the ear and directly on the arterial blood at the wrist were similar in every instance, indicating that the ear oximeter can be used successfully for determination of the arterial saturation plateau by the Matthes procedure.

Function of the ear in health and disease (motion picture) H. G. KOBRAK, JOSEPH E. HIND (by invitation) and ROBERT B. MILLER (by invitation) *Univ of Chicago, Chicago, Ill*. The purpose of the film is to demonstrate the response of the ear to sound in health and disease. A method was developed at The University of Chicago by which it was possible to photograph the acoustic vibrations of the ear during the process of hearing. The method consists in proper optical magnification combined with stroboscopic illumination. The first part demonstrates the normal ear. Ear drum vibrations in response to sound stimulation are

shown. Movements of ossicular chain and the vibrations of the round window membrane are demonstrated. The phase difference between the movements of the stapes in the oval window and the round window membrane is visualized. Diseases of the middle ear are demonstrated on fresh temporal bones. Pathological function due to inflammatory adhesions and due to stapes fixation are demonstrated. Hearing curves of certain types of deafness are shown and the response of the ear demonstrated. By using electronic filters, the sound perception of a diseased ear is given in the sound track similar to the actual hearing defect. Therefore, the audience is able to see the pathologic function on the screen and simultaneously hear the distorted acoustic signal which the patient perceives. The action of hearing aids and intensity changes due to the action of the hearing aid is demonstrated. The acoustical vibrations of a surgical 'fenestra' in the lateral semicircular canal are demonstrated. In the final scene, the response of the ossicular chain to a piece of orchestral music is given.

Some factors influencing the contractile process SAUL R. KOREY (introduced by DAVID NACHMANSOHN) *Dept of Neurology, College of Physicians and Surgeons, Columbia Univ, New York City*. Investigations have been initiated to test factors which influence the contractile mechanism of the muscle fiber in contrast to those acting on the conductive mechanism. A most suitable material for studies on the contractile system are the muscle fibers prepared according to the method of Szent-Gyorgyi. In these fibers, kept in glycerol, conduction is abolished whereas contraction can be produced by ATP but not by electrical stimulation. Among a great number of chemical compounds tested, none were found to be able to produce contraction. This specificity of ATP supports Szent-Gyorgyi's assumption that the effect observed is basically identical with the physiological mechanism of contraction. Among the compounds which had no effect were adrenalin, acetylcholine and eserine. The activity of several enzymes in these fibers was studied, especially that of ATPase. Their relation to the contractile process will be discussed. The effect of some enzyme inhibitors was also investigated. Inhibitors of sulfhydryl groups abolish the effect of ATP. The action of these inhibitors was found to be reversible. The possible interpretation of this observation will be discussed.

Skin resistance patterns associated with visceral disease IRVING M. KORR *Kirkville College of Osteopathy and Surgery, Kirkville, Mo*. This abstract reports the results of a preliminary investigation of the part that visceral disease and irritations may play in determining the electrical

skin resistance patterns previously described (*Federation Proc* 7 67, 1948, and this issue) Two classes of patients having visceral disease have been explored with the dermohmmeter (Jasper) and found to have low-resistance areas (LRA) which not only showed segmental relation to the viscus involved, but were fairly consistent for a given disease entity and were related to the referred pain pattern Patients who had had myocardial infarcts had LRA over 2 or more of the upper 4 thoracic vertebrae, near the sternum at corresponding rib levels, and over the medial edges of one or both scapulae in the corresponding dermatomes In one subject, repeatedly examined over a period of months, such areas were first observed 3 weeks prior to a coronary occlusion Patients with duodenal cap ulcer had areas of markedly lowered resistance over the spinal muscles, on the right side, opposite vertebrae T-5 to T-8, over corresponding ribs on the anterior chest wall and to the right of the umbilicus In both diseases LRA appeared to coincide with or overlie the most painful or tender parts of the reference zone

Experimental alterations in segmental sympathetic (sweat gland) activity through myofascial and postural disturbances IRVIN M KORR, *Kirkville College of Osteopathy and Surgery, Kirkville, Mo* It was previously shown (*Federation Proc* 7 67, 1948) that patterns of electrical skin resistance over the trunk varied from individual to individual, but that areas of reduced resistance (hyperactive sweat glands), especially in or near the midline, remained relatively constant in each individual for weeks or months, the low-resistance areas (LRA) often showed a dermatomal distribution, were correlated in some subjects with reduced segmental motor reflex thresholds, overlay or adjoined areas of deep hyperesthesia, frequently showed 'trigger zone' characteristics Subsequent investigations have been directed at the factors related to or contributing to segmental sweat gland hyperactivity Dermohmmeter exploration of many subjects has shown the following 1) LRA occurred in segments in which there were known myofascial tenderness or rigidity, abnormal intervertebral relations, vertebral pathology, or other somatic or visceral irritations in the corresponding spinal segments 2) Clinical improvement was accompanied by elevation of the skin resistance and shrinking of LRA 3) Injection of 0.3 ml 6% NaCl into erector spinae or intercostal muscle caused appearance of LRA throughout the corresponding dermatomes (spine to sternum) which outlasted the referred pain by many hours 4) Experimental postural imbalance induced by wearing a 'lift' under one heel for several hours produced new LRA in the segments

in which pain and tenderness appeared, enlarged pre-existing LRA in other, often distant, segments and further reduced their resistance These observations support the hypothesis that myofascial and postural disturbances are accompanied by and may induce or maintain segmental hyperactivity in the sympathetic nervous system

Further studies on the effect of 'neurotripsy' on the partially denervated muscle of the dog A J KOSMAN and J N FREDERICK (introduced by J S GRAY) *Dept of Physiology, Northwestern Univ Medical School, Chicago, Ill* In a previous communication (*Proc Soc Exptl Biol & Med*, in press) we had reported that 'neurotripsy' (traumatic massage of a muscle) was ineffective in arresting the loss of strength and mass of the partially denervated anterior tibial muscle of the dog The present investigation was undertaken in order to determine the effect of the 'neurotripsy' procedure upon muscles subjected to a more extensive denervation and observed for a longer period of time Partial denervation of the anterior tibial muscles of 8 dogs was accomplished by the removal of the motor roots of L₅ and L₆ bilaterally Closed manual 'neurotripsy' was performed on the anterior tibial muscle of one side 3 months following the initial lesion and the animals were then sacrificed 4 months following the 'neurotripsy' At the time of death the mean tension and weight of the treated muscles were 2500 gm and 7.29 gm, respectively, and of the untreated muscles, 2250 gm and 6.77 gm respectively These differences are not statistically significant

The spleen as a blood reservoir during hypoxia KURT KRAMER and ULRICH C LUTZ (introduced by HARRY F ADLER) *Dept of Physiology, USAF School of Aviation Medicine, Randolph Field, Texas* The response of the spleen to different types of hypoxia was studied in 20 dogs under light nembutal anesthesia Continuous recordings were taken photoelectrically of arterial blood O₂ saturation and hemoglobin content The spleen was exposed without interfering with vascular and nervous attachments and its weight recorded with an electric balance Blood pressure tracings were taken by strain gage manometer In acute hypoxia induced by breathing pure nitrogen the spleen did not lose weight until the arterial O₂ saturation was approaching zero After that the organ contracted visibly and lost considerable weight Simultaneously the systemic hemoglobin content increased During recovery breathing air the spleen regained its initial size in about 20 minutes In less abrupt hypoxia using the rebreathing method two phases of splenic activity were observed Slow contraction commenced when the arterial O₂ saturation dropped below 40% Shortly before failure of respiration and after the asphyxial rise in blood pressure

the spleen discharged a large amount of blood as evidenced by a drop in weight of approximately 150 gm and a rise in circulating hemoglobin of 3 gm %. The inverse relationship between spleen weight and systemic hemoglobin was also observed during subsequent recovery when the excess hemoglobin disappeared while the spleen was refilling. In blood samples taken from the splenic vein during contraction hemoglobin concentration was 30-40 % higher than in arterial blood. Control animals in which the splenic vessels were ligated before the hypoxic episode showed no change of hemoglobin concentration in the general circulation.

Dark adaptation in lesions of the optic pathways HOWARD P. KRIEGER (by invitation) and MORRIS B. BENDER *Psychophysiological Lab., Dept. of Neurology, New York Univ. College of Medicine, New York City*. A study of the visual threshold for a luminous target, presented in a dark room, was made in patients with lesions of the optic pathways. These patients did not have disease of the retina. Preliminary perimetric studies, made under 7-foot candle illumination, revealed consistent defects in the fields of vision. Three patients had homonymous hemianopsias, a fourth an almost complete double hemianopsia and a fifth a temporal hemianopsia of the left eye. The machine used for testing was Wald's modification of the Hecht-Schlaer adaptometer. It was so altered that the source of light which acted as the target could be placed at any angle along any meridian in the subject's field of vision. All measurements were made on one eye at a time and in a dark room. Examination under these conditions disclosed that the luminous target was perceived by the patient in the apparently blind half-field. However, the final threshold in this region was about 500 times higher than in the corresponding normal region. Other significant findings were a great fluctuation in the threshold of the ability to see the target and a marked lag in the rate of dark adaptation. The patient with bilateral homonymous field defects showed similar changes in both fields of vision. The patient with the unilateral temporal field defect showed a change in the dark adaptation of the seemingly preserved temporal half. Parallel changes were found in other visual and sensory functions. In summary it was found 1) that patients with lesions of the optic pathways were able to see a luminous target, presented in the dark, in their fields of vision which were apparently blind upon perimetric examination and 2) that fields, apparently normal upon perimetric examination, may have changes in their dark adaptation process.

Control of early hypertension with dihydrogenated ergot derivatives and the physiological significance W. G. KUBICEK, F. J. KOTTKE AND

MILDRED E. OLSON (by invitation) *Dept. of Physical Medicine, Univ. of Minnesota, Minneapolis, Minn.* A significant reduction in arterial blood pressure was produced in young hypertensive patients following administration of dihydroergocornine methanesulfonate (DHO 180). A decrease of 10 to 20 mm Hg in diastolic pressure persisted for the duration of the drug therapy (2-3 weeks) and gradually increased to the control level after removal of the drug. Since DHO 180 is known to have sympathicolytic and adrenolytic actions the above observations indicate that sympathetic nervous system activity may contribute to the establishment of early hypertension. Renal clearance tests revealed normal kidney function in these patients.

Adsorption and fluorescence characteristics of crustacean sinus gland extracts ELOISE KUNTZ (introduced by IRWIN W. SIZER) *Arnold Biological Lab., Brown Univ., Providence, R. I.* The sinus glands of crustacea secrete one or more hormones which affect chromatophore activity, molting, oxygen consumption, phosphate metabolism, etc. Abramowitz (*J. Biol. Chem.* 132: 501, 1940) obtained a partially purified preparation which had the properties of a basic amine. This paper includes two methods of separation based on cation adsorption column techniques. An active principle is adsorbed by the sodium form of Amberlite IRC-50 at pH 5. It can be eluted with 0.1 N HCl. Another effective adsorbent is Folin-permutit which has been prewashed with 0.1% acetic acid. Elution is accomplished with 10% KCl. The strong fluorescence exhibited by the hormone in the oxidized form (maximum fluorescence with exciting light of 3450 Å) has been used to estimate the relative concentration of minute quantities of the purified sinus gland extract and can also be used to follow purification procedures. There is a linear relationship between concentration and intensity of fluorescence. The hormone is easily oxidized and reduced by mild redox systems. Glutathione oxidizes the reduced form. This oxidation is readily reversed by addition of sodium hydrosulfite to the hormone-glutathione mixture. Sodium hydrosulfite alone is ineffective in acid or neutral solutions but can reduce the oxidized form of the hormone in alkaline medium.

Mass spectrographic studies on expired and alveolar air GEORGE H. KING III (by invitation) and FRED A. HITCHCOCK *Dept. of Physiology, Ohio State University, Columbus, Ohio*. Studies made with the mass spectrograph developed in this laboratory for the continuous recording of the partial pressures of O₂ and CO₂ and already reported have shown that the pO₂, the pCO₂ and the RQ of alveolar air are all a function of the duration of exhalation. This work has been continued

and extended. In recent experiments maximal exhalations made in three seconds have been compared with similar exhalations lasting for 10 seconds or longer. In the longer exhalations the final pO_2 is always lower and the pCO_2 higher than in the shorter exhalations. The difference is often 10 mm or more. In the longer exhalations the curves of both the O_2 and the CO_2 approach a plateau although they do not completely level off. Calculations of the R/Q at one second intervals confirm the previous report of Hitchcock and Stacy that the quotient during the first second is high and tends to decrease as the exhalation progresses. The value of the R/Q toward the end of a maximal exhalation but not necessarily at the extreme end shows the best agreement with the R/Q of exhaled air.

Transition of fibrinogen to fibrin KOLOMAN LAKI (introduced by WILLIAM J. BOWEN) *Inst of Biochemistry, Budapest Laby of Physical Biology, Exptl Biology and Medicine Inst National Insts of Health, Bethesda, Md*. The transition of fibrinogen to fibrin, brought about by the action of thrombin, proceeds in 2 stages. Thrombin acting enzymatically is involved only in the first step, and its role is to modify the fibrinogen molecules. In the second step, the altered fibrinogen molecules polymerize to the fibrin clot. Iodination of fibrinogen results in preparations that do not polymerize any more but still respond to the action of thrombin with a shift in the isoelectric point. This shift very likely means that some acidic groups of the fibrinogen molecule are split off by thrombin. A difference between the acid-base titration curve of fibrinogen and that of fibrin shows that some groups of the fibrinogen molecules with a pK of about 9 are involved in the polymerization process. These could be either $-NH_2$ groups or the phenolic group of tyrosine. The polymerization is not simply an end-to-end association of the altered fibrinogen molecules. First these molecules polymerize to a unit with a particle weight of about 1.5 million and then these units, probably connected by electrostatic forces, build up the primary fibrils. In this respect, the polymerization of fibrinogen seems to be strikingly similar to the polymerization of actin, a protein of muscle fibril.

Attempt at direct measurement of values required for calculating the pulmonary diffusion coefficient for oxygen CHRISTIAN J. LAMBERTSEN, JOHN K. CLARK (by invitation), DOMINGO M. AVIADO, JR. (by invitation), ROBERT G. PONTIUS (by invitation), LARI S. BARKER (by invitation) and JOHN MOYER (by invitation) *Laby of Pharmacology, Univ of Pennsylvania, Philadelphia, Penna*. Simultaneous, direct measurements were made of alveolar, arterial blood and

mixed venous blood gas tensions and rate of O_2 consumption in a group of normal human subjects in an attempt to obtain data required for calculating of the pulmonary diffusion coefficient for oxygen. Subjects were studied while breathing air, 8% and 100% oxygen. The data obtained illustrated the important practical and theoretical difficulties to be expected in attempting direct measurement of the pulmonary diffusion coefficient for oxygen. The data provides values for alveolar and arterial O_2 tensions during the breathing of air, 8% and 100% oxygen, and a comparison of the several methods of alveolar gas tension determination employed. The removal of nitrogen from the lungs by 100% oxygen inhalation suggested the feasibility of using the end expiratory Haldane-Priestly sampling method to obtain a close approximation to mean alveolar pO_2 in subjects breathing pure oxygen since, under these conditions, all alveoli should contain nearly equal and constant O_2 tensions. The difference in pO_2 between alveolar and arterial samples in 5 subjects breathing 100% oxygen ranged from 4 to 15 mm Hg, indicating that a maximum of about 1% of the cardiac output has not been exposed to oxygen in the alveoli. The use of air, low oxygen and high oxygen inhalation may permit estimation of the relative importance of poorly ventilating alveoli and addition to pulmonary venous blood of blood which does not pass through alveolar capillaries.

The law relating blood flow to perfusion pressure HAROLD LAMPORT *Laby of Physiology, Yale Univ School of Medicine, New Haven, Conn*. Blood flow (I) in the hindlimb of a dog varies with the n th power of perfusion pressure (P). When vascular tone rises, n increases and the constant (C) in the formula, $I = CP^n$, shifts in a manner which needs to be correlated with the corresponding changes in vessel dimensions. This logarithmic pressure flow curve characterizes pseudoplastic fluids. When slippage in the fluid does not occur (a discontinuous change in its flow character), the law of flow in a capillary of length L and radius R for pseudoplastic fluids is $I = \frac{\pi R^3 m}{n+3} \left(\frac{RP}{2L} \right)^n$, where m and n are constants for the fluid in the tube. Perhaps blood, at high flow rates, should be considered to 'slip', the central streaming red cells with their longer dimension oriented axially being distinct from the surrounding plasma sheath. However, a gradual change in the flow character of the blood from vessel wall to axis seems more likely. Since the pressure-flow relation of blood is fairly well described by the same logarithmic expression which is effective for pseudoplastic fluids without slippage (oil-water emulsions analogous to blood are an example), the development for the glass capillary has been applied to the blood vascular system.

After allowing for the effects of branching of vessels, etc., an equation results which tested satisfactorily in a set of four pressure-flow curves on the same preparation under different degrees of vasoconstriction

Tetraethylammonium and gastric motility of the dog ARDELLE LANE (by invitation), C R ROBERTSON (by invitation), and M I GROSSMAN *Dept of Clinical Science, Univ of Illinois College of Medicine, Chicago, Ill* Gastric motility in the human is inhibited by tetraethylammonium (TEA). As the gastric secretory response to histamine is decreased by TEA in the human and not in the dog, this study was undertaken to determine if this species difference exists in regard to the effect of TEA on gastric motility. A series of x-ray studies on dogs given a barium meal was made with and without TEA (10 mg/kg I.V.). Films were taken immediately after the meal and in the case of TEA administration immediately after the drug was given and at half hour intervals for a period of 2 hours and at hourly intervals until the stomach was empty. A series of x-ray studies on dogs directly after a barium meal and simultaneous administration of atropine and epinephrine (1 mg of each) were taken as a control procedure for comparison with the effects of TEA. Gastric motility tracings before and after intravenous administration of TEA were made in gastric fistula dogs by the balloon water manometer method. In the x-ray studies gastric tone and emptying time were not appreciably changed by the administration of TEA. In the experiments in which atropine and epinephrine were given gastric tone fell as shown by x-ray. The kymographic records of gastric motility showed individual variation through motility was either unaltered or slightly inhibited for a few minutes. These studies indicate that in the dog gastric motility does not respond as in the human to the administration of TEA.

Electrocardiographic findings in anthracosilicosis LEONARD P. LANG (by invitation) and HURLEY L. MOTLEY *Dept of Medicine, Jefferson Medical College and Cardio-Respiratory Lab, Barton Memorial Division of Jefferson Hospital, Philadelphia, Penna* The incidence of right heart strain as manifest by electrocardiographic changes was correlated with physiological studies of pulmonary function, chest roentgenograms and fluoroscopic examination in over 150 patients with respiratory complaints and a history of prolonged exposure to dust inside coal mines (20-45 years). Post-mortem examinations of miners have revealed that there is a high incidence of right ventricular hypertrophy and that many eventually die in cardiac failure. The physiological studies used for comparison with the electrocardiographic findings included maximal breathing capacity, total lung

volume, the degree of emphysema as measured by expressing the volume of residual air as percentage of total lung volume, and the mean partial pressure of O_2 in arterial blood (Riley method). Cardiac fluoroscopy was of little value in the study of these miners because the dense fibrous tissue masses in the hilar areas obscured the cardiac borders. Fixed rotation of the heart and fibrous adhesions complicated the interpretation of an electrocardiographic diagnosis of right ventricle hypertrophy. No apparent correlation was noted between the x-ray stage of silicosis as classified from the roentgenogram and the electrocardiographic changes. However, a relationship was observed between the incidence of right heart strain and the degree of emphysema based on quantitative measurements of residual air. In general the lower the resting mean arterial pO_2 , the higher the incidence of right heart strain, however, short induced periods of acute hypoxia produced minimal electrocardiographic changes.

The effect of handometer exercise upon normal grip strength ELEANOR M. LARSEN (introduced by W. J. MEEK) *Dept of Physiology, Univ of Wisconsin Medical School, Madison, Wis* The usual grip strength of normal individuals is determined largely by their occupation. If normal grip strength may be increased by Handometer exercise, the hand strength of individuals weakened by injury or disease might be expected to improve by employing the same method. The purpose of this investigation was to determine the effect of Handometer exercise upon normal grip strength. The usual hand strength of 14 young adult women, right-handed with one exception, was measured by a grip dynamometer before and after 20 bouts of work performed bi-weekly. The exercise apparatus was the Handometer which consists essentially of a sphygmomanometer-type hand bulb attached to an adjustable air-pressure system gauge. The work of compressing the bulb against a constant resistance of 30 lb pressure was continued at the rate of 60 contractions per minute until the needle could no longer be held constant. The number of contractions were counted and recorded for each hand. The results for every subject consist of 3 grip dynamometer readings for each hand pre- and post-exercise, and 20 sets of Handometer data for each hand. The grip dynamometer data were analyzed statistically. The results indicate that the usual right hand grip strength is stronger than the left, and that the Handometer exercise increased the grip strength in both right and left hands, with a slightly greater increase in the strength of the left hand.

Renal mechanism of albumin excretion in patients with nephrotic syndrome HENRI D. LAUSON, FRANCIS P. CHIVARD (by invitation), and

HOWARD A. EDWIN (by invitation), *Hospital of The Rockefeller Inst. for Medical Research, New York City*. Intravenous administration of Red Cross human plasma albumin to nephrotic children 3 to 5 years old has made possible a study of the mechanism of albumin excretion. The amounts given varied from 18 to 37 gm. Albumin concentrations in plasma and urine were estimated by Chow's immunological method (*J. Biol. Chem.*, 104: 457, 1935). The plasma concentrations varied from 0.2 to 0.9 gm. per 100 ml. before infusion, increased by 1 to 2 gm. after infusion, and then fell during the next 24 to 48 hours, during which repeated clearances of albumin, and in some cases, insulin and endogenous creatinine were measured, together with plasma volume. The plasma volume varied in the same direction as the albumin concentration. In about half the experiments albumin clearance was approximately constant with all concentrations of plasma albumin. In the other experiments, however, during the first few hours after the albumin infusion, when plasma volume and albumin concentration were near the maximum, the albumin clearance rose 50 to 100%. Creatinine clearances did not show proportional increases, suggesting that the rise in albumin clearance was due to some cause other than those which control the glomerular filtration of water and electrolytes. The data are consistent with the interpretation that the cause of nephrotic albuminuria is increased glomerular permeability to albumin, almost all of the filtered albumin being excreted. The rise of albumin clearance is correlated with plasma volume expansion, and it may be that this expansion mediates a further increase in glomerular permeability.

The elasticity of the rat lung. RICHARD W. LAWTON AND ALLEN L. KING (introduced by JAMES D. HARDY). *Dept. of Pathology, Cornell Univ. Medical College, New York City, and Dept. of Physics, Dartmouth College, Hanover, N. H.* Changes are observed in elasticity of rat lungs with age. Retardation of growth by restriction of diet also alters the observed elastic characteristics of the lungs (Bixton, Harnen and Pierlup, *J. Gerontology* 4: 105, 1946). Chronic pneumonia and bronchiectasis are eventually found in a high percentage of rats of advanced age. A mathematical analysis of elastic properties of rat lungs was undertaken, utilizing the data of the above authors, in order to evaluate the relation of the elastic changes to aging and the disease process. A single alveolus is generalized as a hollow shell whose wall is composed of a mesh of rubber like molecules arranged as irregular closed rings. The whole lung is considered as a multiple of the single alveolus. The equation based on the current statistical mechanical theories of high polymers, $p - p_0 = A(c_0/r)^2 [1 + \beta(r/c_0) - (c_0/r)^2 (1 + \{\beta(c_0/r)\}^2)]$,

In the equation p and c_0 are the initial and p and r the distended pressure and radius respectively. The constant A is proportional to the number of elastic chains participating in the distension. The parameter β characterizes the elastic chains in the manner similar to Young's modulus. The notation $1/r^3$ is the inverse Langevin function. The changes in the constants of the equation are correlated with the growth curve and the incidence of disease in the rats.

Biological studies with 4-methylestrone. J. H. LAWSON and MARY LEO CLARY (by invitation). *Rutgers Univ., New Brunswick, N. J., and Ciba Pharmaceutical Products, Summit, N. J.* Introduction of a methyl group into the aromatic ring of estradiol is reported to abolish its activity. Tests involving the effect of methylating estrone are here presented. 4-methylestrone failed to stimulate uterine weight or histology in immature rats 18 hours after the single subcutaneous injection of as much as 2.0 mg. or after 10 daily injections of 0.25 mg. Furthermore, 1.0 mg. of 4-methylestrone did not alter the uterine stimulating action of concomitantly injected estradiol benzoate (2 μ g.) when both steroids acted over 18 hours. The estrogenic action of 0.01 mg. of estradiol benzoate injected for 10 days was not influenced by the simultaneous administration of 0.25 mg. of 4-methylestrone in immature female rats. A single injection of 1.0 mg. did not influence seminal vesicle weight of immature male rats in 72 hours nor did it interfere with the action of 0.25 mg. of testosterone propionate. Administration of 0.5 mg. of 4-methylestrone daily for 10 days to 22 day old male rats failed to influence body weight increase or to alter the weights of the pituitary, adrenal, thymus, kidney, testis, seminal vesicle or ventral prostate. The poundotrophic hormone content of the pituitary was normal. Thus the estrogenic action of estrone is greatly reduced or abolished by the introduction of a methyl group.

Plasma and liver protein concentrations in adrenalectomized and in thiouracil-fed adrenalectomized rats. J. H. LAWSON. *Bureau of Biological Research and Dept. of Zoology, Rutgers Univ., New Brunswick, N. J.* Adrenalectomized adult male rats maintained for 20 days on 1% NaCl and pair fed normals have comparable plasma protein levels although plasma albumin concentrations are subnormal, a reflection of subnormal food intake. Deoxycorticosterone acetate (Percorlon, Ciba) (DCA) at 0.5 mg. daily permitted normal food intake and growth in adrenalectomized rats. Pair fed controls exhibited normal plasma protein concentrations but the operated rats' plasma albumin level was not improved above that of a salt maintained rat due to either hemodilution or hormone deficiency. Hypothyroidism increases plasma pro-

bulin levels and thiouracil increases liver protein. Hypothyroidism in adrenalectomized rats maintained with NaCl or with DCA was studied by feeding 0.25% thiouracil for 20 days and comparing results with pair fed adrenalectomized and normal rats. Food intake was reduced by thiouracil with body weight loss resulting. Total plasma protein and plasma globulin levels increased following thiouracil. NPN was also higher whereas hematocrit decreased. Thyroid and liver weights were significantly above those of controls and analysis of the liver revealed a normal water content but a significant increase in total and relative amounts of liver protein in thiouracil fed rats. Adrenalectomized control rats maintained liver protein as well as pair fed normal rats. Thus, adrenalectomy does not alter the action of thiouracil on plasma and liver proteins.

Predisposition to vasodepressor properties of morphine induced by hemorrhagic hypotension. RICHARD E. LEE (by invitation) and BENJAMIN W. ZWEIFACH, *Dept. of Pharmacology, Syracuse Medical College, Syracuse, N. Y. and Dept. of Medicine, New York Hospital, New York City.* Several investigations concerning the action of morphine in hemorrhagic shock have not shown any consistent notable vasodepressor action. The agent was administered either prior to hemorrhage or during the early phases of a prolonged hypotension. Neither situation adequately duplicates the usual clinical sequence of events. In this study the morphine was administered following restoration of normal blood pressures by blood transfusion after a prolonged hemorrhagic hypotension, as well as prior to and during early 'shock.' Based on blood pressure recordings and direct visual observation of omental peripheral blood vessels, usual doses of morphine (1-3 mg/kg intravenously) in unhemorrhaged dogs produce no significant or persistent vasomotor disturbances. When given early in hemorrhagic shock (1-2 hr after initial bleeding) morphine administration is followed by a transient fall in blood pressure, accompanied by temporary vasodilatation with slowing of peripheral blood flow. In spite of restoring normal blood pressure by transfusion, after prolonged hemorrhagic shock, morphine in these doses is followed in all instances by a sharp severe fall in blood pressure. This coincides with observed arteriolar dilatation, depression of arteriolar reaction to topically applied epinephrine, and a severe slowing of peripheral blood flow, with stagnation occurring in the venular components of the capillary bed. Although immediate further transfusions were given each animal, 3 of the 12 dogs died in profound peripheral vascular collapse within 15 minutes after receiving morphine.

Physiological effects of bacterial polysaccharides upon the cardio-vascular and neuro-muscular systems. CHESTER E. LEESE and K. VIRGINIA GREENE (by invitation), *Dept. of Physiology, School of Medicine, George Washington Univ., Washington, D. C.* Rabbits were given doses of polysaccharide from 2 to 25 gamma/kg. Most of the animals showed a strong pyrogenic response associated with the usual maladjustments. Many animals lost the use of their body-righting reflexes. Lethal doses produced convulsive seizures, urination, defecation, and vomiting preceding death. Cats were less affected by the dosage level effective in rabbits. Pyrogenic reaction was noted before decerebration. Decerebration was often fatal when the animal was under the influence of the drug. If the drug was withheld until the animal recovered from decerebration, it tolerated a higher dosage without pyrogenic response. The cat showed lowering of arterial blood pressure, and an increased venous pressure. Both electrical and chemical stimulation of the vascular reflexes indicated a loss in the controlling power of the autonomic nervous system, or a lesser ability of smooth muscle to accept the stimuli. The vagus, splanchnic, and cardiosympathetic nerves required an increased strength of stimulus under polysaccharide influence. Assays with adrenalin, acetylcholine, pitressin, and histamine pointed to a loss in nervous response, rather than a decrease in the ability of smooth muscle to accept stimulation. Turtles perfused with polysaccharide showed cardiac changes. First to appear was an occasional dropped beat, followed by the various stages of heart block, and finally, complete dissociation. Tremendous dilation of both auricles and ventricles was noted. There occurs a progressive loss in the effectiveness of adrenalin or acetylcholine when added to the perfusate. Stimulation of the vagus also becomes less effective.

Food packages as a supplement to the German nutrition. G. LEHMANN (introduced by D. B. DILL), *Max Planck Inst fuer Arbeitsphysiologie, Dortmund, Germany.* The German nutrition of a man doing no heavy work reaches 1850 cal per day. This includes 47 gm of protein, of which only 11 gm are of animal origin, and about 20 gm of fat. A food parcel raising the nutrition of a family of 4 for one week to a normal level therefore, should contain foodstuffs rich in protein and fat, for instance the following: 2.5 lb of corned beef, 1 lb of whole milk powder, 1 lb of cheese, 0.5 lb of powdered egg, and 1 lb of margarine. Instead of corned beef, dried and smoked meat could be used. In contrast to the view of some nutritionists, the housewife will not take soy beans or other legumes as a valuable substitute for meat. The German housewife is not fond of pre-cooked meals, but

prefers basic foodstuffs. The German nutrition is very rich in carbohydrates. Therefore, foodstuffs that are predominately carbohydrate should be avoided. Chocolate and cocoa are very welcomed and useful. Coffee and tea are important because of their stimulating effect. The addition of fruit juices, marmalade, sweets, spices, etc. is less a matter of nutrition than a matter of making people happier. We are wrong in looking upon the question of food parcels from the point of view of the scientist only. Apart from raising the German nutrition to a normal level, they have the ideal task of intensifying friendship and understanding between men and nations.

Central hyperglycemic action of 1-(3,4-dihydroxyphenyl) 2-isopropylaminoethanol (isuprel)
A LEIMDORFER, *Dept of Pharmacology, Loyola Univ, Chicago, Ill.* In dogs, under nembutal, the effects of intravenous (i v) and intracisternal (i c) injection of isuprel on blood-sugar, blood pressure, and electrocardiogram were studied. Nembutal itself produced no changes in blood sugar. After i v isuprel, 75 micrograms/kg, only a small, short lasting increase in blood-sugar occurred (onset about 15 minutes after injection, highest increase 40 mg per 100 ml). The preinjection level was reached 45 to 60 minutes after injection. In contrast, after i c injection of the same amount, a much greater and long lasting increase in blood-sugar was found (onset about 15 minutes after the injection), the blood-sugar continued to rise for entire period of the observation (3½ hours), at that time it had risen to 180 mg per 100 ml.

After i v isuprel, a marked fall in blood pressure, a marked tachycardia and an extremely deep depression of the S-T segments were recorded. These changes were much smaller after i c isuprel. There seemed to be no direct relation between changes in blood-sugar and those in blood pressure and heart rate. Of importance might be the fact that after i c isuprel the blood-sugar was continuously rising whereas the changes in blood pressure and electrocardiogram were approaching the pre-injection levels. This fact and the particular blood-sugar curve after i c isuprel in contrast to that following i v isuprel suggest that the action of i c injection of isuprel in raising blood-sugar implies action on structures (centers) bathed by cerebrospinal fluid. These observations about isuprel which has an action like sympathin I are in conformity with our previous findings.

A method for collecting end-expiratory air from the oral cavity GERSON LESSER, MORTON GALTSTON, and MARVELIN PRUSS (introduced by J MURRAY STEELE) *Research Service, Third New York Univ Medical Division, Goldwater Memorial Hospital, New York City.* In elderly or diseased patients it has often been impossible to collect alveolar air samples by the Haldane-Priestley

method due to their inability to cooperate in performance of the necessary respiratory maneuvers. To overcome this difficulty and to maintain an undisturbed respiratory pattern, a simple, inexpensive method for collecting end-expiratory samples is being studied. Air samples are drawn at the end of a usual expiration through a narrow, semi-rigid tube, threaded through a rubber mouth-piece with its proximal open end 4-5 cm within the oral cavity. The other end of the tube is connected to a small 3-way stopcock which is attached to the end of an evacuated mercury gas sample bottle. The stopcock permits washing out the tube with expired air just prior to collection of the end-expiratory sample. Preliminary evaluation of 40 observations in 4 young, healthy subjects suggests that for each individual there is a consistent relationship between the composition of end-expiratory air and alveolar air (Haldane-Priestley, end-expiratory). The $p\text{CO}_2$ was always lower (individual means of $\Delta p\text{CO}_2$ were 1.6 to 4.1 mm Hg), and $p\text{O}_2$ was always higher (individual means of $\Delta p\text{O}_2$ were 2.4 to 7.9 mm Hg) in end-expiratory than in alveolar air. In any given subject the greatest variation of a single observation from his mean was 3.5 mm Hg $p\text{CO}_2$ and 6.4 mm Hg $p\text{O}_2$ for end-expiratory air (26 observations), and 1.1 mm Hg $p\text{CO}_2$ and 2.7 mm $p\text{O}_2$ for alveolar air (14 observations).

Analysis of the electrocardiographic pattern produced by injection of epinephrine and nor-epinephrine in cats EUGENE LEPECHKIN and W RAAB (introduced by F J SICHEL) *Division of Exptl Medicine, Univ of Vermont College of Medicine, Burlington, Vt.* Two to 6 seconds after intravenous injection of 20-40 micrograms epinephrine or nor-epinephrine in 4 cc Ringer, a transient elevation of the T-wave in unipolar precordial or direct leads from both ventricles is observed. This elevation lasts 2-7 seconds, appears on injection of corresponding amounts of plain Ringer, and is due to cooling of the subendocardial ventricular muscle layers. The subsequent changes are due to the epinephrine or nor-epinephrine proper. Ten to 15 seconds after injection T becomes depressed over the right ventricle and elevated anew over the left ventricle (Phase I). During Phase II (until the 40th-50th second), T is inverted over the right ventricle, flattened (sometimes inverted) over the left ventricle. Phase III extends until the 120th-160th second and is characterized by marked elevation of T over both ventricles. In some cats T may again become temporarily inverted over the left ventricle between the 300th-400th seconds (Phase IV). These changes of the T-wave are independent of the changes of the heart rate. They are not due to blood pressure elevation (increased heart work), as they appear even if this elevation is abolished or reversed through previous administration of certain sympatholytic drugs (933F, SY28, DHE180,

Priscol) Other sympatholytic drugs (DHE 45, SY30) inhibit both the hypertensive reaction and the electrocardiographic changes. The latter cannot be due to direct action of epinephrine on subendocardial muscle layers of the right ventricle, as they appear in similar sequence and magnitude on injection of epinephrine into the left auricle.

Lecithinase activity of epiphyseal cartilage of the foetal pig MILTON D. LEVINE and RICHARD H. FOLLIS, JR. (introduced by JOHN EAGER HOWARD) *Depts. of Medicine and Pathology, Johns Hopkins Univ., Baltimore, Md.* Lecithinase of the type described by Macfarlane and King (*Biochem J.* 35: 884, 1941) has been demonstrated in the epiphyseal cartilage of foetal pigs. Homogenates of such cartilage, when incubated with lecithin suspension substrates in the presence of Ca^{++} , results in the liberation of neutral fat and free choline while the phosphorus of the substrate goes from the fat soluble to the water soluble state. The mechanism is thought to be as follows: Lecithinase splits lecithin into phosphocholine and neutral fat. Phosphocholine is a substrate for phosphatase, hence we have a hitherto undescribed source of phosphate ion. Lecithin and the appearance of neutral fat in cartilage will be discussed.

Nature of the action of insulin on the level of serum inorganic phosphate R. LEVINE, S. D. LOUBE (by invitation) and H. F. WEISBERG (by invitation) *Dept. of Metabolic and Endocrine Research, Medical Research Inst., Michael Reese Hospital, Chicago, Ill.* It is well known that the administration of insulin, glucose or adrenaline causes a fall in the level of inorganic phosphate of the serum. We have previously shown (*Am J Physiol* 134: 40, 1941) that no decrease in serum phosphate occurs after the administration of glucose or adrenaline to depancreatized dogs, indicating that the phosphate lowering effect of these substances is mediated by insulin. It was then concluded that the fall in serum phosphate is one of the direct actions of insulin. The rate of entry of fructose into tissues, as measured by the rate of disposal of intravenous fructose, is not diminished by the complete absence of insulin (pancreatectomy) (*Federation Proc.* 6: 21, 1947). We have, therefore, determined the effect of intravenous fructose on the serum phosphate level of untreated depancreatized dogs. In 9 of 10 animals there was a significant drop in inorganic phosphate of the serum following fructose administration. Under similar circumstances intravenous glucose does not affect the phosphate level. It is, therefore, concluded that the fall in serum phosphate is an expression of the rate at which a hexose enters the tissues. Insulin enhances this rate for glucose. Fructose, which enters tissues at a rapid rate even in the complete absence of insulin, causes a phosphate fall independent of the hormone. We can therefore no

longer consider the fall in serum phosphate as a direct action of insulin. The only presently proven primary action of insulin is the increase in the rate of entry of glucose into tissue, specifically skeletal muscle.

Three dimensional electrocardiography RAPHAEL B. LEVINE (by invitation) and OTTO H. SCHMITT *Depts. of Zoology and Physics, Univ. of Minnesota, Minneapolis, Minn.* Much of the difficulty in the interpretation of electrocardiograms lies in correlating records of the several different potential variations which occur simultaneously. If it were possible to combine all of the information contained in the numerous individual lead electrocardiograms into a single interpretable pattern, compactness would be obtained with no loss in generality. The 'vector cardiogram' of Wilson and Johnston is an approach in two dimensions to this ideal. Development of the 3-dimensional cathode ray oscilloscope has made possible the extension of electrocardiographic presentation to three dimensions. This instrument is capable of utilizing three electrical signals in such a way as to form a picture which to the eyes is a stereoscopically correct perspective pattern in space. An application of such an oscilloscope which immediately suggests itself is the presentation of a true 3-dimensional vector electro-cardiogram. This requires development of orthogonal leads or their electrical equivalent. In practice, it may prove entirely satisfactory to present data from conventional non-orthogonal leads in orthogonal form. As a further improvement, a computer currently under development will permit rotation and translation at will of any three-dimensional display to the angle and range most advantageous for viewing. These 3-dimensional displays can readily be photographed on standard film for stereoscopic viewing, and lend themselves well to the preparation of wire models.

Fat metabolism in Alaskan Eskimos VICTOR E. LEVINE and CHARLES G. WILBER *Arctic Research Lab., Office of Naval Research, Point Barrow, Alaska.* The blood sera of Point Barrow Eskimos (adults and children of both sexes) were taken for estimation of various lipid components. To date 50 analyses have been completed. Mean values are as follows:

LIPID COMPONENT	ALASKAN ESKIMOS	CANADIAN ESKIMOS (CORCORAN & RADINOWITCH)
	mg/100 cc	mg/100 cc
Total fatty acids	701.3	535
Total cholesterol	221.6	141
Free cholesterol	124.9	46
Ester cholesterol	96.7	95
Lipid phosphorus	14.2	—
Phospholipids	355.0	164

The following were calculated cholesterol/lipid phosphorus, 21.4, free cholesterol/total cholesterol, 0.56, cholesterol/fatty acid, 0.31. Our results compared with normal values for whites are high. The blood was taken late in August and early in September 1948, during which time walrus and seal were plentiful. The Eskimos were living close to their native diet. The values may, therefore, reflect a pronounced 'alimentary fat tide' due to the ingestion of fat rich meals. Our findings are not in accord with those of Corcoran and Rabinowitch (*Biochem J* 31:343, 1937) who found low lipid values in the bloods of 27 Canadian Eskimos taken at random. They did, however, report higher lipid values for natives on a meat diet compared to those for natives on a mixed diet. Under field conditions in the Arctic it is extremely difficult to collect blood in true fasting condition. Our results reflect a high fat intake, while those of the Canadian investigators may reflect a low fat intake or even a diet close to a starvation level.

Measurement of the intracellular cation in the dog. MARVIN F. LEVITT and MARIO GAUDINO (introduced by HOMER W. SMITH) *Dept of Physiology, New York Univ College of Medicine, New York City*. The measurement of the intracellular concentration of any cation in the living animal requires the determination of the volume of intracellular fluid and of the total intracellular cation. In our present experiments the intracellular fluid was calculated as the difference between total body water (D_2O space) and extracellular fluid (inulin space, *Proc Soc Exptl Biol & Med* 68:507, 1948). The total amount of body cation (Na or K) was measured by *in vivo* dilution of Na^{24} and K^{42} . A known amount of isotope was injected intravenously and the ratio of isotope to total cation in the plasma was followed until equilibrium was attained. Equilibrium requires 3 hours for Na^{24} (Kaltreider et al *J Exptl Med* 74:569, 1941), and, according to our present observations, 9 hours for K^{42} in the dog. Observations with carefully purified K^{42} indicate that this cation penetrates tissues so rapidly that 85% of equilibrium is reached within 3 hours. At equilibrium, the counts retained in the body (considering urinary loss) divided by the total counts per mEq of Na or K in the plasma, gives the total Na or K in the animal. In 2 dogs the average values were

Inhibition of a proteolytic enzyme system of blood. JESSICA H. LEWIS (by invitation) and JOHN H. FERGUSON *Dept of Physiology, Univ of North Carolina, Chapel Hill, N C*. In certain human pathological conditions such as shock, anoxia, and severe liver disease, the phenomenon of liquefaction of a formed blood clot (fibrinolysis) has occasionally been observed. Normal serum contains no active lysin, the enzyme causing fibrinolysis, but does contain large amounts of the inactive precursor, prolysin, and a potent inhibitor, antilysin. The present report, dealing with certain reactions of antilysin, is part of a series of studies by which we are endeavoring to shed some light upon the mechanism of fibrinolysis in various human disorders and hemorrhagic shock in dogs. Standard curves are presented for the determination of potency of lysins partially purified from dog, human, and bovine sera, as measured by the lysis of a standard fibrin clot. The three curves are apparently identical. There is no detectable species specificity of each antilysin for its homologous lysin, as tested by the antilysin assay method here presented. Serum antilysins do differ in important particulars from certain purified proteolytic enzyme inhibitors isolated from soybean, navy bean, and pancreas. Contrary to the suggestion that proteolytic enzymes may be inhibited by the products of protein digestion, it is shown that serum lysin is not inhibited by the products of fibrinolysis. Attempts were made to study the nature of the enzyme-inhibitor complex. It could not be split by differential heat destruction of the enzyme nor by chloroform treatment which has long been known to remove inhibitor from such prolysin-antilysin mixtures as serum.

Studies on lipoprotein in dog serum. LENA A. LEWIS and IRVINE H. PAGE *Research Division and the Bunts Inst of the Cleveland Clinic Foundation, Cleveland, Ohio*. Four protein peaks can be demonstrated by ultracentrifugation of dog serum previously diluted and dialyzed against 1.0, 1.5 or 2.0 M $NaCl$. They are similar to those described by Pedersen for human serum. The peak with the slowest sedimentation rate is not demonstrated at salt concentrations of 0.6 M $NaCl$ or less, and is only poorly resolved with 0.75 M $NaCl$. Using 2.0 M $NaCl$ —2% dog serum protein solution, prolonged centrifugation in the preparative rotor was done. The top layer which had a 'milky appearance' was removed and studied by electrophoresis and ultracentrifugation. With phosphate buffer pH 7.8, ionic strength 0.16 M, two fractions were demonstrated by electrophoresis. One had a mobility similar to that of serum albumin (dog) and represented 57% of the total area. The slower moving component had a mobility similar to that of α_2 globulin (dog) and represented 43%. The albumin in the dog

serum was 47.9% and the α_2 globulin 6.2% of its total protein. The slow sedimenting lipoprotein of human serum has the electrophoretic mobility of β_1 -globulin. In the ultracentrifuge two peaks were demonstrated in the lipoprotein concentrate when salt concentrations of 1.0 and 1.5 M NaCl were used. The faster sedimenting component had a sedimentation rate similar to serum albumin and represented 62% of the total area. The slower sedimenting fraction represented 38%. A slow sedimenting lipoprotein with the electrophoretic mobility of α_2 -globulin can be demonstrated and concentrated from dog serum by ultracentrifugation when salt concentrations between 1.0 and 2.0 M NaCl are used.

Metabolism of lactate by the isolated dog gastrocnemius studied with α, β - and carboxyl-labeled lactate. NATHAN LIFSON, AKIRA OMACHI (by invitation), and SHIRLEY L. MICHEL (by invitation) *Dept. of Physiology, Univ. of Minnesota, Minneapolis, Minn.* The isolated gastrocnemius of a nembutalized dog was perfused at physiological pressures and temperatures by means of a closed, pump-oxygenator circuit, the animal's own heparinized blood serving as the perfusion fluid. The muscle was either at rest or was stimulated via the sciatic nerve with maximal single shocks at a frequency of 2/sec for 2-3 hours. Either α, β - or carboxyl-labeled racemic C^{13} -sodium lactate was administered to increase the blood level by approximately 1.4 mM/100 cc. In 3 experiments with stimulated muscle it could be calculated from

$$\frac{\text{total mM } CO_2}{3} \times \frac{\text{atom \% } C^{13} \text{ excess in respiratory } CO_2}{\text{atom \% } C^{13} \text{ excess in administered lactate}}$$

that 0.56-0.94 mM/100 gm of muscle/hr of administered lactate was converted to respiratory CO_2 . The addition of non-isotopic acetate or succinate to give blood levels of about 0.8 mM/100 cc reduced these values by at least 50%. In these latter experiments acetate, succinate, and lactate were recovered from blood and/or muscle and analyzed for C^{13} . Resting muscles, to which was administered glucose with or without insulin, also converted administered lactate to respiratory CO_2 but at slower rates than did stimulated muscles. In the stimulation experiments the glycogen content of the perfused muscle decreased in comparison with that of the corresponding unperfused muscle of the other side. In the experiments with resting muscles, the glycogen content increased when insulin was administered. However, in no instance was definite significant excess C^{13} found in the muscle glycogen. From the above data it is

concluded that 1) lactate is converted to CO_2 by both resting and active mammalian skeletal muscle, 2) the presence of other substrates (acetate and succinate) decreases the rate of conversion of administered lactate to CO_2 , and 3) unequivocal evidence for the conversion of lactate to glycogen in either contracting or resting muscle was not obtained.

Further studies on the single muscle fiber membrane potential. G. LING and R. W. GERARD *Dept. of Physiology, Univ. of Chicago, Chicago, Ill.* Studies on the membrane potential of frog sartorius fibers, singly impaled with a capillary electrode (Ling, Ling and Gerard), have been extended. The A potential fraction, between 54 and 78 mV, has been shown to parallel fairly well the actual CrP content under the influence of tetanization, methylene blue, cyanide, azide, hydroxylamine, iodoacetate alone or with lactate. The B potential, between 0 and 54 mV, is not directly dependent on metabolism but varies with K^+ , increased K^+ lowers the plateau between A and B potentials which appears when the A potential has been abolished by some of the above conditions. Continuous irrigation of the muscle surface is necessary to avoid accumulation of leaking K^+ . Thus, in unstirred K -free solutions, the potential rises irregularly, seldom above 90 mV, in flowing ones, it can rise to 108 mV. Also, the fall in N_2 is less in flowing than still solutions, and that in IIA starts later. In general, potential varies inversely as log of external K^+ concentration (slope = 44 mV per tenfold change) to -7.0 mV at 4 times isotonic K^+ . The slope of the K^+ -potential curve is seemingly altered by addition of Ba^{++} but not by Ca^{++} . Exposure to CO_2 , in contrast to nerve, lowers the normal value by 5 to 10 mV during 1 to 2 hours, return in air is complete in 1 hour. In 20% or 100% CO_2 , alike, the A potential is lost in half to one hour, returns in a few minutes. Absence of K^+ from the irrigation fluid does not alter the size of the CO_2 depression. Conclusions can be drawn from these data as to the nature of the membrane.

Effect of temperature on the membrane potential of the frog sartorius muscle. G. LING and J. W. WOODBURY (introduced by R. W. GERARD) *Dept. of Physiology, Univ. of Chicago, Chicago, Ill., and Dept. of Physiology, Univ. of Utah, Salt Lake City, Utah.* Variations of membrane potential with temperature were measured in the sartorius muscle of *Rana pipiens* by inserting a micro electrode directly into a single fiber. Four to eight potential measurements were made on each muscle at from 4 to 6 different temperatures between 3° and 41°C on a total of 28 muscles. The muscles were allowed to equilibrate at each temperature for at least 20

minutes Temperature was progressively increased in 14 experiments, decreased in ten, and first increased then decreased in four The averaged data from 8 muscles (temperature increasing) are tabulated below

T° C	5	15	20	23	30	37	39	40	40.5	41
V mv	71	80	83	85	87	85	83	80	71	63

For progressively increasing temperature from 5°C to 25°C the relation between log voltage and reciprocal of absolute temperature was approximately linear with a Q_{10} of 1.1 (activation energy 1700 calories) The mean Q_{10} for all muscles was 1.08 (1400 calories) Membrane potential reached a peak at approximately 30°C and fell precipitously and irreversibly above 35°C, in association with contracture The low temperature co-efficient may possibly represent the difference between energies of activation for penetration of the membrane by positive and negative ions produced by metabolic processes

A modified procedure for inulin determination in plasma and urine J MAXWELL LITTLE, JUNE HARRIS (by invitation) and LEWIS FRANKLIN (by invitation) *Dept of Physiology and Pharmacology, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N C* Oxidative destruction of glucose by heating in the presence of NaOH has been utilized to replace the usual destruction by yeasting (Selkurt *Methods in Medical Research* 1 197, The Year Book Publishers, Inc., Chicago, 1948) The effects of NaOH concentration and duration of heating in boiling water upon glucose and inulin were studied Incomplete glucose destruction (with 50-300 mg % solutions) or production of an absorbing intermediate compound was indicated by light transmissions of 93-99% when compared with a water blank set on 100% This residual absorption was almost completely rectified by the addition of 1.0 cc of 100 mg % glucose to the blank, which was set on 100% *Procedure* plasma, or diluted urine, containing 5-30 mg % inulin, is precipitated with CdSO_4 and NaOH after the addition of 1.0 cc of 100 mg % glucose solution Shake the mixture vigorously for 10 minutes, centrifuge, and filter through washed cotton To 4.0 cc of filtrate, in a large test tube, add 1.0 cc of 4.0 N NaOH, cover with marbles and immerse in boiling water for 10 minutes Cool, add 10 cc of diphenylamine reagent and immerse in boiling water for 30 minutes Cool the tubes and read in an Evelyn colorimeter using filter 620 Blank tubes contain plasma or urine without inulin Mean recoveries

and standard deviations with theoretical concentrations of 5, 10, 15, 20, and 30 mg % inulin for plasma were respectively 5.10 ± 0.293 , 9.93 ± 0.357 , 15.21 ± 0.664 , 20.25 ± 0.846 , and 30.53 ± 0.700 , for urine 4.98 ± 0.235 , 9.78 ± 0.272 , 14.94 ± 0.224 , 20.16 ± 0.479 , and 30.49 ± 0.523

Atrial hemodynamics in the presence of experimentally produced interatrial septal defects R C LITTLE (by invitation), J G HAWLEY (by invitation) and D F OPDYKE *Dept of Physiology, Western Reserve Univ Medical School, Cleveland, Ohio* Interatrial septal defects were produced in open chest dogs Right and left atrial pressures were recorded simultaneously The results of experimental alteration of atrial pressures before and after producing the defect are compared The left-to-right pressure difference between the atria which was observed previously in similar preparations without septal defects persists after producing the defect, although the differential appears to be decreased Rapid saline infusion elevates both left and right atrial pressures in the presence of an interatrial defect, but does not appear to increase left pressure as effectively as in the control However, right pressure does not exceed left, although the two pressures tend to equalize after a considerable volume of infusion

As in the control series, positive pressure inflation of the lungs (open-chest) results in an elevation of both right and left atrial pressure, but right increases more than left with a subsequent reduction of the pressure differential Persistence of a pressure differential is probably due to a difference between the volume-elasticity characteristics of the atria At equilibrium the volume flow into each atrium is equal Since the left atrium has the greater volume-elasticity coefficient, the pressure will be greater than that in the right atrium Experiments with a physical model indicate that this is a major factor in maintaining the pressure difference

Effects of breathing CO_2 on blood pressure and renal circulation in normotensive and hypertensive subjects W J LITTLE, J W AVERA and S W HOOBLER (introduced by M H SEEVERS) *Dept of Medicine, Univ of Michigan Hospital, Ann Arbor, Mich* The mean blood pressure increased 21% in 6 normotensive subjects and 16% in 5 hypertensive subjects during inhalation of a gas mixture containing 10% CO_2 and 90% O_2 This rise was theoretically due to increased vasomotor tone, but was probably in part the result of an increase in cardiac output, since it occurred after caudal anesthesia had been established to dorsal 3 The procedure was also associated usually with

renal vasoconstriction, while control studies utilizing hyperventilation of room air and rebreathing 100% oxygen had little effect on renal circulation. The following table summarizes observations with 6 normals and 5 hypertensives, showing the average (and range) percentage change during CO₂ inhalation.

	NORMOTENSIVES	HYPERTENSIVES
RPF	-13% (0 to -39%)	-23% (-9 to -66%)
RR	+46% (+7 to +110%)	+75% (+23 to +228%)
GFR	-2% (-31 to +16%)	-12% (-59 to +12%)
FF	+10% (0 to +17%)	+17% (+9 to +25%)

RPF is renal plasma flow (PAH), RR is renal resistance (Mean BP/RPF), GFR is glomerular filtration rate (mannitol), and FF is filtration fraction (GFR/RPF). The changes were usually abrupt in onset and offset, occurring only during the 10 min period of CO₂ breathing. The failure of a 'rebound' phenomenon to occur in the ensuing urine collection periods excluded the possibility that the changes were due to retention of urine in the renal pelvis. The evidence seems to indicate that the renal vasoconstriction observed in the human subject, during inhalation of 10% CO₂, is primarily the result of an increase in neurogenic vasoconstrictor activity.

Post-tetanic potentiation of presynaptic actions in the spinal cord. DAVID P. C. LLOYD *Labys of The Rockefeller Inst for Medical Research, New York City*. Monosynaptic reflexes of a given muscle are greatly increased for several minutes following brief tetanization of the nerve afferent for that muscle, the phenomenon resembling that studied in ganglia by Larrabee and Bronk, in frog by Bremer and Kleyntjens. Tetanizing afferent pathways, from other muscles or skin, that converge, directly or after internuncial relay, with the monosynaptic pathway of the given muscle may influence transmission therein for 15 seconds, but prolonged potentiation is not realized. Furthermore, penetration into motoneuron somata of antidromic volleys, depressed for several seconds following presynaptic tetani, is not further influenced. If, however, the nerves of two muscles, synergists or antagonists within a myotatic unit, are stimulated by single shocks so related in time that the volley in one nerve, through monosynaptic connection, facilitates or inhibits the monosynaptic reflex elicited by stimulation of the other nerve, then, following tetanization of the first-mentioned nerve, its conditioning action, facilitatory or inhibitory, upon the test reflex, is enhanced for

several minutes, the test reflex in isolation remaining unaffected. Now, since any activity evoked by means other than stimulation of the tetanized afferent fibers is not potentiated, and since the known synaptic actions of those afferent fibers all are, it follows that the process underlying post-tetanic potentiation must be sought in the rhythmically stimulated afferent fibers themselves. Recordings from the intramedullary afferent fibers of post-tetanicly increased impulses displaying subnormal velocity suggest that hyperpolarization (positive after-potential) by increasing in size the presynaptic impulses causes them to be more effective synaptic agents.

Effect of sham-feeding on gastric motor activity of the dog. STANLEY H. LORBER (by invitation), S. A. KOMAROV and HARRY SHAY *Samuel S. Fels Research Inst., Temple Univ. School of Medicine, Philadelphia, Penna.* The effect of sham-feeding on the gastric motor activity of a dog with an esophagotomy and gastrostomy has been studied by a balloon-kymograph technique. A balloon was introduced into the gastric antrum through the gastrostomy opening and, after a 30-60 minute period of observation, the dog was sham fed. Results observed were of two types and depended upon the basal motor activity. In the active stomach, sham-feeding abolished peristaltic waves and diminished or abolished tonus waves. The diastole of tonus activity was not altered appreciably. The above effects occurred promptly at the start of sham-feeding and preceded acid secretion by 5-7 minutes. The motor inhibition lasted for several hours. In the inactive stomach, sham-feeding resulted in the initiation of motor activity and in an increase in tonus. The waves induced were predominately of the tonus type but for a few minutes after sham-feeding peristaltic waves also occurred. The effects preceded or immediately followed the termination of sham-feeding. The results indicate that sham-feeding can induce or inhibit gastric motility depending upon the state of basal gastric activity.

Conversion of propionate carbon to liver glycogen in the intact rat, studied with C¹⁴, C¹³-labeled propionate. VICTOR LORBER, MARGARET COOK (by invitation) and JULIEN BORDEAUX (by invitation) *Dept. of Biochemistry, Western Reserve Univ. School of Medicine, Cleveland, Ohio*. Solutions of C¹⁴H₃C¹³H₂COO-Na and glucose were given to fasted rats by stomach tube. Resulting liver glycogen was isolated, hydrolyzed to glucose and the position of C¹⁴ and C¹³ in the glucose molecule determined (*J. Biol. Chem.* 159:475, 1945). Prior experiments (*Federation Proc.* 6:272, 1947),

Lorber, Lifson, Sakami, and Wood, unpublished) in which $\text{CH}_3\text{C}^{13}\text{H}_2\text{COO-Na}$ and $\text{C}^{13}\text{H}_5\text{CH}_2\text{COO-Na}$ were fed to different animals have indicated that isotope administered separately in the α and β carbons appears in both cases mainly in the 1,6 and 2,5 carbons of glucose from liver glycogen, and is equally distributed between these positions. In the present experiments in which it was possible to study the fate of isotope from both the α and β carbons of propionate simultaneously in the same animal, the above result has been confirmed. Following feeding of $\text{CH}_3\text{C}^{13}\text{HOHCOO-Na}$, the isotope is incompletely randomized between carbons 1,6 and 2,5 of the glucose from liver glycogen (Lorber, Lifson, Wood, and Sakami, *Proc Am Physiol Soc*, in press), positions 2,5 predominating. The results with propionate may therefore be interpreted to mean that for the conversion of propionate to pyruvate some pathway other than a direct conversion via α oxidation must exist.

Role of insulin in the metabolism of amino acids

WILLIAM D. LOTSPEICH, *Syracuse Univ College of Medicine, Syracuse, N Y*. It has been repeatedly demonstrated that the injection of insulin results in a fall in the plasma amino acid nitrogen. The best evidence to date indicates that amino acids are being synthesized into protein under the influence of insulin. In order to further clarify this problem the following study was undertaken. Normal adult female dogs, fasted for 12 hours, were injected intravenously with insulin (Hletin-Lilly) in doses of 2 U/kg body weight. The whole blood levels of the natural forms of the 10 essential amino acids were followed for 1 hour thereafter. All amino acids were determined on tungstic acid filtrates of whole blood by microbiological assay techniques using *Streptococcus fecalis-R*, *Leuconostoc mesenteroides* and *Lactobacillus arabinosus* as the test organisms. It was found that the blood levels of all amino acids fell at different rates. Arranged in the order of decreasing extent of fall the amino acids were leucine, lysine, isoleucine, valine, threonine, arginine, phenylalanine, histidine, methionine and tryptophan. It was further found that there existed a direct correlation between the quantity of each amino acid leaving the blood after insulin and the concentration of that same amino acid in dog skeletal muscle protein. This was taken as presumptive evidence that insulin plays a role in the synthesis of protein from circulating free amino acids.

Action of epinephrine on the pyloric sphincter as recorded by the pyloric inductograph. HORTENSE LOUCKES (by invitation), DANIEL A. BRODY (by invitation) and J. P. QUIGLEY, *Division of Physiology, Univ of Tennessee, Memphis, Tenn*. We have employed a modified form of the pyloric inducto-

graph of Brody and Quigley (*J Lab & Clin Med* 29:3 1944). By increasing the primary coil input from 60 to 1500 cycles per minute the 50 ohms resistance coils become more sensitive and much smaller coils have adequate sensitivity. The amplifier output has been rectified so that coil or sphincter movements are recorded as a line instead of a band. This facilitates interpretation of the records. Normal dogs, thoroughly trained to participate in the studies, were provided with two coils of 50 ohms resistance sutured at the pyloric sphincter diametrically opposite each other. The pyloric sphincter of the dog usually exhibited spontaneous rhythmic contractions having a 10-14 second cycle. This interval was not altered by the fasting or postprandial state but the contractions became more regular, of greater amplitude and spontaneous periods of inactivity were rare when the stomach contained food. The intravenous injection of epinephrine (0.5-4 gamma/kg) completely abolished postprandial motility for 30 to 85 seconds respectively and depressed motility for an additional 10 to 60 seconds respectively. During the recovery period the frequency of sphincter contractions returned to the pre-injection rate. Epinephrine increased the sphincter tone and this increase was of longer duration (30 to 240 seconds) than the motor inhibition. The latent period of epinephrine effect ranged from 15 to 25 seconds. A reduction in pulse rate paralleled the decreased sphincter motility. Doses less than 0.5 gamma/kg epinephrine appeared to be subthreshold for they produced questionable inhibition of sphincter motility, no effect on tonus and a slight decrease in pulse rate.

Absorption of sulfamylon. E. W. MCCLESNEY, M. E. AUERBACH (by invitation) and H. W. ECKERT (by invitation), *Sterling-Winthrop Research Inst, Rensselaer, N Y*. Studies on the absorption of Sulfamylon (homosulfanilamide, marfanil) have been retarded by the lack of a satisfactory method for its determination in blood. The method of Heideman and Rutledge (*J Pharmacol & Exptl Therap* 93:451, 1948) is open to several criticisms, principally on the ground that the metabolic product, p-carboxybenzenesulfonamide, also absorbs light in the region 265-270 m μ , and absorbs it more strongly than Sulfamylon. An alternate method for the determination will be presented, based on the Ehrlich and Herter reaction for α -amino groups (*Z physiol Chem* 41:329, 1904). The method involves precipitation of the whole blood proteins with trichloroacetic acid, adjustment of the filtrate to pH 9, and reaction with β -naphthoquinone sulfonate. The yellow derivative is extracted with methyl n-amyl ketone, and is de-

terminated in the photoelectric colorimeter using a 420 m μ filter. This method has been applied in studies of absorption of the drug. Dogs given 625 mg/kg by intravenous infusion showed blood levels ranging from 15 to 80 mg %, 30 minutes after the end of the infusion, the blood was essentially cleared of Sulfamylon in 5 hours. When the same dose was given orally, the peak blood levels ranged from 7 to 35 mg %, 2 to 3 hours after medication. In human subjects an oral dose of about 110 mg/kg gave peak blood levels of the order of 7 mg %, 1 to 2 hours after medication.

Inhibition of the knee jerk from tendon spindles of crureus G P MCCOUCH, I D DEERING (by invitation), W B STEWART and W W CHAMBERS (by invitation) *Depts of Physiology and Anatomy, Univ of Pennsylvania, Philadelphia, Penna.* In decerebrate cats, the muscles of the lower extremity were silenced by denervation or tenotomy except for quadriceps and usually semitendinosus. The limb was fixed by drills and a pelvic clamp. Muscle tension was recorded isometrically and action potentials, from a bare needle through rectus and crureus. The knee jerk was elicited by a mechanical tapper, which stretched the muscle by raising the lever shank. Conditioning volleys, usually below and never significantly above threshold for direct or neuromyal response, were delivered through bare needles of which one passed through the patellar ligament, the other transversely through vastocruureus a few millimeters proximal to the tendon of crureus. Inhibition curves may be preceded by facilitation at intervals between conditioning and test stimuli up to 2 msec. This is followed by a descending limb, relatively constant in shape and duration, which reaches maximal depth within 8 or 9 msec. Total duration of inhibition is variable, being greater with more proximal electrode positions, which involve more receptors, than with distal positions, which engage fewer end organs. It ranges from 20 to 100 msec. Two factors may be postulated to account for the shape of the curve. The first is facilitation from the inevitable involvement of muscle spindles by the conditioning stimulus. The second results from the multisynaptic character of the inhibitory arc and its consequent afterdischarge.

Vascular changes in the warmed ear during oximetry W J MCCRACKEN (introduced by J K W FERGUSON) *Dept of Pharmacology, Univ of Toronto, Toronto, Canada.* A photoelectric oximeter developed by Dr W Paul employs amplification and meters such that fluctuations of blood content of the ear ('ear thickness') are observable with each pulse beat and amount to 0.25-1.5 ma. The reading with the ear compressed and bloodless

is less than one ma, while fully warmed ears give readings of 9-15 ma, or about 8 ma more than unwarmed ears. Over and above fluctuations with the pulse, changes have been observed after a) compression of the ear (tissue anoxia for 3-5 min), b) hyperventilation, c) anoxia by holding the breath, and d) breathing oxygen. After compression of the ear the current increased by 0-3 ma in 19 subjects (av 1 ma) above the precompression reading, and returned to the precompression reading in 3-5 minutes. This is interpreted as reactive hyperemia which temporarily increased the blood content of the ear by an average of about 20%. Hyperventilation in 2 subjects produced vascular constriction, as shown by a decreased current of about 1 ma. Subsequent anoxia by breath-holding without increased intrathoracic pressure caused an increased current of about 4 ma above normal, indicating additional vasodilatation in the ear. Breathing O₂ (50, 75, and 99%) caused a decrease of current of 0-2 ma in 19 subjects (av 0.75 ma). The magnitude of this vasoconstriction did not seem to vary with O₂ % from 50-99%.

Experimental studies with psoriatic blood DAVID I MACHT *Dept of Pharmacology, Labys of Sinai Hospital, Baltimore, Md.* For 25 years, the author has been employing plant-physiological methods for studying pharmacological properties of blood. In this way by testing 1% solutions of sera in plant physiological saline on root growth of *Lupinus albus* seedlings, the presence of toxic substances was demonstrated in menstrual blood and in the blood of pernicious anemia, pemphigus, leprosy, and trachoma. Numerous experiments with psoriasis blood however on normal seedlings gave readings exactly the same as with normal blood sera. Three years ago, the author began experiments on the action of drugs and sera on seedlings which had been previously vernalized. He found that ethyl-carbamate was much more toxic for vernalized seedlings than for normal ones. Similarly it was discovered that psoriatic serum was toxic for vernalized seedlings but not for normal seedlings, all the other phytotoxic sera mentioned above did not show such a difference.

Vernalization (or 'yarovization') in these experiments was produced by chilling seedlings at 42°F in the dark (Miller, S C *Plant Physiology*, 1938). This finding in psoriasis is useful for diagnosis and also for the evaluation of therapeutic procedures. Thus exposure of psoriatic sera to x-rays *in vitro*, or to ultra-violet rays in quartz produce detoxification of psoriatic blood. These physical agents are employed with some success in the treatment of this disease. Extracts of *Smilax sarsaparilla* also detoxify psoriatic serum *in vitro*, and that drug has

also been employed clinically (*New England J Med* 227 128, 1942)

Physiological, pharmacological and biochemical studies on blood of animals in rage DAVID I MACHT and THOMAS HOFFMASTER (by invitation) *Dept of Pharmacology, Labys of Sinai Hospital, Baltimore, Md* Six different experimental studies were made on the blood of rabbits and cats before and after enraging them 1) clotting time of whole blood measured by the Lee White method, 2) prothrombin time estimated by Quick's method, 3) blood sugar determined by microchemical methods, 4) phytotoxic effects on root-growth of seedlings measured on *Lupinus albus* by Macht's method, 5) reducing power of blood sera for methylene blue studied in a substratum of crushed vegetable cells by Thunberg's method, 6) similar studies with serum on brain and muscle tissues, made by Thunberg's method

Coagulation time of whole blood in rage is markedly reduced, as much as 50% or more Prothrombin time is but slightly affected, the fluctuations being of little significance Blood sugar is markedly increased for 6 hours or more Phytotoxic properties of sera after rage are very striking and are exhibited by them even after refrigerating the blood specimens for 3 days Control experiments with intravenous injections of epinephrine also shorten coagulation time and produce hyperglycemia, but render the blood phytotoxic only when tested a few hours after drawing it, the phytotoxicity disappears, probably through oxidation, on standing several hours Significant differences also are shown between the reducing power of the sera after rage and after injections of epinephrine, respectively The results indicate that the blood changes in rage cannot be attributed entirely to adrenal effects, but involve other metabolic or endocrine disturbances

A new chemical method for the determination of histamine in biological materials FLOYD C MCINTIRE, MURIEL SPROULL, and FRANCES B WHITE (introduced by R K RICHARDS) *Dept of Biochemistry, Abbott Research Labys, North Chicago, Ill* The reaction between histamine and 2,4-dinitrofluorobenzene may now be used for the determination of histamine in biological materials The histamine to be determined is purified by the cotton acid succinate method (McIntire, Roth, and Shaw, *J Biol Chem* 170 537, 1947) The cotton acid succinate eluate is not neutralized, but is evaporated to dryness The dry residue is dissolved in a small amount of an alkaline buffer, an alcoholic solution of dinitrofluorobenzene is added and after 20 minutes at room temperature the solution is acidified Under the conditions employed, histamine reacts with dinitrofluorobenzene to yield

β -(4-imidazolyl-N-(2,4-dinitrophenyl)ethylamine This histamine derivative is separated from the excess reagent and from a number of dinitrophenyl-amino compounds by a micro counter-current extraction procedure Interference from histidine and diamino acids is eliminated by a second counter-current extraction under alkaline conditions The quantity of histamine derivative is determined by measuring optical density at 358 m μ in a Beckman spectrophotometer By employing microcells in the spectrophotometer it is possible to determine as little as 0.2 μ g of histamine with an accuracy of $\pm 5\%$ The histamine derivative is very stable and the results are highly reproducible In our application of this method to rabbit whole blood and plasma, the chemical method has given good agreement with bioassays The method is particularly suited for the handling of a large number of samples at one time

Changes in the amount of protamine sulfate required to re-establish *in vitro* clotting of heparinized blood in certain pathologic states CHARLES L MCKEEN, RICHARD M ELGHAMMER and PETER V MOULDER (introduced by J GARROTT ALLEN) *Dept of Surgery, Univ of Chicago, Chicago, Ill* The amount of protamine sulfate required to allow coagulation of standardly heparinized blood is constant in normal human beings and dogs In certain human pathologic conditions, and in artificially produced toxic states in dogs, this protamine sulfate requirement increases In humans, this phenomenon has been observed in leukemia, menorrhagia and in certain patients with coagulation disturbances, otherwise unclassified, it has also been seen following internal and external irradiation and aminopterin and nitrogen mustard therapy It has been produced in dogs by total body irradiation, aminopterin and nitrogen mustard In these instances of changed protamine requirements, clotting times, though usually mildly prolonged, are only occasionally normal and rarely incoagulable This changed protamine requirement is independent of the thrombocyte count Intravenous or intramuscular protamine sulfate and intravenous toluidine blue return the *in vitro* protamine sulfate requirement to, or toward normal

Concurrent estimates of blood volume in rabbits by bleeding and dye methods PAUL L McLAIN, C H WILLIAM RUHE (by invitation) and T K T KRUSE *Dept of Physiology and Pharmacology, School of Medicine, Univ of Pittsburgh, Pittsburgh, Pa* In 20 rabbits, the blood volume by Guthrie's modified Welcker method averaged 126.2 ± 3.21 ml or $4.28 \pm 0.078\%$ of the body weight The animals were bled and simultaneously infused

with saline so as to reduce the circulating hemoglobin as much as possible before failure of the heart. Infusion was continued, with manual pumping of the heart, until the hemoglobin concentration of the effluent was well below 1% of the original. Finally, the limbs were massaged, all large vessels slashed, and the animal drained. All precautions were taken to insure that no significant amount of hemoglobin was left in the animal. In 15 of these animals, plasma volume was estimated concurrently by the dye T-1824. The line established by 3 points on the dye disappearance curve was extrapolated to zero time both rectilinearly and logarithmically. Blood volume was estimated from plasma volume and arterial hematocrit. Ordinary plotting yielded blood volumes $7.23 \pm 0.29\%$ of the body weight, logarithmic plotting $5.67 \pm 0.18\%$. Estimates by the 2 dye methods differed significantly from each other and from those obtained by hemorrhage, and were much less consistent when related to body weight. The average plasma volume obtained by rectilinear plotting exceeded the average whole blood volume estimated by the bleeding technique. The discrepancies between the results of hemoglobin and dye procedures seem too large for explanation by reasonable differences between arterial and 'body' hematocrit, and suggest serious loss of dye from the circulating plasma shortly after injection.

Assay of FSH, ICSH, and luteotrophin in the hypophysectomized rat: clinical applications
 WILLIAM O. MADDOCK (by invitation), EDWIN C. JUNGCK (by invitation), DEMETRIOS A. RIGAS (by invitation), and CARL G. HELLER. *Depts. of Physiology and Medicine, Univ. of Oregon Med. School, Portland, Oregon*. Current methods for assessing gonadotrophins in clinical materials usually indicate whether titers are greater or less than normal, but rarely indicate which of the 3 gonadotrophins are present or predominate. Purified FSH alone does not cause ovarian secretion. FSH plus ICSH stimulates ovarian secretion of estrogen, and the addition of luteotrophin stimulates progesterone secretion. This serves as a basis for the qualitative assay of a mixture of gonadotrophins. Thus, if an unknown extract causes estrogen elaboration from the ovary, FSH and ICSH must be present, if, in addition, progesterone secretion is produced, luteotrophin must also be present in the extract. Estrogen and progesterone secretion can be determined by the effects of these hormones on the immature rat uterus. Alpha-estradiol, administered to castrate or intact immature rats, produced thin-walled, translucent uteri, uniformly ballooned with fluid. Doses of alpha-estradiol 1000 times an effective dose still produced thin-walled, trans-

lucent, fluid-filled uteri. Simultaneous administration of estradiol and progesterone produced thick-walled, opaque uteri, devoid of fluid. Administration of extracts containing predominantly FSH and ICSH to hypophysectomized rats with intact ovaries produced fluid-containing uteri. The same extracts plus luteotrophin produced stimulated uteri devoid of fluid. Administration of extracts of the urine of castrate and normal men have produced uteri devoid of fluid, similar to those produced by estrogen plus progesterone treatment, or by administration of extracts containing FSH, ICSH and luteotrophin. It is concluded that all 3 gonadotrophins are excreted by normal and castrated men.

Possible relationship between cinchophen ulceration of the stomach or duodenum and the choleretic response to cinchophen
 D. F. MAGEE (by invitation), K. S. KIM (by invitation) and A. C. IVER. *Dept. of Clinical Science, Univ. of Illinois College of Medicine, Chicago, Ill.* Cinchophen in dogs is both ulcerogenic and choleretic, whereas in rabbits neither action is observed. The object of this investigation was to determine if this relationship existed in other species. Two sets of experiments were made using cats, rabbits, guinea pigs and rats. 1) *Acute*. Under 'nembutal' anesthesia the common bile duct was cannulated, the gall bladder tied off and the half hourly bile output collected and measured. The differences in volume between the basal flows and those after 100 mg/kg of intravenously administered cinchophen dissolved in N/10 sodium hydroxide were determined. As a test of reactivity intravenous 'decholin' was given. The basal bile flow in cats was 0.5 ml/kg/hr. In guinea pigs 10 ml/kg/hr. Increases after cinchophen of 50% and 60% respectively were observed. The basal flow in rabbits was 4 ml/kg/hr. In rats 2 ml/kg/hr. No choleresis was observed after cinchophen, but it occurred after 'decholin'. 2) *Feeding experiments*. Capsules containing 100 and 200 mg/kg were administered daily. The rats were fed the same per kg dose dissolved in N/10 sodium hydroxide by stomach tube. Equal quantities without cinchophen were given to the control rats. Consistent ulceration was produced only in the cat. Some rabbits and guinea pigs developed gastritis and duodenitis but no ulcers were histologically demonstrable. All the animals, except the rats, fed the sodium salt, died in from one to eight weeks of cinchophen feeding. There is apparently no relation between cinchophen induced choleresis and cinchophen ulcer.

Effect of blood composition on the metabolic activity of the perfused brain in the living cat
 J. MAGNES, R. M. TAYLOR and A. GEIGER (Intro-

duced by H GRUNDFEST) *Dept of Psychiatry, College of Physicians and Surgeons, Columbia Univ, New York City* In continuation of experiments on the metabolism of the perfused cat's brain, attempts were made to facilitate the identification of essential brain metabolites by simplifying the composition of the perfusion blood Perfusion experiments were made with 1) fresh, defibrinated, heparinized beef blood passed through an isolated cat liver for removal of vasoconstrictor substances, 2) the same blood but dialyzed against 0.9% NaCl solution in the cold for 6 days, and reconstituted with electrolytes and glucose, 3) exhaustively washed beef blood corpuscles suspended in a Ringer's solution containing 7% bovine serum albumin All 3 preparations maintain brain functions Preparation (3) shows no vasoconstrictor properties Cerebral oxygen consumption and blood flow were highest with (3) and lowest with (1) with equally good functional activity of the brain The rate of O_2 consumption of the brain is related to the functional activity of the brain as long as reflexes can be elicited, but the actual rate with (1) is between 4-6 ml O_2 consumed by 100 gm brain per minute, while with (3) it is between 7-11 ml Physiologically inactive brains may also show a relatively high O_2 consumption with (3) It is suggested that by washing the blood corpuscles and by substituting a Ringer-albumin solution for plasma an inhibitor of brain metabolism is eliminated

Venous pressure as a factor limiting tolerance of acceleration in the prone position P J MAHER, JR (by invitation), O GAUER (by invitation), E E MARTIN (by invitation), J P HENRY *Aero Medical Lab, Air Materiel Command, Wright-Patterson Air Force Base, Dayton, Ohio* Practical considerations of flight control has stimulated the modification of the full prone position in order to permit better forward vision The torso is raised until the head and chest make an angle of 25° with the horizontal Standard light tests of visual symptoms and electrocardiograph recordings were carried out with 7 unrelaxed subjects in the range of 10-12 g Visual symptoms were absent or mild The electrocardiographic changes were of the same type and degree as those found during positive acceleration of approximately three g in the upright seated posture However, 5 (5) subjects complained of intense pain in the legs or forearms during high accelerations Petechiae were observed in 3 subjects, extending up the arms to the biceps region Venous pressures were measured directly in 2 (2) subjects at 10 g using a vein in the forearm and recording pressures by means of a trimount inductance gauge Pressures of 175 mm Hg were recorded in both cases Since the vertical heart-log distance was 50% greater than the heart-arm dis-

tance of approximately 19 cm, even larger pressures probably occur in the legs These results suggest that pain in the extremities may determine the upper limit of g-tolerance in the prone position

Repeated explosive decompressions DAVID I MAHONEY (introduced by J W WILSON) *Aero Medical Laboratory, Air Materiel Command, Wright-Patterson Air Force Base, Dayton, Ohio* As a result of increasing interest in the explosive decompression of pressurized aircraft, the question has arisen concerning the possibility of producing irreversible damage in individuals exposed to explosive decompressions of moderate intensity repeatedly carried out within a period of several hours In order to test this possibility, a series of experiments was conducted using dogs as subjects Thirteen test animals were used during the study and were subjected to no surgical procedure The animals singly or in pairs, were placed in a small cabin which was located within a low-pressure chamber The small chamber was held at ground level until the large chamber was evacuated to the altitude required to give the desired pressure differential (6.55 psi) A membrane of several layers of brown wrapping paper covering a $10\frac{1}{2}$ in diameter orifice in the small chamber was broken at the desired time of decompression The chamber was then immediately brought to ground level to preclude any effects of hypoxia The time for all explosions varied between 0.120 to 0.126 seconds The total time elapsing during a series of 7 explosive decompressions on each dog ranged from 45 to 75 minutes There was no evidence of ill effects from the explosive decompressions in any of the dogs either immediately after the decompressions or during a subsequent observation period of 2 weeks The lack of evidence of irreversible damage in this series plus the results of Hitchcock *et al* (*J Av Med* 17, 6, 1946) lead to the conclusion that repeated explosive decompressions of moderate intensity are not a significant factor that may lead to mortality in dogs

Behavior of actomyosin threads SAMUEL MALLOV (by invitation) and JANE SANDS ROBB *Dept of Pharmacology, Syracuse Univ College of Medicine, Syracuse, N Y* Actomyosin from skeletal muscle of the rabbit, dog and guinea pig has been extracted and also purified by methods described by Szent Gyorgyi Mincing favors greater output in shorter time but renders further separation more difficult Purified actomyosin is stable for several weeks Threads can be drawn but in contrast to unpurified threads, these respond to ATP only if calcium and/or magnesium ions are added and even then the degree of shortening is less Images of these contracting threads have been projected to a screen and moving pictures taken

Movement, generally beginning at the ends, is preceded by increase in density. As shortening proceeds, spiraling occurs. It is our impression that threads drawn into about 0.015% magnesium chloride develop tighter spirals (than is the case when drawn in potassium chloride) and that shortening is followed by partial relaxation. Behavior of threads drawn into 1:2,000,000 solution of crystalline cardiac glycoside is standard. If the glycoside is mixed with actomyosin and allowed to stand for an hour or two before threads are drawn, considerable relaxation precedes contraction, spiraling is pronounced and maximum shortening appears. We have not been able to demonstrate activation by barium which was attempted because of the report of Deutsch and Lundin that it is barium and not ATP which is responsible for automatic cardiac activity. Using standard methods, less actomyosin can be extracted from a given amount of heart muscle, it is less viscous, forms threads less well, and these in spite of being thinner are less reactive than threads composed of skeletal actomyosin.

Intestinal Perfusion in a patient with chronic uremia N. S. R. MALUF *Surgical Research Unit, Brooke General Hospital, Fort Sam Houston, Texas*. Intestinal perfusion was tested in a severely uremic patient by the triple-bore tube. Thirty-one liters of 2 to 2.27% anhydrous sodium sulfate were dripped in 24 hours for intestinal and, then, gastric irrigation. The small quantity of liquid which regurgitated into the stomach while the intestine was being perfused was sucked through a gastric tube admitted through the other nostril, this completely prevented vomiting. Inevitable leakage through the anus was through a rubber-tube (1.6 cm O.D., 1.1 cm I.D.) inserted into the rectum and attached to the buttocks by adhesive tape, this almost totally prevented soiling. Perfusion averaged 22 cc/min, which was much slower than previously used in non-uremic patients (Maluf, 1948, *Federation Proc.* 7:77, 1948, *J. Urology* 60:307, 1948). Because of the high plasma-urea and slow perfusion, the urea clearance was only 1.8 cc/min. Nevertheless, 50 gm of urea were extracted in 24 hours and plasma-urea fell from 357 to 246 mg/100 cc in spite of intestinal perfusion occupying only 10.5 hours, the remaining 13 hours being exclusively gastric irrigation. Intestinal irrigation was at least 8 times more effective in eliminating urea than gastric. Edema, ascites and weight dropped markedly in spite of 6.5 liters liquid iv. Elevated arterial pressure fell and the patient was mentally improved. 662 mg of Ca, 2.3 gm of K and 48.3 gm of Cl were lost in the perfusate. Plasma Cl (as NaCl) fell from 574.6 to

523.9 mg/100 cc. Besides dextrose, water and vitamins, 15 gm NaCl and 4 gm calcium gluconate were given intravenously.

Inactivation of thromboplastin by serum F. D. MANN and MARGARET HURN (Introduced by T. B. MAGATH) *Division of Clinical Labys, Mayo Clinic, Rochester, Minn.* Most of the thromboplastic activity of extract of rabbit brain disappeared on incubation with an equal volume of human serum for 1 hour at 37°C. By dilution and acidification of the mixture, thromboplastin was precipitated and recovered in active form. Decalcification of the serum with oxalate largely prevented the inactivation of thromboplastin. Over the pH range 7 to 8, alkali decidedly favored and acid inhibited the inactivation of thromboplastin by serum. A rather similar pH effect was observed for conversion of prothrombin to thrombin in the two-stage system.

Effect of dibenamine on ventricular fibrillation following sudden coronary occlusion G. W. MANNING, R. C. A. F. *Institute of Aviation Medicine, Toronto, and the Dept of Physiology, Univ of Western Ontario, Ontario, Canada*. In 75% of normal conscious dogs sudden occlusion of the left circumflex coronary artery results in ventricular tachycardia followed by ventricular fibrillation and death. It has been shown that cardiac sympathetic denervation and the sympatholytic drug, dihydroergotamine, significantly inhibits the development of this fatal ectopic rhythm. In view of the results reported by Nickerson *et al.*, with dibenamine, the effect of this sympathetic blocking agent on the immediate mortality due to ventricular fibrillation was studied. Under anesthesia a loose ligature was placed around the left circumflex coronary artery. Dibenamine (20 mg/kg) was given intravenously in 250 cc of normal saline, over a period of $\frac{1}{2}$ to $\frac{3}{4}$ of an hour. ECG and blood pressures, in some cases, were recorded before and after dibenamine and before, during and after ligation. Sudden ligation in the conscious dog was carried out the following day by traction on the ends of the ligature which had been brought out through the chest wall (at a tangent to the heart). In the ECG the most constant changes noted were an increase in the heart rate, and increase in amplitude of the T and P waves and a reduction of the amplitude of the R waves occurred in some experiments following the injection of dibenamine. Following ligation of the left circumflex the usual sequence of events was noted in the ECG. There was a progressive elevation of the S-T segments, frequent extrasystoles and bouts of ventricular tachycardia followed by fatal ventricular fibrillation in 55% of the animals within the 24-hour period following ligation—(all occurred within the first 12 minutes

except in one animal which died in 10-12 hours following ligation) In the control series the same changes were observed and 75% of the animals died in ventricular fibrillation within the 24-hour period Although an insignificant reduction in mortality occurred, the frequency of extrasystoles and ventricular tachycardia appeared to be no different from that seen in untreated control animals It would appear from these experiments that dibenamine is not an effective agent in preventing the fatal ectopic cardiac rhythm which occurs following sudden coronary occlusion in the conscious dog

Characteristics of the thigh muscles with a double action J E MARKEE and MAUDE WILLIAMS (by invitation) *Dept of Anatomy, Duke Univ School of Medicine, Durham, N C and Division of Physiology, Womens College of Univ North Carolina, Greensboro, N C* Previously, evidence was presented that muscles which pass over both the knee and hip function as double muscles, one part shortens to move the hip, another part shortens to move the thigh This different participation of the separately innervated areas of the biceps femoris, semitendinosus, semimembranosus, rectus femoris, sartorius and gracilis occur during 1) direct stimulation of the nerve branches, 2) reflex flexion and crossed extension elicited in decerebrate preparations, and 3) flexion and extension induced by cortical stimulation In the present investigation, evidence is presented indicating that these thigh muscles which act as double muscles possess the functional characteristics of simple flexor and extensor muscles That is, one part of the biceps femoris flexes the knee and resembles a simple flexor muscle in that it fatigues rapidly and develops less tension per unit of weight In addition the development of effective tension occurs through a longer proportion of the range of shortening of the fibers On the other hand, the part of the biceps femoris which extends the hip resembles muscles which are simple extensors in that this part fatigues less rapidly and develops more tension per unit of weight In addition the development of tension is more dependent on the length of the fiber in the extensor portion of the muscle The flexor and extensor portions of the semitendinosus and gracilis respectively possess these flexor and extensor characteristics

Specific resistance of regenerating Dugesia in different media and the electrical work of polarity control GORDON MARSH and JEAN DIMMITT (by invitation) *Zoological Labys, State Univ of Iowa, Iowa City, Ia* Pieces of *Dugesia tigrina*, regenerated 3 days in solutions of different specific resistance, were transferred individually to a chamber 0.149 mm deep, which confined them at virtually uniform thickness The voltage difference

producing constant current with and without the piece, divided by that current, gives the difference in resistance, under the two conditions, of a chamber segment of length equal to the piece During current flow the orientation, geometric shape and critical dimensions of the piece were determined, enabling calculation of the 'specific resistances' (ohm-cm at 24°C)

SP RES MEDIUM	SP RES DUGESIA	NO CASES	QO ₂
923	1682 ± 178	9	150-474
2280	1587 ± 203	10	140-400
5180	2370 ± 330	12	122-349
10,900	4538 ± 451	13	113-332

Midpieces showed the highest and posterior pieces the lowest resistance, with significance doubtful Resistance was independent of current strength, which was usually that capable of reversing polarity The previously demonstrated constancy of potential gradient producing a given morphogenetic effect in media of varying resistance, gains significance from the fact that the internal current varies The electrical energy expended in a 1 mm³ piece regenerating 4 days in the current varies from 0.06 to 0.25 cal, depending upon specific resistance and potential gradient (regressive bipolarity 1.78 volts/cm, reversal 2.17 volts/cm) Assuming 1.05 for piece density and 5 cal/cc caloric equivalent for oxygen, these energies would represent the QO₂'s above if provided by the regenerating material All lie within the limits of published data

Purification and possible histochemical localization of renin JOHN MARSHALL (by invitation) and G E WAKERLIN *Depts of Physiology and Pathology, Univ of Illinois College of Medicine, Chicago, Ill* Purified hog renin was prepared by an extension of the ethanol fractionation method previously described (*Federation Proc* 7 78, 1948), with a resulting yield of 22,000 DU (Goldblatt) at a purity of 125 DU/mg N This preparation gave a polysaccharide reaction to the Hotchkiss technique (*Arch Biochem* 16 131, 1948) Accordingly, sections of 22 dog kidneys of widely varying renin content were stained by the Hotchkiss method Renin content varied from 0 to 22 DU/gm The results showed a good correlation between the renin content and granules containing glycoprotein in the juxtaglomerular apparatus The solubility of the glycoprotein granules in the juxtaglomerular apparatus of tissues prepared by freezing and drying was compared with that of dog renin Using the same procedures employed for the fractional separation of purified renin, it was found that the solubilities of both substances mentioned above corresponded Both were insoluble at 0°C, ionic strength 0.005, pH 5.10, at 20% ethanol con-

centrations or higher, and were soluble at lower ethanol concentrations

Presence of multiple cortical foci in the primary sensory projection systems of the cat WADE H MARSHALL *National Institutes of Health, Bethesda Md* In connection with work on the recovery cycle of the somatic sensory system of the cat, this author located 3 cortical regions at which responses occurred following tactile stimulation of the contralateral forefoot. These regions were specified in a joint paper on cortical reactions (Marshall *et al*, *J Neurophysiol* 4 1, 1941) Adrian (*J Physiol* 100 159, 1941) has questioned the presence of 3 such regions. Woolsey, in his published work on mapping the somatic sensory cortex of the cat, has discussed only 2 of these regions. One, the sensory region of Campbell, he has logically labeled *Somatic I*, the other, the anterior ectosylvian region, he has labeled *Somatic II*. The question of the third he does not discuss. The point has been reexamined and the author's original findings have been confirmed. There is a third area extending laterally from the region of the junction of ansate and lateral sulci across the posterior part of the *Somatic I* face area toward the anterior ectosylvian *Somatic II*. Multiple primary projection foci are not peculiar to the somatic sensory system. The visual system in the cat contains 2 demonstrable areas in addition to the striate and contiguous boundary region. One of these is in the posterior suprasylvian gyrus. The other region is in the middle ectosylvian gyrus extending medially across the suprasylvian sulcus onto the dorsal surface of the suprasylvian gyrus.

Suppressor action on primary sensory projection reactions WADE H MARSHALL *National Institutes of Health, Bethesda, Md* Previous work by the author has shown significant bilateral inter-fiber interaction in optic tract and radiations of the cat. It was considered desirable to determine if cortical suppression (suppressor reaction of Leão, and Leão and Morrison) would exercise a suppressor action on the radiation terminations. A decision on this question necessarily involves simultaneous observations on the primary relay nuclei of the thalamus. This has been done in the geniculostriate system of the rabbit and cat. In the rabbit no change has been observed in geniculate reactions or in the radiation spike complex as recorded on, in or under the cortex. The decision in the cat is not yet clear because of the difficulty in eliciting regular and repeated suppressor cycles in that animal. The radiation amplitude has shown reduction in some experiments accompanied by a reduction in lateral geniculate postsynaptic reaction. However, it is certain, in the case of the cat, that radiation amplitude is reduced not more than 10%, if any such reduction occurs due to the suppressor reaction. In both cat and rabbit the suppressor

reaction reduces and eliminates the primary surface positive cortical components. The first cortical synaptic reaction is the last to be completely eliminated. In the rabbit it is certain that the reaction affects only the purely cortical events. Subcortical or intracortical block of afferent impulses does not occur, only the primary cortical events subsequent to radiation activity are affected.

Static assessment of the relative efficiency of anti-G suits E E MARTIN (by invitation), G SCHROER (by invitation), J P HENRY *Aero Medical Lab, Air Materiel Command, Wright-Patterson Air Force Base, Dayton, Ohio* Attempts to estimate the effectiveness of anti-G suits while at rest by measuring the changes they induce in blood pressure have shown increments proportionate to the relative efficiency of these devices during acceleration. (Air Materiel Command Memorandum Report MCREXD-689-2C, dated July 1948) The results suggest that tests of G-suit efficiency could be devised which do not require the use of a human centrifuge. With this end in view, 3 further measurements were made: venous pressure, vital capacity and teeter board weight shift. Venous pressure was measured at the antecubital fossa when the legs only of the G-3A, G-4A, and G-5 suits were inflated. A teeter board was employed to measure the weight shift induced by the inflation. The changes in vital capacity were measured under the same conditions. Eight series of 3 tests each were carried out on 6 subjects. The following table shows the changes induced by suit inflation.

	G-3A	G-4A	G-5
Venous pressure increase (cm H ₂ O)	0.3 ± 0.2	1.9 ± 0.6	4.3 ± 0.5
Vital capacity decrease (cc)	250 ± 60	325 ± 70	400 ± 60
Teeter Board weight shift (pounds)	0.3 ± 0.1	0.4 ± 0.2	0.5 ± 0.3

These differences are qualitatively confirmed by the results of tests of these suits on the human centrifuge. In the G-3A suit mean protection as estimated from blood pressure changes was 1.0G, G-4A suit 2.2G, and the G-5 suit 2.3G.

Occurrence of potassium U/P ratios lower than 1.0 F MATEER (by invitation), L GREENMAN (by invitation), J H PETERS (by invitation), R C GOW (by invitation), and T S DANOWSKI *Dept of Research Medicine, Univ of Pittsburgh School of Medicine, Pittsburgh, Penna* It has been demonstrated that during periods of reduced or absent intake of food and water the urinary excretion of sodium decreases to zero while potassium continues to be present in the urine (*J Clin Invest* 23

except in one animal which died in 10-12 hours following ligation) In the control series the same changes were observed and 75% of the animals died in ventricular fibrillation within the 24-hour period Although an insignificant reduction in mortality occurred, the frequency of extrasystoles and ventricular tachycardia appeared to be no different from that seen in untreated control animals It would appear from these experiments that dibenamine is not an effective agent in preventing the fatal ectopic cardiac rhythm which occurs following sudden coronary occlusion in the conscious dog

Characteristics of the thigh muscles with a double action J E MARKEE and MAUDE WILLIAMS (by invitation) *Dept of Anatomy, Duke Univ School of Medicine, Durham, N C and Division of Physiology, Womens College of Univ North Carolina, Greensboro, N C* Previously, evidence was presented that muscles which pass over both the knee and hip function as double muscles, one part shortens to move the hip, another part shortens to move the thigh This different participation of the separately innervated areas of the biceps femoris, semitendinosus, semimembranosus, rectus femoris, sartorius and gracilis occur during 1) direct stimulation of the nerve branches, 2) reflex flexion and crossed extension elicited in decerebrate preparations, and 3) flexion and extension induced by cortical stimulation In the present investigation, evidence is presented indicating that these thigh muscles which act as double muscles possess the functional characteristics of simple flexor and extensor muscles That is, one part of the biceps femoris flexes the knee and resembles a simple flexor muscle in that it fatigues rapidly and develops less tension per unit of weight In addition the development of effective tension occurs through a longer proportion of the range of shortening of the fibers On the other hand, the part of the biceps femoris which extends the hip resembles muscles which are simple extensors in that this part fatigues less rapidly and develops more tension per unit of weight In addition the development of tension is more dependent on the length of the fiber in the extensor portion of the muscle The flexor and extensor portions of the semitendinosus and gracilis respectively possess these flexor and extensor characteristics

Specific resistance of regenerating Dugesia in different media and the electrical work of polarity control GORDON MARSH and JEAN DIMMITT (by invitation) *Zoological Labys, State Univ of Iowa, Iowa City, Ia* Pieces of *Dugesia tigrina*, regenerated 3 days in solutions of different specific resistance, were transferred individually to a chamber 0.149 mm deep, which confined them at virtually uniform thickness The voltage difference

10,900	4538 ± 451	13	113-332

Midpieces showed the highest and posterior pieces the lowest resistance, with significance doubtful Resistance was independent of current strength, which was usually that capable of reversing polarity The previously demonstrated constancy of potential gradient producing a given morphogenetic effect in media of varying resistance, gains significance from the fact that the internal current varies The electrical energy expended in a 1 mm³ piece regenerating 4 days in the current varies from 0.06 to 0.25 cal, depending upon specific resistance and potential gradient (regressive bipolarity 1.78 volts/cm, reversal 2.17 volts/cm) Assuming 1.05 for piece density and 5 cal/cc caloric equivalent for oxygen, these energies would represent the QO₂'s above if provided by the regenerating material All lie within the limits of published data

Purification and possible histochemical localization of renin JOHN MARSHALL (by invitation) and G E WAKERLIN *Depts of Physiology and Pathology, Univ of Illinois College of Medicine, Chicago, Ill* Purified hog renin was prepared by an extension of the ethanol fractionation method previously described (*Federation Proc* 7: 78, 1948), with a resulting yield of 22,000 DU (Goldblatt) at a purity of 125 DU/mg N This preparation gave a polysaccharide reaction to the Hotchkiss technique (*Arch Biochem* 16: 131, 1948) Accordingly, sections of 22 dog kidneys of widely varying renin content were stained by the Hotchkiss method Renin content varied from 0 to 22 DU/gm The results showed a good correlation between the renin content and granules containing glycoprotein in the juxtaglomerular apparatus The solubility of the glycoprotein granules in the juxtaglomerular apparatus of tissues prepared by freezing and drying was compared with that of dog renin Using the same procedures employed for the fractional separation of purified renin, it was found that the solubilities of both substances mentioned above corresponded Both were insoluble at 0°C, ionic strength 0.005, pH 5.10, at 20% ethanol con-

centrations or higher, and were soluble at lower ethanol concentrations

Presence of multiple cortical foci in the primary sensory projection systems of the cat WADE H MARSHALL *National Institutes of Health, Bethesda Md* In connection with work on the recovery cycle of the somatic sensory system of the cat, this author located 3 cortical regions at which responses occurred following tactile stimulation of the contralateral forefoot. These regions were specified in a joint paper on cortical reactions (Marshall *et al*, *J Neurophysiol* 4 1, 1941) Adrian (*J Physiol* 100 159, 1941) has questioned the presence of 3 such regions. Woolsey, in his published work on mapping the somatic sensory cortex of the cat, has discussed only 2 of these regions. One, the sensory region of Campbell, he has logically labeled *Somatic I*, the other, the anterior ectosylvian region, he has labeled *Somatic II*. The question of the third he does not discuss. The point has been reexamined and the author's original findings have been confirmed. There is a third area extending laterally from the region of the junction of ansate and lateral sulci across the posterior part of the *Somatic I* face area toward the anterior ectosylvian *Somatic II*. Multiple primary projection foci are not peculiar to the somatic sensory system. The visual system in the cat contains 2 demonstrable areas in addition to the striate and contiguous boundary region. One of these is in the posterior suprasylvian gyrus. The other region is in the middle ectosylvian gyrus extending medially across the suprasylvian sulcus onto the dorsal surface of the suprasylvian gyrus.

Suppressor action on primary sensory projection reactions WADE H MARSHALL *National Institutes of Health, Bethesda, Md* Previous work by the author has shown significant bilateral inter-fiber interaction in optic tract and radiations of the cat. It was considered desirable to determine if cortical suppression (suppressor reaction of Leão, and Leão and Morrison) would exercise a suppressor action on the radiation terminations. A decision on this question necessarily involves simultaneous observations on the primary relay nuclei of the thalamus. This has been done in the geniculostriate system of the rabbit and cat. In the rabbit no change has been observed in geniculate reactions or in the radiation spike complex as recorded on, in or under the cortex. The decision in the cat is not yet clear because of the difficulty in eliciting regular and repeated suppressor cycles in that animal. The radiation amplitude has shown reduction in some experiments accompanied by a reduction in lateral geniculate postsynaptic reaction. However, it is certain, in the case of the cat, that radiation amplitude is reduced not more than 10%, if any such reduction occurs due to the suppressor reaction. In both cat and rabbit the suppressor

reaction reduces and eliminates the primary surface positive cortical components. The first cortical synaptic reaction is the last to be completely eliminated. In the rabbit it is certain that the reaction affects only the purely cortical events. Subcortical or intracortical block of afferent impulses does not occur, only the primary cortical events subsequent to radiation activity are affected.

Static assessment of the relative efficiency of anti-G suits E E MARTIN (by invitation), G SCHROER (by invitation), J P HENRY *Aero Medical Lab, Air Materiel Command, Wright-Patterson Air Force Base, Dayton, Ohio* Attempts to estimate the effectiveness of anti-G suits while at rest by measuring the changes they induce in blood pressure have shown increments proportionate to the relative efficiency of these devices during acceleration. (Air Materiel Command Memorandum Report MCREXD-689-2C, dated July 1948) The results suggest that tests of G-suit efficiency could be devised which do not require the use of a human centrifuge. With this end in view, 3 further measurements were made: venous pressure, vital capacity and teeter board weight shift. Venous pressure was measured at the antecubital fossa when the legs only of the G-3A, G-4A, and G-5 suits were inflated. A teeter board was employed to measure the weight shift induced by the inflation. The changes in vital capacity were measured under the same conditions. Eight series of 3 tests each were carried out on 6 subjects. The following table shows the changes induced by suit inflation.

	G-3A	G-4A	G-5
Venous pressure increase (cm H ₂ O)	0.3 ± 0.2	1.9 ± 0.6	4.3 ± 0.5
Vital capacity decrease (cc)	250 ± 60	325 ± 70	400 ± 60
Teeter Board weight shift (pounds)	0.3 ± 0.1	0.4 ± 0.2	0.5 ± 0.3

These differences are qualitatively confirmed by the results of tests of these suits on the human centrifuge. In the G-3A suit mean protection as estimated from blood pressure changes was 1.0G, G-4A suit 2.2G, and the G-5 suit 2.3G.

Occurrence of potassium U/P ratios lower than 1.0 F MATEER (by invitation), L GREENMAN (by invitation), J H PETERS (by invitation), R C GOW (by invitation), and T S DANOWSKI *Dept of Research Medicine, Univ of Pittsburgh School of Medicine, Pittsburgh, Penna* It has been demonstrated that during periods of reduced or absent intake of food and water the urinary excretion of sodium decreases to zero while potassium continues to be present in the urine (*J Clin Invest* 23

807, 1944) This diminished excretion of sodium has been interpreted as a salt-conserving response preventing sodium depletion. The continued urinary loss of potassium is often associated with transfers of potassium out of cells, in part with the negative balance of protein and in part with dehydration (*J Clin Invest* 23 93, 1944). These transfers may not occur during renal suppression (*J Clin Invest* 27 74, 1948). If urine is elaborated, excretion of potassium continues, thereby permitting movement of cellular potassium without production of toxic extracellular levels. This urinary loss of potassium frequently continues even in the presence of hypokalemia and is one of the important routes of loss resulting in potassium depletion (*J Clin Invest* 27 557, 1948). This would suggest that the kidney is incapable of conserving potassium when body stores of this cation are depleted. Our studies of subjects with hypokalemia indicate, however, that the urinary loss of potassium may sometimes be markedly reduced, resulting in potassium U/P ratios lower than 1.0. In the 6 instances in which this was observed, 3 patients recovering from diabetic acidosis and 3 infants with protracted vomiting, the decrease in urine potassium concentrations below those in serum did not necessarily appear coincidental with hypokalemia but rather became evident after several days of persistent deficits of potassium.

Measurement of renal venous pressure in normal man and in patients with congestive heart failure M. HARRISON MAXWELL, ERNEST S. BREED and IRVING L. SCHWARTZ (introduced by HOMER W. SMITH) *Dept of Physiology, New York Univ College of Medicine, New York City*. Direct measurements of renal venous pressure were recorded in 7 normal male subjects and in 5 male patients in severe chronic congestive heart failure by means of a no. 10 Courmand radio-opaque catheter passed under fluoroscopy from an antecubital vein into the right renal vein. A saline manometer was used with repeated elevation above equilibrium. The normal subjects were all supine, the cardiacs supine or semi-recumbent. An arbitrary zero point of 10 cm above the table top was assumed in all cases. Lateral X-rays taken on 6 subjects showed the tip of the catheter *in situ* varied from 5.3 to 15.2 cm above the table top, with an average of 9.9. Since the true zero point coincided so closely with the assumed one, no corrections were necessary. The renal venous pressure in normal subjects ranged from 13.0 to 19.8 cm of saline, with an average of 15.4; in failure the pressure ranged from 16.5 to 28.0 cm, with an average of 24.3. In 6 normal patients and 3 cardiac patients, right atrial pressures were recorded during withdrawal of the catheter, the zero point being taken as 5 cm below the angle of Louis. The normal subjects had pressures varying from 0 to 5.3 cm of saline, with an

average of 2.5. The cardiac subjects had pressures varying from 11.0 to 15.0 cm, with an average of 13.0.

Determination of blood flow through the finger at high rates of flow JERE MEAD and ROBERT C. SCHOENFELD (introduced by H. S. BELDING) *The Quartermaster Corps, Climatic Research Laboratory, Lawrence, Mass*. When venous occlusion is accomplished in the finger without occlusion artifact, the slope of the tracing at the instant following occlusion depicts a volume rate of change which is the algebraic sum of two components: 1) the volume rate of change varying through each cardiac cycle to produce the finger pulse, 2) the volume rate of change which relates directly to the obstruction of outflow from the finger. If the instantaneous pulse slope derived from corresponding points on preceding pulse waves is subtracted algebraically from the initial occlusion slope, the volume rate of change of the finger independent of the pulse volume rate of change is obtained. This represents the instantaneous rate of blood flow through the finger.

Utilizing an electric solenoid air valve 'triggered' through a variable time delay circuit by the QRS potential of the ECG, venous occlusions were produced at specific points through the cardiac cycle, and variations in blood flow during the finger pulse cycle were studied. In vasodilated individuals the rate of flow in the terminal phalanx of the finger increased during the rising phase of the pulse to maximum values as high as 200 cc/100 cc of tissue/minute, and decreased during the diminishing phase of the pulse to roughly $\frac{1}{4}$ of the maximum flow. Average flows over the pulse cycle as high as 160 cc/100 cc of tissue/minute were computed. The markedly pulsatile character of blood flow through the terminal phalanx of the finger suggests that a considerable part of the finger's blood flow may be through the arteriovenous shunts described in this region.

Effect of carbohydrate on starvation metabolism in the presence of a high caloric deficit G. W. MELLINGER (introduced by J. W. HEIM) *Aero Medical Laboratory, Air Materiel Command, Wright-Patterson Air Force Base, Dayton, Ohio*. During a study of airborne survival ratios, metabolic observations were made to determine the effect of feeding 100 gm of carbohydrate daily on the body protein loss, ketosis, water balance and physical efficiency of men performing strenuous physical exertion in a cold environment. Two subjects resided continuously in an all-weather chamber at -29°C for 6 days. During this period they expended 4000 to 4500 calories while ingesting only 100 gm of carbohydrate (400 cal) daily. Clothing consisted of an experimental arctic clothing assembly having a clo value of approximately four. Sleeping bags were used at night. As a control, the subjects performed a similar

amount of work for 6 days while fasting. The serum carbon dioxide, organic acids, urinary ammonia and titratable acidity showed that there was a moderate degree of ketosis during the fasting experiments, but that all but slight changes were prevented by carbohydrate in amounts of 100 gm daily. Body protein loss was spared to the extent of 40-50% of the fasting loss when the carbohydrate was given. The water balance was favorably affected by 100 gm of carbohydrate as was shown by the marked reduction in the minimum urine water and total urine solutes, and by the moderate reduction in the minimum water intake. While maximum efficiency was not maintained during the experiments, the subjects were in sufficiently good condition at the end of the 6 days to perform tasks necessary for survival.

Further studies on complete parenteral alimentation. H. C. MENG (introduced by HOWARD J. CURTIS) *Dept. of Physiology, Vanderbilt Univ. Medical School, Nashville, Tenn.* A fat emulsion has been prepared for intravenous feeding (described elsewhere), and the present report describes the nutritional value and toxicity of this emulsion in dogs and rabbits. In the control period, 5 adult dogs were fed a complete basal diet by mouth. Immediately following this they were fed entirely by vein for 4 weeks and then killed for pathological examination. Four were given the same diet as during the control period, of which 34% of the calories were from fat, while the 5th dog received the same carbohydrate and protein diet but without the fat. The dogs on the complete diet were normal and healthy in all respects, and all laboratory findings were negative. The dog on the fat-free diet lost 14% of his weight and was very weak and apathetic. The injection of relatively large amounts of the emulsion in rabbits produced no appreciable pyrogenic effects. Further, the daily injection in rabbits of large quantities of both the emulsion and the emulsifying agents for as long as 4 weeks produced no deleterious effects. As tested in rabbits, it has been found that the emulsion is not antigenic. It is concluded that this emulsion is non-toxic and that the body is capable of utilizing fat in this form.

Physiologic effects of bilateral simultaneous removal of Brodmann cytoarchitectural areas in the human. FRED A. METTLER *Dept. of Neurology, College of Physicians and Surgeons, Columbia Univ., New York City.* In the 'combined-operations' study, known as the Columbia-Greystone Project, the physiology of 23 psychotic individuals from whom localized areas of frontal cortex were simultaneously, bilaterally removed, was studied pre- and postoperatively. Data were collected relating to formed elements of the blood, blood chemistry, blood pressure, body weight, gastrointestinal motility, electroencephalography, vision,

audition, somatosensation, reflex state, motor function and higher cerebral functions. The studies were begun 40 days prior to operation and have been continued, when pertinent, for over 1½ years. In certain physiologic fields (basal metabolism, somatic activity) no data could be obtained.

Bilateral removal of Brodmann areas of granular frontal cortex or of various combinations of these produced no definite, enduring, physiologic changes in any of the fields noted above except, in some cases, electroencephalography. Temporary effects were short-lived and generally not of such a nature as to demonstrate a causal effect between the nature of the ablation and the physiologic disturbance. Aphasia does not follow removal of area 44. The effects of removal of agranular cortex were also relatively unproductive. As previously reported for the simian (by Hines *et al.* and by the present author) cortex of area 6 may be removed without evoking evidence of spasticity. Neither does such a procedure necessarily produce forced grasp in the human.

III Effect of low barometric pressure on the brains of five vertebrates. BERNARD METZ (introduced by CHARLES G. WILBER) *Biological Lab., Fordham Univ., New York City.* Five vertebrates (the goldfish, *Carassius auratus*, the frog, *Rana pipiens*, the painted turtle, *Chrysemys picta*, the pigeon, *Columba livia*, and the Wistar rat, *Rattus norvegicus*) were subjected to simulated altitudes of 18,000, 33,000, 48,000, 64,000 and 90,000 feet, respectively. The survival rates, behavior and effects upon the vascular tissue and nervous elements of the brain were studied. The methods used and the survival rates were previously reported by Metz and Wilber (*Anat. Rec.* 99: 676, 1947; 101: 738, 1948; in the latter paper, survival rates for rats at 48,000 feet should be amended to read 66.2 seconds, not 66.2 minutes). Concerning the effects upon the brain, the most striking pathological changes are the intracranial hemorrhages (table 1). Visible damage to the nervous elements was noted only in a few cases. This nerve cell damage, as in the case of the hemorrhages, was widely dispersed in the optic lobes (in the fish, frog and turtle), cerebrum, cerebellum and medulla oblongata.

Table 1. Numbers of cases showing pathological changes

A. TIAL	NO. OF EXPERI- MENTAL A. TIALS	HEMOR- RHAGES	NERVE CELL DAMAGE
Goldfish	50	36	5
Frog	50	23	3
Turtle	50	25	9
Pigeon	50	21	4
Rat	50	27	5

The fact that there was only a small number of cases showing nerve cell damage does not imply that the nervous elements of the brains of the other experimental animals escaped unharmed. There exists the possibility that the changes which may have occurred are not morphological in nature, but rather are biochemical phenomena at a sub-microscopic level (Page *Chemistry of the Brain*, 1937).

Renal hemodynamics during short and long periods of salt poor albumin administration
ALEXANDER J. MICHIE (by invitation), NICHOLAS S. GIMBEL (by invitation) and CECILIA RIEGEL Harrison Dept of Surgical Research, Schools of Medicine, Univ of Pennsylvania, Philadelphia, Penna. The daily intravenous administration of salt-poor albumin to normal subjects caused a progressive expansion in plasma volume, an enlargement in extracellular fluid volume, an increasing venous pressure, a dilation of the roentgen heart shadow and an engorgement of the liver. The distended plasma volume produced a renal hyperemia and relaxation of efferent arteriolar tone. In renal hyperemia absence of a maximal filtration rate might be indicative of some systemic circulatory derangement. One week after termination of the albumin therapy and in the presence of a continued renal hyperemia the filtration rate increased as plasma volume and venous pressure dropped. Five months later the same subject was given 75.0 gm of salt-poor albumin intravenously in 20 minutes. Renal plasma flow was raised 700 cc/min, and filtration rate showed a maximal increase of 40.0 cc/min above the control values. The filtration fraction was decreased to a low of 0.117. The protracted renal hyperemia apparently led to an increase in T_{mPAH} . As the albumin was slowly metabolized during the 2- to 3-week experimental period, these subjects approached a protein-free diet, which in the experimental animal tends to diminish filtration rate, renal plasma flow and tubular mass. In the acute experiment 75.0 gm of albumin caused no significant change in T_{mPAH} or T_{mG} . The unchanged T_{mG} shows that no glomerular arteriovenous shunts were opened by this hyperemia and that the diminution in the PAH extraction ratio is probably due to increased albumin binding.

Influence of adrenaline on the cardiodepressor effect of acetylcholine and the vagus nerve
S. MIDDLETON and J. TALESNIK (introduced by HAROLD C. WIGGERS) *Physiological Institute, Univ of Chile, Santiago, Chile*. In isolated guinea pig and cat hearts adrenaline perfusion with concentrations of 3–20 $\mu\text{g/l}$ produced a marked increase of submaximal cardiodepressor (negative chrono and inotropic) effects of acetylcholine (0.05–0.5 μg). This augmenting effect was less marked with concentrations of adrenaline of 30 $\mu\text{g/l}$ or more, while concentrations of 1 $\mu\text{g/l}$ or less

were ineffective. The effects of adrenaline were not influenced when nicotine in concentrations of 1–2 $\mu\text{g/l}$ was added to the perfusion fluid. This would indicate that adrenaline acts by modifying the sensitivity of the cardiac effectors (peripheral effect), an influence on the intracardiac ganglia should be discarded. Adrenaline did not influence the cardiodepressor action of KCl.

In 28 experiments performed on isolated cat hearts, perfusion with adrenaline in concentrations of 0.05–0.1 $\mu\text{g/l}$ produced a very marked increase of submaximal cardiodepressor effects induced by electrical excitation of the vagus nerves. Smaller concentrations of adrenaline were ineffective. Concentrations of 1 $\mu\text{g/l}$ or more produced a decrease of the vagal effects. In view of the above-described results with nicotine the effect of high concentrations of adrenaline are probably due to a blocking action on the intracardiac ganglia. Eight experiments were performed on frogs, in which perfusion of the isolated heart (Straub's heart with Krayner cannula) with adrenaline (0.5–1 $\mu\text{g/l}$) produced a marked increase of the cardiodepressor effect of the vagus.

Influence of the cardiac sympathetic nerves on the cardiodepressor action of the vagus nerve
S. MIDDLETON and J. TALESNIK (introduced by HAROLD C. WIGGERS) *Physiological Institute, Univ of Chile, Santiago, Chile*. Twenty-five experiments were performed on isolated cat hearts, which were removed with the vagi and part of the surrounding mediastinal structures (including the stellate ganglia and adjacent thoracic sympathetic chains) attached. The preparations were made in such a way that, when desired, the stellate ganglion could also be perfused. In various experiments the vagi or the preganglionic or postganglionic sympathetic nerves were electrically stimulated. It was observed that stimulation of the cardiac pre- or postganglionic sympathetics in 6 experiments induced increase of submaximal cardiodepressor effect of the vagus. In 8 experiments, however, the sympathetic produced depression of the vagal effects and in 11 experiments the latter were not significantly modified. Nine experiments were conducted on intact cats. Much more regular results were obtained in this series, compared with the isolated heart. In all the animals, stimulation of the sympathetic cardiac nerves which did not by themselves produce changes in cardiac rate (sub-threshold), induced, however, marked increases of submaximal bradycardic effects of the vagus. Similar results were obtained with threshold stimulation of the sympathetic. It seems interesting to point out that in the intact cat the cardiac response to stimulation of the sympathetic nerves is very minimal and rare. Usually only negligible effects were observed even with supramaximal stimulation. In the isolated heart, on the contrary,

the effects of the sympathetic nerves on cardiac activity are very manifest

Effect of pH on the three waves of the protein polarogram *G J Millar* (introduced by L B JAKUES) *Dept of Physiology, Univ of Saskatchewan, Saskatoon, Sask, Canada* Protein added to an ammonia buffer containing cobalt yields a polarogram exhibiting 3 waves (Jurka, *Collection Czech Chem Commun* 11 216, 1939, Millar, *Proc Can Physiol Soc* 1947) When the pH of the medium is altered, the magnitudes of the first two waves are either unaffected or are decreased as the pH falls, while that of the third ('prenatrium') wave is enhanced The following modification of Brdicka's reactions is proposed to account for the behaviour of the second wave $-SH + e \rightarrow -S^- + H$, $-S^- + H_3O^+ \rightleftharpoons -SH + H_2O$ The observed pH effect seems to depend on the concentration of cobalt- NH_3 complex The cobaltous complex dissociates easily as the pH is lowered In the presence of the stable cobaltic complex, the pH of the medium may be lowered to 3.5 with little effect on the height of the first two waves Hence, these waves are only indirectly dependent on pH

Experiments with acetylated proteins and some organic compounds suggest that the third wave depends on the free amino groups of the protein and possibly on histidine residues The following reactions are proposed $-NH_2 + e \rightarrow -NH_2^- + H$, $-NH_2^- + H_3O^+ \rightleftharpoons -NH_2 + H_2O$ When the pH is lowered a greater proportion of free amino groups are in the zwitterion form and the third wave is enhanced to a maximal value Its height is probably related to the protein dissociation curve

Effect of bacitracin on renal function JOHN H MILLER (by invitation), ROGER K McDONALD (by invitation) and NATHAN W SHOCK *Section on Cardiovascular Diseases and Gerontology, National Heart Institute, National Institutes of Health, Bethesda, Md, and the Baltimore City Hospitals, Baltimore, Md* The parenteral administration of bacitracin is productive of proteinuria in patients treated for various infections In the present study, serial renal function tests were performed on 12 subjects, free of infection, who received intramuscular injections of 1500 U of bacitracin per kilogram body weight on two successive days Proteinuria appeared in all individuals at 48-60 hours after the first injection, was maximal during the first 24-48 hours after its appearance (range of maximal 24-hour proteinuria was 0.7-9.7 gm), and persisted for an average of 10 days Microscopic examination of the urine revealed numerous tubular epithelial cells and an absence of red cells at the time of maximal proteinuria Tm_{PAH} was decreased at the time of maximal proteinuria from 15-85% (mean 39%) Tm_G was decreased from 20-76% (mean 52%) The maximal tubular excretory capacity for PAH and the maximal tubu-

lar reabsorptive capacity for glucose returned gradually over a period of 3 to 8 weeks to 88% or more of the baseline value in 10 to 12 subjects In the other 2 subjects, Tm_{PAH} was still depressed 25% at 8 weeks Inulin clearance was decreased from 2-75% (mean 32%), and the PAH clearance was depressed from 0-76% (mean 24%) during maximal proteinuria Both PAH and inulin clearances tended to return to baseline levels more rapidly than did the Tm values Unless the nephrotoxic principle contained in present preparations of bacitracin is an impurity which can be eliminated, these findings preclude the general use of this antibiotic by parenteral administration

Effects of growth hormone on the blood sugar and insulin sensitivity of the rat ANNE E MILMAN (by invitation) and JANE A RUSSELL *Dept of Physiological Chemistry, Yale Univ, New Haven, Conn* Observations were made concerning the effects of a highly purified preparation of growth hormone (prepared by Wilhelm, Fishman, and Russell) on the blood sugar and on the insulin sensitivity of fasted normal and diabetic rats When doses of 3 to 5 mg/100 gm were injected intraperitoneally into mature, normal or adrenalectomized male animals, a significant and prolonged depression of the blood sugar followed In alloxanized or partially depancreatized rats, on the other hand, these same preparations of growth hormone produced a marked rise in blood sugar This occurred in animals which were only mildly diabetic as well as those with more severe symptoms Normal animals pretreated with growth hormone 4 to 6 hours before were less sensitive to insulin Similarly, in diabetic animals, the duration of the blood sugar lowering effect of subcutaneously administered protamine-zinc-insulin was curtailed by injections of growth hormone (given 2-3 hours after the insulin) Growth hormone did not appear to alter the glucose tolerance of normal animals under our experimental conditions Bioassay of some of the growth hormone preparations showed traces of adrenotrophic hormone to be present, these amounts of ACTH were found to be to be insufficient to reproduce the effects observed in diabetic animals These results suggest that in the normal rat, the administration of growth hormone may provoke secretion of extra insulin In the animal lacking sufficient islet tissue, hyperglycemic or contra-insulin effects of the growth hormone are seen instead

Influence of intestinal motility on intestinal blood flow M SIDKY MOHAMED (by invitation) and JOHN W BEAN *Dept of Physiology, Univ of Michigan, Ann Arbor, Mich* The artery and vein to a loop of intestine of dogs anesthetized with pentothal were cannulated and the isolated loop set up in a perfusion apparatus Oxygenated heparinized dog blood was supplied to the tissue

under constant or pulsatile pressure. The venous outflow of blood was continuously recorded and the motility of the loop recorded from the lumen by tambour. On initiating the perfusion of quiescent gut the venous outflow was continuous but with the return of rhythmical contractions it became intermittent, increasing sharply during the contraction phase, decreasing or even momentarily stopping with relaxation. Since flow speeded up during the contraction phase the intermittence cannot be due simply to a cutting off of the arterial supply by occlusion of the vessels during the contraction, thus indicating the gut contraction causes an active propulsion of the blood from the tissue. Interruption of rhythmic contractions by periods of relative quiescence, at which time the arterial pressure should be most effective in increasing the flow, resulted in a decreased flow. The flow was also markedly augmented during the contraction phase of the longer tonic waves upon which the rhythmic contractions are superimposed but excessively strong tonic contractions, after initially increasing the flow, stopped the flow completely during period of high tonus presumably by passive vascular occlusion. On experimental occlusion of the venous outflow, venous pressure increased progressively and intermittently, coincident with successive rhythmical contraction phases. The experiments demonstrate the importance of intestinal motility in blood flow through the gut. Similar effects were with pulsatile and constant perfusion pressure.

Studies on vasotropic principles in blood (VEM and VDM) and renal hemodynamics in chronic heart failure. R. MOKOTOFF, D. J. W. ESCHER, I. S. EDELMAN, J. GROSSMAN and L. LEITER (all by invitation) and R. E. WESTON, B. W. ZWEIFACH and E. SHORR. *Medical Division, Montefiore Hospital, and the Dept. of Medicine, Cornell Univ. Medical College, the New York Hospital, New York City.* Since the increased renal arteriolar constriction in chronic congestive heart failure is probably not neurogenic, the possible role of VEM and VDM, newly described vasotropic principles, was investigated. Blood samples from the renal and hepatic veins, and the femoral artery or normal controls and of patients in chronic failure, were assayed for VEM and VDM by the rat meso-appendix test, in which the potentiation or inhibition of the arteriolar responsiveness to epinephrine is measured. Simultaneous renal hemodynamic and renal and hepatic oxygen extraction studies were performed. In all cases of congestive failure were both an increased filtration fraction and an increased oxygen extraction ratio were demonstrated, there were significant amounts of vasoexcitor principle (VEM) in the renal vein blood. In contrast, with one exception, almost no VEM was detected in the controls. The cardiacs had markedly reduced glomerular filtration rates and renal

blood flows with renal oxygen extraction increased to 14-29% as compared to 5-9% in the controls. Pronounced vasodepressor activity (VDM) was found in all hepatic vein samples of congestive failure patients. Only one control showed mild VDM. Although femoral arterial blood containing a mixture of VEM and VDM showed a slight predominance of the vasoexcitor principle in the majority of cardiacs, several did show a peripheral blood VDM predominance. This is important in view of the recent demonstration by Baez, Mazur and Shorr, that VDM has a profound antidiuretic effect. The relation of these principles to impaired renal hemodynamics in congestive failure will be discussed.

Method for the determination of heparin in blood. F. C. MONKHOUSE (by invitation), MARY STEWART (by invitation) and L. B. JAKES. *Dept. of Physiology, Univ. of Saskatchewan, Saskatoon, Sask., Canada.* A method for the determination of heparin in blood has been developed. It is applicable to the estimation of raised quantities of heparin in blood, as after intravenous injection, or anaphylactic shock. Blood is received into citrate and the heparin precipitated from the plasma with 7% octylamine hydrochloride. The precipitate is hydrolysed with 0.1N NaOH and the octylamine removed with ether. The heparin is then precipitated with 5% brucine phosphate at pH 6.0, and the brucine-heparin is washed with alcohol and ether and dried. The heparin present is assayed for its metachromatic activity with Azure-A using the method of Jakes, Mitford and Ricker (*Rev. Can. Biol.* 6: 740, 1947) or for antithrombin activity. Using the metachromatic method of assay, recoveries of 80-90% were obtained for heparin added to blood in concentrations of 0.2 to 3.6 mg/100 ml, while complete recovery of heparin was obtained from plasma. Normal human blood without added heparin gave a value equivalent to 0.009 mg % of heparin by this method. Owing to the extremely small amounts of heparin thus found in normal blood, certain modifications of the method are indicated in applying it to the estimation of normal blood heparin.

Further studies on the stimulating effects of light on sexual activity of the female opossum during the nonbreeding season. CHARLES F. MORGAN. *Dept. of Physiology and Biophysics, Georgetown Univ. School of Medicine, Washington, D. C.* Opossums were subjected to radiant energy from incandescent lamps, some with and some without monochromatic filters. The filters used were 'black' infra-red ($\lambda 8500$), red ($\lambda 6400$) and green ($\lambda 5460$). The radiant energy was determined by means of a chromel-constantan thermopile connected to a sensitive Rubicon galvanometer. Increase in the size and weight of the reproductive tract appeared directly proportional to the amount

of radiant energy received through lamps with and without filters. Thus radiant energy changes show greater effect than changes in wave lengths.

One group of opossums was exposed to a total amount of unfiltered radiant energy given 10 hours per day and compared with another group of opossums given the same total amount of radiant energy extending 20 hours per day with both groups receiving the treatment the same number of days. The sizes and weights of the reproductive tracts in both groups were similar. The degree of stimulation was the same as above when the animals received an equal amount of radiant energy from flashing lights given over a 20-hour daily period. Direct observations of the ovaries at laparotomy revealed ovulations in some animals receiving the stimulating effects of infra-red radiations. Ovulations have not been obtained in animals injected with varying amounts of gonadotropic hormones.

Sudden increases of radiant energy to a greater constant daily amount resulted in stimulation as great as that obtained in experiments previously reported (Morgan, Chas. F. *Federation Proc.* 6:359, 1947) in which incandescent light was increased by small increments each day such as occurs in nature.

Effect of spinal cord transection on the ventilatory response to exercise. DONALD P. MORGAN (by invitation) and FRED S. GRODINS, *Dept. of Physiology, Northwestern Univ. Medical School, Chicago, Ill.* The ventilatory response to electrically induced exercise of the hind limbs in barbitalized dogs was studied before and after section of the spinal cord at T₁₀. Respiratory rate, minute volume and oxygen consumption were determined at rest and during a steady state of exercise. Percutaneous electrical stimulation with 60-cycle AC modulated at 100/min. was used to produce oxygen consumptions up to seven times the resting value. A linear relationship was found between ventilation and O₂ consumption in 56 tests on 11 intact dogs. The regression equation was $Y = 0.56 + 0.031X$, where Y is ventilation in l/min., BPTS, and X is oxygen consumption in cc/min., STPD. The correlation coefficient was 0.97. A linear relationship was also found in 50 tests on 11 dogs after cord section. The regression equation was $Y = 2.31 + 0.027X$ and r was 0.78. Covariance analysis showed no significant difference between the regression coefficients, but a significantly higher adjusted mean ventilation in the sectioned animals. The latter was most apparent in the considerably higher resting ventilation after section. Respiratory patterns were different in the two groups, the tidal volume being less and the rate correspondingly greater at a given total ventilation in the sectioned animals.

Activity of single units in the cerebellar cortex. G. MORUZZI (by invitation), JOHN M. BROOKHART

and R. S. SNIDER, *From the Depts. of Anatomy and Physiology, Northwestern Univ. Medical School, Chicago, Ill.* Spike potentials have been recorded from single units having somas located in the cerebellar cortex. Glass micropipette electrodes having tip diameters of 5 to 20 microns have been used for unipolar recordings in unanesthetized decerebrate cats. The recorded spikes have the following characteristics: 1) duration of approximately 1 msec., 2) amplitudes reaching 250 microvolts, about 3 times the amplitude of the largest spontaneous cerebellar waves, 3) unbroken contour with rising phase shorter than falling phase. The unitary origin is indicated by 1) constancy of amplitude and contour, 2) possibility of identifying multiple units in the same record and 3) parallel modulation of amplitude of two units by slight cerebellar movements. Modification of spike frequency by local application of strychnine gives evidence of cortical localization of soma.

Spike activity falls into three classes: 1) injury, 2) normal spontaneous, and 3) convulsive. Injury discharges are characterized by normal spike contour, by frequencies higher than 100/sec. and by durations usually less than one minute. Normal spontaneous spikes have been recorded at frequencies from 25 to 150/sec. for many minutes; they usually occur in outbursts of variable duration. Occasionally, spike discharges have been evoked or inhibited by sensory stimulation. Convulsive outbursts of spikes have been produced by local strychninization of the cerebellar cortex. After an initial increase in frequency, resulting from strychnine, characteristic outbursts of convulsive activity occur, starting at frequencies above 200/sec., increasing to terminal frequencies up to 500/sec., and terminating abruptly.

Influence of bulbo-reticular stimulation upon electrical activity of cerebral cortex. G. MORUZZI (by invitation) and H. W. MAGOUN, *Dept. of Anatomy, Northwestern Univ. Medical School, Chicago, Ill.* The effect of stimulating the suppressor bulbar reticular formation upon cortical electrical activity has been investigated in cats under chloralose anesthesia. The high voltage, 5/sec. waves, characteristically pronounced in the sensori-motor area with this anesthesia, were abolished during such bulbar stimulation, while lower voltage, faster, background activity continued. This effect was most complete in the ipsilateral sensori-motor cortex, but was observed also in the visual area and contralaterally. It was prevented by section of the midbrain tegmentum, but not by section of the tectum or both bases pedunculi. It remained after complete paralysis with curare, and was not reproduced by antidromic stimulation of the bulbar pyramid. This effect was obtained with stimuli to the reticular formation of 300/sec. and 2-3 V. with individual shocks of 1

heparinized blood, usually have a moderately increased clotting time, and only rarely is it incoagulable. The blood is unusually dark and in most instances gelation precedes coagulation. Normal color, 'normal clot', normal or nearly normal clotting time and a decrease to or toward normal of the amount of titrating protamine are produced by administration of toluidine blue or protamine sulfate. Strikingly dissimilar, however, are the protamine titration changes relative to the clotting time. Only 0.75 mg/kg body weight of intravenous heparin is required to make the blood of a normal dog incoagulable (15 minutes after injection). The protamine requirement is increased when 1.0 mg/kg of body weight or more is given, and 3-5 mg must be injected to produce the changes similar to those seen in the patients and dogs.

Thalamic representation of tactile sensibility in the Macaque monkey. VERNON MOUNTCASTLE and ELWOOD HENNEMAN (introduced by PHILIP BARD). *Dept. of Physiology, Johns Hopkins Univ., School of Medicine, Baltimore, Md.* The thalamic terminations of afferent systems conveying cutaneous tactile sensation have been mapped by an application of the evoked potential technique. The responsive area is contained within the nuclei ventralis posterolateralis and posteromedialis. No responses were recorded from lateral, medial or anterior nuclear groups. The contralateral body surface is represented in nucleus ventralis posterolateralis in dermatome sequence, the caudal segments being most lateral, followed by lumbar, thoracic, and cervical segments in successively more medial positions. Those portions of the body most heavily innervated by sensory neurons, the apices of the limbs, receive greatest volume representation in the thalamus. The enlargement of the thalamic zone for the lower cervical segments (hand) has separated the zone for the upper cervical segments (head and neck) from that for the trigeminal nerve.

The face and mouth are represented in nucleus ventralis posteromedialis. The pattern suggests a para-oral, segmental representation of the trigeminal fields, with lips and mouth placed medially. The intra-oral structures are represented bilaterally. In the most medial position is a small area for ipsilateral face. Responses to tactile stimulation of ipsilateral body and face have been recorded from points in and near the external medullary lamina, but a zone of thalamic transfer of impulses destined for the second somatic area of the cerebral cortex has not been located definitely.

Studies on the renal secretion of potassium in the dog. GILBERT H. MUDGE (by invitation), JAMES G. FOULKS (by invitation), ADELBERT AMES, III (by invitation), and ALFRED GILMAN. *Dept. of Pharmacology, College of Physicians and Surgeons, Columbia Univ., New York City.* Potassium (K) clearances (CK) greater than simultaneous creati-

nine or thiosulfate clearances (CF) are considered evidence that a part of urinary K results from renal tubular secretion. CK/CF ratios over unity are most readily obtained by the intravenous infusion of K salts, a procedure which yields average ratios of approximately 1.3, occasionally rising higher. The intravenous infusion of hypertonic solutions of urea and sodium chloride also promotes the excretion of K. During water diuresis CK/CF remains low. A variety of drugs known to affect renal function has been studied for their effects on K excretion. Mercurial diuretics were the only agents to possess a significant action. These sharply diminished the excretion of K during K administration and during states of hypertonicity, and slightly elevated CK/CF during water diuresis. The effects of mercury were rapidly reversed by BAL. Although it is not possible from the data thus far obtained to determine the exact contribution of the secretory process to the excretion of K, the available results may be explained by the hypothesis that tubular secretion is a response to hypertonicity or to elevated cellular K following K infusion and that the action of Hg^{++} is to depress this process. If this hypothesis is correct it follows that a major portion of excreted K results from secretion.

Polarographically determined protein index. Nature of the cobalt-catalyzed reaction of cysteine. OTTO H. MÜLLER. *Dept. of Physiology, Syracuse Univ. College of Medicine, Syracuse, N. Y.* In continuation of the studies of the 'protein index' (Müller and Davis, *Arch. Biochem.* 15: 30, 1947) it became necessary to know more about the nature of the electrode reaction which produces the catalytic wave of sulfhydryl groups in the presence of a buffered cobalt solution. Consequently cysteine was polarographed over a large range of concentrations in solutions containing 0.1 N NH_4OH , 0.1 N NH_4Cl and several different concentrations of $CoCl_2$. The catalytic wave was observed at cysteine concentrations as low as 2×10^{-7} M. Its height is proportional to the surface area of the mercury drop but it is not a linear function of the Co^{++} concentration. It plotted against the logarithm of the cysteine concentration, it yields an S-shaped curve, typical of catalytic reactions. At higher cysteine concentrations a new wave was discovered which just precedes the above catalytic wave, it usually overlaps with it at lower concentrations. The height of this new wave is proportional to the concentration of Co^{++} ions and to the sixth root of the drop time, which suggests a type of diffusion current, its relationship to the cysteine concentration is more complex. From this and other evidence it is concluded that the first mentioned wave is produced by the catalytic action of the cobalt amalgam which is formed at the dropping mercury electrode, whereas the new wave is produced by the action of a

number of factors upon which these differences depend, *in vitro* as well as *in vivo*. Even working with the virtually pure enzyme solution, the reaction rate depends at least on three variables—enzyme, inhibitor and substrate. Variations of the concentration of each of these three components affect markedly the inhibitory effect. Considerable differences are observed between reversible and irreversible inhibitors, but even compounds belonging to the same group may show entirely different behavior. A few examples will be discussed. Still more factors determine the effect *in vivo*. Of special importance is the structural barrier surrounding the axons. Lipid insoluble compounds act only upon the synapse. But between lipid soluble inhibitors exist interesting differences. Some physiological implications of these observations will be discussed.

The spread of excitation and the order of depolarization in the human heart. L. H. NAHUM and H. M. CHERNOFF (by invitation). *Laby of Physiology, Yale Univ. School of Medicine, New Haven, Conn.* To determine the nature of VR, VL and VF in man it is necessary to know the 'proximal' and 'distal' zones of each lead. This information was obtained by projecting solid cones from the position of each electrode upon the heart, the area subtended being considered the proximal zone. The position of the heart was taken from X-ray views obtained at various angles. A geographic map was then constructed, showing the overlapping of the proximal and distal zones. By analyzing the positions of the beams from moment to moment in the simultaneously recorded QRS complex of each lead, the order of arrival of the excitation process at the various segments of the heart was determined.

The region first to receive the excitation process was lower anterior septum. Excitation then spread rapidly to involve anterior and posterior right ventricle, then to left apex and left posterior ventricle. Excitation terminally involved a region of the right anterior ventricle (conus area). This order of spread corresponds to that already described in the dog and agrees with observations made upon the exposed human heart. The order of repolarization was determined from analyzing the position of the ST-segment and direction of the T-wave in unipolar extremity leads and in simultaneously recorded CV1 to CV6. It was found that the apical and diaphragmatic region of the heart is the site of fastest repolarization.

Nitrogenous excretion in *Colpidium campylum*. ROY and M. NARDONE (introduced by CHARLES G. WILBER). *Biological Laby, Fordham Univ., New York City*. Wilber and Scamen (*Biol. Bull.*, 93: 214, 1947) found that *Colpidium campylum* can synthesize fat from protein. The following investigation was undertaken in an attempt to ascertain the nature of nitrogenous excretion in *Colpidium*

campylum when grown on a protein medium (proteose-peptone). Quantitative analyses for ammonia, in pure, sterile cultures of colpidia, were made using the permutit method (*J. Biol. Chem.* 29: 329, 1917). No ammonia was found 24 hours after inoculation. A straight line increase in ammonia with time was obtained from the 2nd day after inoculation to the 14th day after inoculation. The mean population reached a maximum of approximately 68,000 organisms per ml of culture on the 9th day after inoculation. The population then decreased gradually to approximately 41,000 colpidia per ml on the 14th day after inoculation. The results shown below are mean values of 5 analyses each day.

NO. DAYS AFTER INOCULATION	POP. /ML	AMMONIA N
		γ /ml
1	5,500	0.00
2	17,025	0.71
3	18,450	1.43
4	46,620	4.28
5	52,500	6.09
6	61,200	7.85
7	63,855	9.10
8	62,550	8.20
9	67,965	10.00
10	50,110	13.85
11	53,100	13.20
12	43,240	16.40
13	40,350	18.05
14	40,890	17.90

Using a qualitative spot test (Feigl), no uric acid was detected throughout the experiment. Urea, however, was produced during the logarithmic phase of growth.

Effects of eserine and pilocarpine on the parasympathetically denervated iris of the cat. ENID A. NEIDLE (introduced by WALTER S. ROOT). *Dept. of Physiology, College of Physicians and Surgeons, Columbia Univ., New York City*. According to Anderson (1905) the iris of the cat which, immediately after removal of the ciliary ganglion, responds to eserine soon ceases to do so and remains unresponsive. There is then a gradual return of the eserine response in the denervated sphincter. This has been taken as evidence for nerve regeneration. In 5 cats in which one ciliary ganglion had been removed and which showed a return of responsiveness to eserine, the oculomotor nerve was sectioned intracranially. Ten days later, the response of the sphincter was tested by instilling 0.4 mg of eserine salicylate into the conjunctival sac. In every instance there was complete or partial loss of response. This supports the belief of Anderson (1905) that preganglionic cholinergic fibers can replace postganglionic cholinergic fibers. Instillation of 0.04 mg of pilocarpine nitrate in the conjunctival

sac produces marked constriction of the ganglionectomized iris but has no effect on the normal iris. The sensitivity of the denervated iris to pilocarpine diminishes slightly but significantly with time after operation. Section of the oculomotor nerve, some time after removal of the ciliary ganglion, is followed by a complete or partial restoration of sensitivity to topically applied pilocarpine. It is suggested that the decrease in sensitivity to pilocarpine may be related to the occurrence of regeneration to the denervated sphincter of the iris.

Effect of hydration on the survival of fasting rats. DOROTHY NELSON (introduced by A. C. Ivr) *Dept. of Clinical Science, Univ. of Illinois College of Medicine, Chicago, Ill.* Rats deprived of food dehydrate themselves even in the presence of adequate water. There is considerable evidence in support of the hypothesis that rats ingest any available material that is of benefit to them. In sharp disagreement, a growing literature indicates that in many situations rats fail to make advantageous selection of foods. Is the voluntary dehydration of the fasting rat protective or detrimental? To clarify this point we have compared the survival of several groups of mature females. With no food or water the rats lived about 11 days. The injection of 7.5 cc of 0.6% NaCl solution every 12 hours prolonged life about 3 days, a significant increase. Similar injection of 0.9% NaCl solution had no effect on survival, though less weight was lost than in the control groups. It appears from this, that the rat's refusal to drink in the absence of food, does not represent an attempt to maintain an optimal water balance, but probably results from a break down of the mechanisms for fluid adjustment.

Effect of elemental iodine and iodocasein in hypothyroidism induced by methyl thiouracil. WARREN O. NELSON and EILEEN B. HINES (by invitation) *Dept. of Anatomy, State Univ. of Iowa, Iowa City, Iowa.* Young male and female rats weighing 40-50 gm. were placed on a stock diet containing 0.2% methyl thiouracil. After 30 days the animals in each experiment were divided into 3 groups. One continued on the methyl thiouracil diet, a second received the same diet with 0.033% iodocasein, while the third received the same diet, but in addition received 4.0 or 6.0 mg. elemental iodine daily by subcutaneous injection. The second phase of the experiment was continued for 30 or 60 days. Control animals received the regular stock diet throughout the experimental period. For males in the longer experiments the averages for final body weight and total length were respectively: normal controls, 375 gm., 41 cm.; methyl thiouracil only, 95 gm., 28.5 cm.; methyl thiouracil and iodine, 175 gm., 33 cm.; methyl thiouracil and iodocasein, 252 gm., 38 cm. The animals which received methyl thiouracil only showed markedly reduced testicular function, both gametogenic and endocrine. The adrenals, thymus, spleen, liver, heart, submaxillary

glands and kidneys all showed marked reduction in weight as compared to the controls. However, all of these except the thymus corresponded to the reduction in body weight. Iodine induced definite improvement in testicular function and in organ weights, but was less efficacious than iodocasein. Females of the several groups showed the same trends for body weight, body length, ovarian function and organ weights. Estrous cycles were markedly improved by both iodine and iodocasein. Determinations of plasma protein-bound iodine revealed high levels for animals which received iodine or iodocasein.

Transmission spectra of the human ear (pinna and lobe) at arterial occlusive pressures. J. F. NEVILLE, JR., J. O. ELAM, K. SUGIOKA, and A. ROOS (introduced by H. L. WHITE) *Laby of Applied Thoracic Physiology (Surgery) and Dept. of Physiology, Washington Univ. School of Medicine, St. Louis, Mo.* Factors related to the accuracy of the oximeter have been investigated by spectrophotometry of the intact human ear. Instrumentation consisted of a Littrow type monochromator (resolution of 80 Å), S-4 and S-1 response phototubes, AC amplifier, and continuous ink recorder. The monochromatic beam was directed via quartz to the ear of the recumbent subject. The recording spectrophotometer automatically scanned the spectrum between 4000 and 11000 Å. Ear tissue was compressed with translucent rubber diaphragm by pneumatic inflation to 200 mm. Hg. Spectra were calculated as percentage absolute transmission ($\%T = \frac{I_t}{I_0} \times 100$, where I_0 = phototube response).

Data obtained in 10 male and 2 female normal white subjects indicated: 1) the bloodless pinna and lobe transmissions were zero at wavelengths shorter than 5100 Å, 2) the maximal transmissions of the bloodless pinnae were uniformly at 8800 Å, 3) the maximal transmissions of the bloodless lobes covered a broad spectral band from 6500 to 10000 Å, 4) the absolute transmissions of the bloodless pinnae averaged 15% between 6000 and 10000 Å while comparable values for the lobes averaged 26%, 5) the spectra of the bloodless pinnae indicated marked light scattering between 8800 and 5100 Å (decreasing transmission with decreasing wavelength) while this effect was much less evident in the lobe spectra, and 6) the absorption band of water between 8500 and 9800 Å was evident particularly in the pinna spectra. The lobe of the ear appears to offer optical advantages superior to the pinna as the site for oximetry.

Effect of diets containing certain tissues on liver regeneration in the rat. E. NEWMAN (by invitation) and A. C. Ivr *Dept. of Clinical Science, Univ. of Illinois College of Medicine, Chicago, Ill.* Previous studies in this laboratory had shown that liver regeneration in partially hepatectomized rats was more rapid in rats fed whole cooked liver or

dried whole liver than in those fed casein or beef heart. The growth promoting factor was shown not to be in crude liver extracts. In order further to analyze this effect diets containing certain organs other than liver were fed to partially hepatectomized rats. The organs studied included spleen, kidney and duodenum. None of these organs were equal to liver in promoting liver regeneration. Studies were also made using nucleic acid or uracil supplements to a standard synthetic diet. Nucleic acid (derived from yeast) was as effective as whole liver in promoting liver regeneration. Uracil had no effect.

A 'vertical tube' method for the study of pressure-flow relations in vascular beds. J. NICHOL (by invitation), F. GIRLING (by invitation) and A. C. BURTON, *Dept. of Biophysics, Univ. of Western Ontario, London, Canada*. In the perfused preparation, as the isolated rabbit's ear, a vertical small-bore glass tube is connected (as a 'T') to the arterial cannula through which perfusion is made, while in the 'intact' preparation, as the hind-limb it is connected to a T-cannula inserted into the artery. In the latter case, the fluid in the vertical tube is separated from the flowing blood by a slack rubber membrane. The liquid in the tube stands at a height giving the pressure in the artery at that point. The artery, or tube from the perfusion bottle, is then clamped on the high pressure side of the T. The circulation in the preparation then proceeds, maintained by 'bleeding' from the vertical tube, at a steadily diminishing driving pressure. The height of the vertical column is plotted against time, giving an exponential-like curve. Tangents drawn to the curve at specific pressures give the flow through the vascular bed at any pressure. It can be shown that the length of the sub-tangent is a direct measure of the resistance to flow. Complete pressure-flow relations are thus obtained. These agree with those obtained by altering the pressure head and measuring flow by a micro-flow meter, but the vertical tube method is much more convenient and very accurate at low pressures and flows, where theoretical interest is greatest.

Time course of failure of the visual pathway in rabbits during anoxia. WERNER K. NOELL and HERMAN I. CHINN (introduced by HARRY F. ADLER), *USAF School of Aviation Medicine, Randolph Field, Texas*. In order to determine the factors responsible for the sequence of anoxic failure, potentials resulting from illumination of the eye and from electrical stimulation of the optic nerve were recorded from different parts of the visual pathway. Amplitude and timing of these responses were measured during nitrogen breathing. The curves for the decline in responsiveness thus obtained reveal, as one factor, the effectiveness of a decreased excitability on differently organized neuronal systems. Complete irresponsiveness at the surface of the striate area to either

photic or electrical stimuli was reached after 88 seconds of nitrogen breathing (blood was oxygen free within 30 to 45 seconds). The immediate post-synaptic potentials from the geniculate disappeared after 113 seconds. Potentials of the optic tract to strong photic stimuli became undetectable after 256 seconds and to maximal electrical stimuli after 293 seconds. One portion of the b-wave of the electroretinogram decreased simultaneously with the optic tract potentials, 25 minutes were required until all positive components of the electroretinogram had disappeared. A small negative electroretinogram persisted for many hours. All figures represent mean values. Intravenous administration of iodoacetate quickly abolished retinal excitability during air breathing. Neither the anoxic decline of cortical responsiveness nor the failure of the optic nerve to direct stimulation was hastened. Lethal doses of fluoride did not specifically affect retinal excitability immediately after injection. However, during subsequent anoxia all positivity of the electroretinogram disappeared more rapidly, while the survival times of cortex and optic nerve were not decreased.

Incorporation of glycine in the tissues of acutely starved rats. T. R. NOONAN, K. I. ALTMAN, G. W. CASARETT, and K. SALOMON (introduced by WILLIAM F. BALE), *Dept. of Radiation Biology, School of Medicine and Dentistry, Univ. of Rochester, Rochester, N. Y.* The effects of acute starvation upon the incorporation in tissues of glycine, labelled in its alpha-carbon atom with C_{14} , have been studied in the rat. One microcurie of labelled glycine (specific activity 1.83 $\mu\text{C}/\text{mg}$) was injected intravenously into normal rats and into rats which had been starved for 5 to 7 days, 24 hours after injection, the animals were killed and tissue samples secured for analysis of C_{14} content. Samples from the liver, gastrointestinal tract, kidneys, testes, and brain of animals starved for 5 or 7 days showed a markedly higher radioactivity per gram than corresponding samples from control rats. On a unit weight basis, the muscles of starved animals showed lower C_{14} concentration than control animals, this effect being more marked after 7 days of starvation. When calculated on the basis of percent of injected C_{14} activity found per total organ, the starved animals showed a pattern of decreased incorporation in muscular tissue with an unchanged or even increased incorporation in visceral tissues.

Time-dose study of biochemical responses of rats to x-radiation. N. NORTH (by invitation) and L. F. NIMS, *Brookhaven National Lab., Upton, L. I., N. Y.* A time-dose study of biochemical responses of the adrenal-pituitary system in fasted rats following whole body x-radiation indicates a pattern of changes comparable to that following other stresses. Male albino rats were subjected to radiation doses of 500 to 2000 r at a rate of 50 r per minute and sacrificed at periods of time ranging

from 3 to 48 hours following exposure. Analyses of tissue constituents show an immediate and progressive increase in liver glycogen and no change in testis glycogen. There is a simultaneous decrease in the adrenal and liver cholesterol but little change in the testis cholesterol and a late increase in the plasma cholesterol. The adrenals also show an initial decrease in ascorbic acid content with a subsequent return to normal, while little variation from the unirradiated controls is seen in pituitary, liver or testis ascorbic acid. There are no evident effects of radiation on total body, adrenal or pituitary weights in fasted animals.

Acclimatization to histotoxic anoxia DAVID W. NORTHUP and ROSS BELL, JR. (by invitation) *Dept of Physiology, School of Medicine, West Virginia Univ, Morgantown, W Va*. In order to determine whether acclimatization to histotoxic anoxia occurs in a manner similar to that seen during anoxic anoxia, the red cell count, reticulocyte count, and hemoglobin concentration of the blood of three rabbits were followed during the administration of potassium cyanide. Determinations were made daily during an 11-day control period and then KCN was administered subcutaneously in doses ranging from 1.0 to 3.1 mg/kg/day, the dose being increased as the animals developed tolerance (Sufficient cyanide was given to produce distress). The average red cell count of the 3 rabbits rose from 4.97 million during the control period to 5.37 million during the period of cyanide administration, significant at the 0.1% level, the hemoglobin from 10.95 gm to 11.92 gm significant at the 0.1% level, the reticulocyte count from 1.0% to 2.3%, significant at the 0.1% level. The results indicate that the rabbit responds to histotoxic anoxia by increased activity of the bone marrow.

Inside the cell Part I Enzymes in intracellular chemistry (Motion picture) ALEX B. NOVIKOFF (introduced by F. J. SICHEL) *Dept of Pathology, Univ of Vermont College of Medicine, Burlington, Vt*. Produced by the United States Army Medical Illustration Service, under the supervision of the Surgeon General, this film is intended for teaching professional medical personnel of the Services and civilian medical and university students. It suggests the importance to medical practice of a knowledge of enzymes and cell metabolism. After briefly sketching the historical development of our knowledge of enzymes, the film deals in detail with the known steps of glucose metabolism, including glycolysis, the tricarboxylic acid cycle, hydrogen transport via the cytochrome system, and the phosphate or energy cycle. It suggests points of contact of the metabolism of carbohydrates and other foodstuffs, and it indicates the relation of vitamins and minerals to enzyme structure. Most of the film is in color animation. There are also live action demonstrations of several sections, photographed in the laboratories of the individuals mentioned.

J. B. Sumner shows the essential steps in the crystallization of urease. Otto Meyerhof demonstrates the need of DPN and ATP in glycolysis. Severo Ochoa shows the enzymatic decarboxylation of oxalosuccinic acid and the oxidation of isocitric acid. Carl F. Cori and Gerty Cori demonstrate the *in vitro* synthesis of glycogen and starch. Carl F. Cori and M. E. Krahli show the effect of insulin and adrenal hormone on the uptake of glucose by diaphragm muscle. Van R. Potter demonstrates the low succinic dehydrogenase activity of tumor homogenates as compared with those of normal organs.

Response to intravenous injection of small quantities of insulin JOHN A. NUETZEL (by invitation) and NORMAN S. OLSEN *Dept of Internal Medicine and the Oscar Johnson Inst, Washington Univ School of Medicine and Barnes Hospital, St Louis, Mo*. A modified intravenous insulin tolerance test, using $\frac{1}{10}$ unit of insulin/kg body weight, was performed in a series of normal, hypertensive, and other patients. Blood sugar levels were determined at 0, 15, 30 and 60 minutes after intravenous injection, by the method of Nelson. The data were analyzed on the basis of the percentage fall from the fasting level. Certain clinical groups were resistant to the action of intravenously administered insulin in that they showed significantly less fall in 15 and 30 minutes than did the normal group. These groups consisted of patients with malignant hypertension, with hypertension and severe complications (such as stroke and heart failure), with advanced neoplastic diseases, liver diseases, collagen diseases, and psychosomatic disorders. Resistance was also found, as expected, in active infections and certain endocrine disorders. Hypertensive patients having an endocrine or neurogenic basis and not in a malignant phase were not resistant.

Blood pressure after nephrectomy ERIC OGDEN, ELEANORE TRIPP (by invitation) and GEORGE CONSTANT (by invitation) *Dept of Physiology, Univ of Texas Medical Branch, Galveston, Texas*. Grollman reported occasional elevations of blood pressure in rats and dogs after unilateral nephrectomy. In the present group of 5 well-trained dogs series of measurements were made before and 5 months after removal of the left kidney. The table indicates the average values for the individual dogs.

DOG	BEFORE NEPHRECTOMY		AFTER NEPHRECTOMY	
	Syst./Diast.	P rate	Syst./Diast.	P rate
1	165/80	115	194/105	100
2	168/83	90	188/107	101
3	133/60	103	166/80	86
4	189/59	95	167/95	95
5	165/81	150	171/97	91

Blood pressure was computed from records made without anesthesia by puncture of the femoral artery with the needle connected to a glass spoon manometer with optical recording, the pulse counts were computed from the same records. It is believed that the lowered pulse rates after nephrectomy are indications that the dogs were better trained. The elevation of both systolic and diastolic pressures in each animal considered separately was statistically examined and found unlikely to be due to chance. That such an occurrence would appear in 5 consecutive animals is overwhelmingly likely to be due to something other than chance even though the changes are small and only two of the dogs showed blood pressure levels which might be considered mildly hypertensive.

Treatment and prophylaxis of experimental hypertension with amines. E. A. OHLER (by invitation), G. E. WAKERLIN and G. A. ALLES (by invitation) *Dept of Physiology, Univ of Illinois College of Medicine, Chicago, Ill.* Paredrine HBr has been previously reported (*Federation Proc* 7 87, 1948) to be effective therapeutically in experimental renal hypertension. Since our last report 3 neurogenic (debuffered) hypertensive dogs have been treated with 4 mg/kg of Paredrine orally for periods of 3 to 6 months. Two neurogenic dogs showed excellent reductions in blood pressure, one, a good response. Of 5 dogs treated prophylactically with 4 mg/kg of Paredrine orally daily for periods of 3 to 6 months, all showed a rise in blood pressure following bilateral renal artery constriction. Two animals exhibited rises of 55 mm Hg, one dog developed malignant hypertension and died, and the remaining 2 showed rises of 20 mm Hg or more. The following compounds, closely related chemically to Paredrine, have failed thus far to exhibit any antihypertensive activity: 2-amino-1-cyclohexylpropane, levoamphetamine, ephedrine, hydroxy-tyramine, hydroxy-paredrine, and dl-1-parahydroxyphenyl-3-aminobutane. Tyramine in a dosage of 2 mg/kg IM daily produced a modest fall in the blood pressure of 1 renal hypertensive animal. Of 3 renal hypertensive dogs treated with Paredrinol (dl-1-parahydroxyphenyl-2-methyl-aminopropane) in a 4 mg/kg dose orally only one showed a reduction in blood pressure. Tuamine (2-aminoheptane) at a dosage level of 4 mg/kg IM has proved ineffective in 2 hypertensive animals.

Diuretic response of normal and edematous dogs to intravenous administration of succinate and fumarate sodium salts. ELIZABETH O'LEARY (by invitation) and SAMUEL A. CORSON *Dept of Physiology, School of Medicine, Howard Univ, Washington, D. C.* Hypertonic solutions (1.4M) of disodium succinate and fumarate salts were administered intravenously to trained unanesthetized dogs by means of a constant infusion pump

at the rate of 2.5 ml/min, injecting a total dose of 10 ml/kg of body weight. Such an infusion increased the rate of urine flow from an average control value of 0.4 ml/min to an average value of 4.2 ml/min for a period of about 300 minutes. The net quantity of fluid lost by the animals as a result of the administration of these salts (after subtracting the quantity of fluid injected and the quantity of urine that would normally have been excreted) was on the average 67 ml/kg body weight. Administration of these salts to dogs with experimental hypoproteinemic edema (produced by a combination of massive plasmaphereses and a low protein diet) led to a net average increase in urine output of 76 ml/kg body weight. We must therefore conclude that the diuretic responses of dogs with hypoproteinemic edema to the intravenous injection of succinate and fumarate salts are of the same order of magnitude as (or possibly greater than) those of normal animals.

Graphic measurement of arterial pressure in the intact rat. F. OLMSTEAD and O. GLASSER (introduced by A. C. CORCORAN) *Research Division of the Cleveland Clinic Foundation and the Bunts Institute, Cleveland, Ohio.* The method previously described (*Federation Proc* 7 88, 1948) for measurement of systolic pressure from the foot pulse of rats had been modified for greater accuracy and convenience. A light weight pickup has been developed which consists of 2 miniature coils separated by a small layer of sponge rubber. This device is readily attached to the front or hind foot of the rat and substitutes for the strain gauge previously employed. A frequency discrimination circuit is used to transfer the pulse into electrical change. For greater compactness and accuracy in recording cuff pressure, a Selsyn generator and motor are used. The generator is driven by a large metal bellows. The motor is mounted in the Brush ink oscillograph and drives a recording pen. Seventy-five simultaneous optical recordings were made of carotid pressure by a Hamilton manometer and of foot systolic pressure as indicated from the foot pulse. The mean deviation of indicated pressure in the hind foot from that in the carotid artery was -5.4 mm Hg. Variation around this mean was ± 3.5 mm Hg. These measurements were made over a range of systolic pressure from 52 to 170 mm Hg.

Effect of intrapulmonic and intrathoracic pressure variations on left atrial pressure. D. F. OPDYKE and G. A. BRECHER (by invitation) *Dept of Physiology, Western Reserve Univ Medical School, Cleveland, Ohio.* Mechanical factors of extra-cardiac origin which exert pressure on the heart chambers become of great importance in determining pressure-flow gradients in the presence of intra-cardiac shunts. If these extraneous forces do not affect all cavities equally it is possible that their effect may be directly opposite to that

desirable for physiologic compensation. Experiments have been undertaken to assess the effects of two of these factors, intrapulmonic and intrathoracic pressure, on left atrial pressure, since the pressure variations in this heart chamber have been so little studied.

Positive pressure inflation of the lungs in an open chest dog results in an increase of both right and left atrial pressure with a decrease in aortic pressure. This effect is intensified by maintenance of the lungs in the inspiratory position for a few seconds. Right pressure increases considerably more than left. Ventral traction on the pericardium, lung roots, aorta, and other thoracic structures does not reproduce this effect. Experiments dealing with the effect of intrathoracic pressure changes and with the effects of positive pressure breathing on left atrial pressure in the closed chest dog are described and the results presented.

Diuretic effect of adrenal cortical hormones in mildly hydrated and dehydrated animals. C. M. OSBORN and W. J. EVERSOLE (introduced by ROBERT GAUNT) *Dept. of Zoology, Syracuse Univ., Syracuse, N. Y.* Experiments were made to determine the conditions under which the diuretic action of adrenal cortical hormones could be demonstrated in intact rats. In previous experiments with water given *ad lib.*, desoxycorticosterone acetate (DCA) caused a diabetes insipidus-like state (Selye and Bassett), this condition was intensified by addition of salt to the diet (Corey and Britton, Ragan *et al.* Richter). When large multiple doses of water were force-fed, both DCA and cortical extract enhanced markedly the diuretic rate and prevented water intoxication (Gaunt). The possibility exists that such effects are manifested only in the presence of high water loads induced either indirectly by salt retention or directly by water administration. Forty-eight fasted male rats were given a single hydrating dose of water by stomach tube (4 ml/100 cm² of body surface, average dose = 12 ml). One group received 5 mg DCA one-half hour before water was given, 90 minutes later they had excreted 11% more urine than controls, a result similar to that following chronic DCA treatment (Selye and Bassett). With same water dosage, another group received 4 ml of Upjohn's adrenal cortical extract (alcohol removed), force-fed as a portion of the water dose. These animals excreted 31% more urine than saline-treated controls. Forty-eight rats were deprived of food and water for 20 hours. Beginning at the 13th hour, part of the animals were given DCA at intervals until dosage totaled 4 mg and others received a total dosage of 4 ml of cortical extract. With such dehydration and acute treatment, DCA had no effect on urine volume, but the cortical extract doubled urine

output. It appears, therefore, that the diuretic action of DCA may be somewhat dependent on water load, while cortical extract enhances diuresis under all observed conditions of water balance.

Application of Gray's theory of respiratory control to the hyperpnea produced by 'passive' exercise. ARTHUR B. OTIS *Dept. of Physiology and Vital Economics, Univ. of Rochester School of Medicine and Dentistry, Rochester, N. Y.* Movements of the limbs produced by external forces cause an increase in the minute volume of ventilation as, has been observed by several previous investigators. Such movements, however, are not entirely passive but produce an increased oxygen consumption. Continuous measurements of the alveolar gas tensions make possible the estimation of the ventilatory stimulus due to the limb movements *per se* by application of Gray's multiple factor theory. Such calculations show that the stimulus from such movements is enough to produce a ventilation increment 100% to 150% of the resting ventilation.

Anemia producing properties of hexahomoserine and the antagonizing effect of lysine. EDOUARD PAGÉ and R. GINGRAS (by invitation) *Depts. of Nutrition and Biochemistry, Medical School, Laval Univ., Quebec, Canada.* Hexahomoserine (α -amino- ϵ -hydroxycaproic acid) produces anemia and inhibits growth in the rat. It also causes a considerable rise in blood plasma amino nitrogen. Simultaneous lysine supplementation prevents the anemia, improves partially the growth rate but has no effect on the plasma amino nitrogen. These observations were made on rats receiving either a complete basal ration or one containing no lysine. Amino-adipic acid, a biological derivative of lysine, antagonizes neither hexahomoserine, nor lysine. Liver concentrates and folic acid are ineffective in the prevention of the anemia caused by hexahomoserine.

Mechanisms of the vascular action of tetraethylammonium chloride. IRVINE H. PAGE, RALPH PRINCE (by invitation) and JOHN J. REINHARD, JR. (by invitation) *Research Division and Bunts Institute of the Cleveland Clinic Foundation, Cleveland, Ohio.* Acheson, Moe, Lyons and Hoobler introduced tetraethylammonium chloride as a means of blocking autonomic ganglionic transmission to measure autonomic activity. Although we were unable to show a significant difference in response to TEA after renal hypertension developed, individual responses were so variable that blockade of ganglionic transmission probably was not the only action of TEA. Ninety-four normal dogs showed widely variant responses. Occasional 'normal' animals showed a rise in blood pressure rather than the more usual short rise followed by a fall. On repeating the doses, the responses became progressively less depressor and,

finally, pressor Destruction of the spinal cord from C₆ caudad caused invariably a pressor response to every injection, and inactivation of the carotid sinus mechanism either did not change the response or somewhat augmented it In 2 patients with severe central nervous system lesions pressor responses were observed with the initial dose Bilateral nephrectomy done 2 days before testing usually accentuated the pressor component while bilateral adrenalectomy very moderately reduced it Hepatectomy greatly increased the depressor action TEA caused little or no rise in pressure after hepatectomy, hepatectomy-nephrectomy-adrenalectomy, or in animals with spinal cord destroyed, carotid sinus mechanism inactivated, kidneys and liver removed The pressor response was abolished by prior administration of Dibenamine and Priscol sufficient to reduce or abolish the action of arterenol and reverse adrenalin The response to TEA appears to be composed of 2 components one dependent on blockade of autonomic ganglionic transmission, the other, dependent probably on liberation of an arterenol-like substance

Observations on pulmonary lymph flow and edema ROBERT PAINE (by invitation), FRANK A HOWARD (by invitation), HARVEY R BUTCHER (by invitation) and JOHN R SMITH *Cardiovascular Division, Dept of Medicine, Washington Univ School of Medicine, St Louis, Mo* Lymph flow from the lungs of dogs has been studied Using Drinker's method, the pulmonary lymphatics were isolated, and intact, or open thorax preparations under positive pressure respiration, were made The lung lymph was measured by cannulation or by catching the fluid on weighed pledgets Obstruction of the pulmonary veins producing moderate elevation of venous tension and pulmonary congestion showed no effect on the rate of lymph flow However, maximal pulmonary venous congestion results in increased lung lymph (Drinker) The reduction of plasma proteins to 2.5 gm % or less by plasmaphoresis, and by the administration of Locke's solution, caused a marked increase in lung lymph flow Furthermore, when pulmonary lymphatic drainage was curtailed by obstruction of the superior vena cava, a rise in lung lymphatic pressure occurred as noted by direct manometry of the lymphatic system However pulmonary edema was not observed following any of these procedures When lymphatic outflow was obstructed, the critical diminution of plasma proteins produced gross pulmonary edema The effects of increased hydrostatic pressure and decreased osmotic pressure indicate the operation of Starling's hypothesis in the lung The curtailment of lymph outflow due to peripheral venous hypertension from heart failure, in conjunction with pulmonary congestion or

hypoproteinemia, may be important in the precipitation of pulmonary edema

Variability and reliability of cardiac index estimations with the high-frequency, undamped ballistocardiograph ROBERT M PAINE (by invitation) and NATHAN W SHOCK *Section on Cardiovascular Diseases and Gerontology, National Heart Inst, Bethesda, Maryland, and the Baltimore City Hospitals, Baltimore, Maryland* The ballistocardiograph used was horizontal, undamped, and had a natural frequency of 12.6 cycles/sec when loaded with 150 lbs The calibration was such that a force of 280 gm applied to the bed caused a displacement of 1 centimeter on the photographic paper record The largest and smallest complexes in each of 2 representative respiratory cycles of each tracing were selected independently by 2 observers and the average areas (mm-sec) under the I-waves and J-waves were inserted into Tanner's formula stroke volume in cc per minute = $\sqrt{21 + J\sqrt{C}}$ C represented the duration of a cardiac cycle in seconds Cardiac index (L/min/M²) was estimated in the basal state, after a standard meal, at hourly intervals throughout a day of ordinary activity, and at 5-minute intervals, through a 40-minute period while resting supine Ten young male hospital inpatients without cardiovascular disease and 10 young male laboratory personnel served as subjects The entire routine was repeated on the inpatients the following day A significant elevation of mean cardiac index (12%) occurred within $\frac{1}{2}$ hour after eating which lasted 3 $\frac{1}{2}$ hours There was no difference between inpatients and laboratory personnel, in either the basal state or following ordinary activity, and there was no change through forty minutes of rest, similar results were obtained on the second day The reliability of the cardiac index was high and variation in any case determination depended largely on the complexes chosen No significant advantage was obtained by increasing the number of complexes measured or the number of observers

Adrenal cortical hormone levels in blood following 'alarming stimuli' K E PASCHKIS, A CANTAROW and D BOYLE *Jefferson Medical College, Philadelphia, Penna* The reaction of the adrenal cortex to 'alarming stimuli' was studied by assay of adrenal cortical hormone in peripheral arterial blood of dogs Hormone levels were determined in plasma by the mouse liver glycogen method of Venning It had been shown previously (*Fed Proc* 7:90, 1948) that levels in the arterial blood rise following the injection of ACTH or of adrenalin A rise of cortical hormone in arterial plasma occurred within the first hour after subcutaneous injection of formalin A surgical procedure, exposure of the adrenal gland under anesthesia, resulted in higher levels of cortical hormone in the adrenal vein blood than had been previously obtained in the unanes-

thetized, trained dog (London cannula) Insulin injection was followed by an increase in cortical hormone, suggesting the participation of adrenal cortical hormone in counteracting insulin-induced hypoglycemia Attempts to determine whether the effects of these stimuli were mediated by epinephrine (according to the theory of Long) led to an investigation of the action of Debenamine in this connection Injection of Dibenamine itself was found to be an 'alarming stimulus', leading to an increase in blood levels of cortical hormone The effect of sympathetic blockade by Dibenamine upon the response to formalin and insulin was studied

Influence of a conditioning injection of estrogen on the hematologic and organ weight response to X-irradiation HARVEY M PATT, MARGUERITE N SWIFT (by invitation), ROBERT L STRAUBE (by invitation), ELLA B TYREE (by invitation) and DOUGLAS E SMITH *Biology Division, Argonne National Lab, Chicago, Ill* Estradiol benzoate (0.166 mg I/M) in a single injection 5 to 15 days before exposure greatly enhances resistance of mice to total body X-irradiation Progesterone and testosterone are ineffectual To elucidate this phenomena we have studied the effect of estradiol on organ weights, blood count, and microscopic anatomy in control and irradiated mice Estrogen increases adrenal weight by 35-40% 4 days after injection and accelerates thymic involution but has no appreciable effect on weight of spleen, inguinal nodes or kidney Leukopenia with maximal depression around 10-14 days after injection has also been observed Decreases are noted in lymphocytes and heterophils Little change is seen in erythrocytes Significantly, the maximal estrogenic protective effect is observed when mice are irradiated during their leukopenic period Estrogen injection at the time of irradiation or 25 to 35 days before exposure does not protect Radiation induced involution of spleen, thymus and inguinal nodes is not altered by estradiol However, the increase in adrenal weight is somewhat greater in these animals Leucocytes are decreased equally in both estrogen and control (sesame oil injected) irradiated animals, although maximal depression and recovery occur somewhat earlier in the former Erythrocyte count of irradiated controls is decreased by 45% at 11 and 14 days after exposure Estrogen treated animals manifest a smaller decrease in red count (25%) 7 days after irradiation and normal levels at 11 and 14 days The possibility that the protective action of estrogens is mediated by the adrenals is being investigated

Oxygen consumption and water balance in the X-irradiated frog HARVEY M PATT, MARGUERITE N SWIFT (by invitation) and ELLA B TYREE (by invitation) *Biology Division, Argonne National Lab, Chicago, Ill* As part of a study of the radiation response of frogs and of factors contribut-

ing to their radiosensitivity, we have investigated 1) oxygen consumption after X-irradiation, and 2) rate of water uptake in dehydrated irradiated frogs Oxygen consumed by individual unfed Autumn frogs, sedated with nembutal, was measured volumetrically at atmospheric pressure and 23°C Results of a pilot study in which determinations were made during a control period of several days and at frequent intervals after X-irradiation with 3000 R (completely lethal, mean survival time 28 days), suggest a slight early decrease in oxygen consumption with maximal depression (34%) 15 days after exposure This is followed by return to control levels (0.086 ± 0.002 cc/gm/hr) around 25 days after irradiation Although there is evidence that ionizing radiation accelerates catabolism in mammals, especially terminally, we failed to observe any increase in oxygen consumption in these frogs Body weight of unfed irradiated frogs also did not change appreciably Frogs kept in dry individual containers at 23°C for 3 days lose 35-40% of their water After irradiation with 3000 R and immediate return to water, such partially dehydrated irradiated frogs regain water at the same rate as non-irradiated dehydrated controls In both groups, recovery is essentially complete by 4 hours There is no change in water content of non-dehydrated irradiated frogs over this period Experiments are in progress to evaluate the influence of water content at the time of exposure on radiosensitivity in the frog

Effect of urine extracts from hypophysectomized dogs on gastric secretion T L PATTERSON, J KAULBERSZ, D J SANDWEISS and H C SALTZSTEIN (by invitation) *Depts of Physiology and Surgery, Wayne Univ College of Medicine and Harper Hospital, Detroit, Mich* In continuation of our earlier studies related to the influence on gastric secretion of urine extracts from dogs deprived of their pituitary gland, new series of experiments were made with extracts prepared from dogs hypophysectomized by transtemporal methods The effect of the extracts were tested on several dogs either with gastric fistula or with Heidenhain pouch by the double-histamine technique In 21 experiments (*series A*) the extract was administered during the second period of the double-histamine test, and in 25 experiments (*series B*) during the first period Extracts from the urine of hypophysectomized dogs did not exhibit a prompt inhibitory effect which is characteristic for urogastrone prepared from normal urine In relatively small doses (1 mg) hypophysectomized extracts produced as an immediate effect an increase in secretory response to histamine which is statistically significant in both animal series No significant delayed effect on secretion could be detected In larger doses (3 mg or more) there was no significant immediate effect on secretory response to

histamine, although in some dogs varied degrees of stimulation or inhibition were observed. However, statistically significant evidence of a strong delayed inhibition lasting more than 9 hours is revealed. Therefore, it appears that urine extracts prepared from hypophysectomized dogs contain both stimulatory and inhibitory agents. The stimulatory effect is prompt and more noticeable in small doses. The inhibitory effect is more evident in larger doses of the extract. In contrast to that of typical urogastrone, inhibition develops slowly and lasts longer than 9 hours.

Manifestations of potassium intoxication in the dog heart-lung preparation FRANCIS E. PAYNE (by invitation), LESLIE L. BENNETT, SANDOR G. BURSTEIN (by invitation), and JAMES HOPPER, JR. (by invitation). *Divisions of Physiology and Medicine, Univ. of California, Berkeley and San Francisco, Calif.* Heart-lung preparations were arranged for the continuous recording of right auricular pressure, aortic pressure, ventricular volume, and left ventricular output minus the coronary flow. Unipolar electrocardiographic tracings were taken directly from the anterior surface of the left ventricle using a wick electrode. The plasma potassium concentration was elevated by the addition of isotonic KCl and the plasma level was determined by the use of a flame photometer. Eight heart-lung preparations were studied. The venous return and peripheral resistance were not altered during an experiment. It was found that the major mechanical phenomena of potassium intoxication did not appear until a plasma level of approximately 7 mEq/l was reached. While approaching this level of potassium concentration only minimal increases in ventricular volume and minimal decreases in cardiac rate and output were observed. During this period of increasing potassium concentration there were progressive electrocardiographic changes which consisted of decreased amplitude of P waves and QRS complexes, depression of the S-T segments, prolongation of the P-R intervals, and increased amplitude of the T waves. When potassium levels of approximately 7 mEq/l were reached the following marked changes of abrupt onset occurred: increase in right auricular pressure, ventricular volume, and aortic pulse pressure (reflecting the increased stroke output due to the slow rate), and decrease in cardiac output and heart rate (the result of auricular standstill). The most striking associated electrocardiographic changes were the disappearance of the P waves, further displacement of the S-T segments and still higher T waves.

Hepato-renal factors in circulatory homeostasis

XXV. Low protein diets and renal VEM formation MARY ANN PAYNE (by invitation) and EPHRAIM SHORF. *Dept. of Medicine, Cornell Univ. Medical College and The New York Hospital, New York City.* Previous studies from this laboratory demon-

strated the importance of the renal vasoexcitor, VEM, for compensatory peripheral vascular reactions to hemorrhagic and traumatic shock, in its absence, these compensatory reactions failed to occur. Under certain conditions the renal capacity to form VEM was abolished, e.g., anoxia (2 hours for rat, 4 for dog kidney), adrenal insufficiency and nutritional cirrhosis (rats, on 10% protein diets for 4 months). The present study deals with the acute effects, in rats, of fasting and a lower protein diet (5% casein) on the renal capacity to form VEM, as measured by anaerobic incubation of kidney slices *in vitro*. Adequate vitamin supplements were supplied throughout. Fasting rats sustained a significant reduction in the capacity to form VEM by the 4th, and a total loss by the 6th day of the fast. Those receiving the 5% casein diet showed appreciable reductions in VEM formation by the 8th, and complete abolition from the 12th through the 39th day, when the experiment was terminated. Desoxycorticosterone acetate, which restores VEM formation to kidneys of adrenalectomized rats, failed to prevent this defect, when given from day 1 to 14, or to correct it, when given from day 14 to 39 of the low protein regime. This VEM defect was not associated with significant reductions in renal oxygen consumption. It is suggested that, in addition to the adrenal cortical hormones and an aerobic environment, an adequate protein intake is essential for the integrity of the renal mechanism for forming VEM.

Studies on the fat-mobilizing hormone of the anterior pituitary gland RICHARD W. PAYNE (introduced by E. B. ASTWOOD). *Joseph H. Pratt Diagnostic Hospital, and Dept. of Medicine, Tufts Medical School, Boston, Mass.* The fat-mobilizing effect of various anterior pituitary preparations was assayed by fat deposition in the livers of fasted mice by the method of Campbell (*Endocrinology* 23: 692, 1938). Increasing doses induced a progressive increase in the liver fat from control values of 4.5 to 6.0% to maximal values of 12.0 to 14.0%. Higher doses caused a submaximal response. Some activity was found to be present in all anterior pituitary preparations tested (whole beef anterior pituitary and pork and sheep pituitary powders, Armour and Parke-Davis thyrotrophic hormone, Armour's adrenocorticotrophic hormone, Armour's growth hormone, and Searle's anterior pituitary gonadotrophic hormone). Posterior pituitary preparations showed no fat-mobilizing properties. Purified adrenocorticotrophic and thyrotrophic hormones were the most active on a weight basis. Purified growth hormone and gonadotrophic hormones showed little activity as compared to other purified preparations. One week after adrenalectomy, the test animals exhibited no fat-mobilization in response to any anterior pituitary preparation. Thyroidectomy or depression of thy-

roid function with propylthiouracil did not inhibit the effect. Single injections in oil of progesterone (10 mg), testosterone (25 mg), desoxycorticosterone acetate (5 mg), and stilbestrol (5 mg) had no effect. One cc of aqueous adrenal cortical extract produced no significant fat-mobilizing effect.

Comparison of a volumetric respirometer with the Warburg method in measurement of brain respiration

C. N. PEISS and R. WENNESLAND (introduced by J. FIELD) *O. N. R. Arctic Research Lab., Point Barrow, Alaska, and Dept. of Physiology, Stanford Univ., Stanford, Calif.* Six aliquants (each about 25 mg wet weight) of rat cerebral cortex slices were prepared from the brains of each of 8 adult albino rats. The moist cold box technique was used (Field, *Methods in Medical Research*, 1948). Oxygen uptake was measured on 3 aliquants by the Warburg method and on the other 3 by means of volumetric respirometers (see abstract by Wennesland). Thus 48 Warburg runs were made and 47 volumetric (one sample lost). The liquid phase was Krebs Ringer's phosphate containing 0.01M glucose and 0.01M bicarbonate. Gas phase oxygen. Temperature $37.5 \pm 0.01^\circ\text{C}$. Initial pH 7.4. Final pH 7.4 to 7.5. The mean Q_{O_2} s were 14.12 and 14.08 for the Warburg and volumetric methods respectively. The corresponding standard errors were ± 0.169 and ± 0.171 . Statistical analysis showed that the two series did not differ significantly either in respect of the means (Student's 't' test) or of the variability (Fisher's 'F' test).

Blood gas content of dogs during immersion hypothermia

K. E. PENROD and FELIX R. ROSENHAIN (by invitation) *Dept. of Physiology, Boston Univ. School of Medicine, Boston, Mass.* Simultaneously drawn samples of arterial blood from the carotid artery and mixed venous blood from the right ventricle were handled anaerobically and analyzed for O_2 and CO_2 content. Samples were drawn before immersion in an iced bath and at rectal temperatures of 30° , 25° and 20°C while breathing air, and before immersion, at 35° , 30° and 25°C in a second series breathing 100% O_2 . All dogs were lightly anesthetized with sodium pentothal. Hematocrit determinations were made on each blood sample. In 2 of 9 dogs breathing air a mounting arterial CO_2 , evidence of approaching respiratory inadequacy, appeared above 25°C rectal temperature. In 4 it was between 25° and 20° and in the other 3 below 20°C . Beginning circulatory inadequacy was not yet evident at 20°C rectal temperature in 7 of 9 dogs. In one it occurred between 25° and 20° and in one failure was progressive during the entire period of immersion. In 5 of 8 dogs surviving to below 20°C the venous O_2 content at 20° was equal to or greater than pre-immersion levels. Hematocrits showed a 20% increase during hypothermia which is partially accounted for by pentothal depression of the control value. When breath-

ing 100% O_2 throughout the hypothermic period 4 of 9 dogs showed some respiratory failure above 25°C . In nearly every case respiration was depressed throughout, as reflected in a high arterial CO_2 content. Circulatory impairment was evident in only 1 dog at 25°C . The venous O_2 content was higher at 25°C in 7 of the 9 dogs than it was before immersion.

Cooling as a stimulus to certain smooth muscles

JOHN F. PERKINS, JR. and CHARLES H. NICHOLAS (introduced by R. W. GERARD) *Dept. of Physiology, Univ. of Chicago, Chicago, Ill.* Cooling alone causes contraction of the retractor penis muscle of the dog (De Zilwa, *J. Physiol.* 27: 200, 1901), of the cat's nictitating membrane (Perkins and Li, *Fed. Proc.* 7: 1948) and apparently also of the smooth muscle of the arteriovenous anastomoses of the skin (Perkins et al., *Am. J. Physiol.* in press). Further studies were made on the dog's retractor penis, which was placed in Tyrode's solution in a jacketed bath. Temperature was measured by a thermistor in contact with the muscle. Provision was made to cool the muscle gradually, or rapidly, from 36°C down to as low as 0°C . Cooling alone acts as a stimulus, producing as quick a contraction as that caused by epinephrine. Rapid cooling is a more effective stimulus than gradual. When degrees of rapid cooling (abscissae) were plotted against heights of contraction, an S-shaped curve resulted, with a maximum at 24° of rapid cooling (cooling from 36 to 12°C). Lowering the pH to near 7 causes a gradual, marked contraction, on which the effect of cold can be superimposed. The separate effects of epinephrine and of cooling are additive when tested together. After Dibenamine the muscle lengthens with epinephrine but still shortens with cold. With both together, the effects tend to cancel (algebraic addition). Thus, cold apparently acts on a different excitatory system than epinephrine, or else it acts directly on the contractile system. Against a direct action is the failure of rabbit intestine, uterus, aorta, and iris to contract when cooled.

Effect of estrogen and relaxin on the connective tissue of the pubic symphysis

E. PERL (by invitation) and H. R. CATCHPOLE *Dept. of Pathology, College of Medicine, Univ. of Illinois, Chicago, Ill.* Female guinea pigs castrated for 1 month were treated daily for 4-5 days with $1.0\text{ }\mu\text{g}$ estradiol, then given an injection of pregnant rabbit serum containing relaxin. Following relaxation (6-8 hours) each of one group of animals received intravenously 4.0 ml 1.25% Evans blue (intravital) dye, and was killed 10 minutes later. The symphysis was frozen in liquid air and frozen-dried *in vacuo*. The dried block was embedded in paraffin and sectioned at $120\text{ }\mu$. Uninjected controls and animals receiving estrogen only were similarly studied. In another group, symphyses of control, estrogen treated and

estrogen-relaxin treated animals were frozen-dried, embedded as above, sectioned at 5-10 μ and stained for glycoproteins by the McManus-Hotchkiss periodic acid-leucofuchsin reagent. Connective tissue between the symphyseal cartilages is unstained by Evans blue in control, and virtually unstained in estrogen treated animals, in the anterior and posterior notches bordering the symphysis, estrogen treated animals show slight staining. Following relaxin the connective tissue of the joint proper stains more or less blue in all cases and that of the notches stains very markedly. The glycoprotein material of the symphysis, which stains with periodic acid-leucofuchsin reagent, was found to become more soluble in aqueous solvents following relaxin. The interpretation is made that relaxin induces breakdown (depolymerization) of the glycoproteins of the symphyseal region, which provides the physical basis for relaxation, these components become more water soluble and are able to bind Evans blue.

Mixing time of Brilliant Vital Red injected into dogs. RAYMOND W. PICKERING (by invitation) and PHILIP DOW *Dept of Physiology, Univ of Georgia School of Medicine, Augusta, Ga.* The mixing time of intravascular dyes injected into normal animals has long been controversial. Its prolongation in circulatory collapse has been recognized but not (so far as we have found) quantitatively measured. An opportunity to obtain estimates of both was presented in the course of efforts to follow fluid shifts during serial hemorrhages in dogs (currently reported by Remington). Following a rapid jugular injection of Brilliant Vital Red, samples at frequent intervals were drawn simultaneously from a femoral artery and the corresponding vein. Under control conditions, arterial dye concentrations declined and venous concentrations rose, the two becoming acceptably identical after four minutes. After an estimated 35% hemorrhage (7 steps, 1 hour) the results were highly variable. In one type the concentration curves were like controls in form but greatly prolonged, their slow approximation permitting an estimate of dilution volume only after 20 to 30 minutes. In another type both arterial and venous concentrations continued to rise for 30 minutes, suggesting sequestration elsewhere and slow mixing of a large fraction of the injected dye. When supplementary samples from the non-injected jugular were added to the series they coincided with the arterial curve and would thus have given false assurance of mixing had they been the only ones available for comparison. The results emphasize the hazardous aspect of estimating completeness of mixing from a series of samples from any single vessel. They supplement and extend the previous observations of the Greger-en group and of Phillips.

Potent pressor action of an extract of a phaeo-

chromocytoma after adrenolytic doses of Dibenamine. D. M. PITCAIRN (by invitation) and W. B. YOUNG *Dept of Physiology, Univ of Oregon Medical School, Portland, Ore.* A 13-year-old boy with severe and relatively sustained arterial hypertension was given Dibenamine, and the blood pressure decreased rapidly to the normal range with the patient remaining in the supine position. Following surgical removal of the left adrenal gland, which contained a phaeochromocytoma, his hypertension was relieved. An aqueous extract of the phaeochromocytoma was prepared 2 hours after removal, and effects of the extract upon the blood pressure of dogs under pentobarbital sodium were determined before and after Dibenamine. The extract had a very potent pressor action which was not blocked by full adrenolytic doses of Dibenamine. The pressor substance was present in slightly diminished amount in the refrigerated phaeochromocytoma 24 hours later, and a relatively small amount was detected after 5 days. Extracts of the thin layer of cortex, which could not be cleanly separated from the phaeochromocytoma, had much less pressor potency than extracts from the central portion of the tumor. Aqueous extracts of fresh normal dog and beef adrenal medulla, like epinephrine, had pressor action before Dibenamine and depressor action after Dibenamine. Aqueous extracts of dog and beef adrenal cortex produced either a slight fall in blood pressure or no response following Dibenamine. Persistence of the major part of the pressor action of the extract of the phaeochromocytoma after Dibenamine indicates the presence in the tumor of a considerable amount of a pressor substance other than epinephrine.

Filtration rate and sodium and water excretion following mercurial diuretics. ROBERT F. PITTS and JOHN J. DUGGAN (by invitation) *Dept of Physiology, Syracuse Univ College of Medicine, Syracuse, N. Y.* The rate of elimination of sodium and water by the normal human subject following the intravenous administration of 2 cc of mercurhydrin is determined in part by the glomerular filtration rate. Two subjects hydrated with 500 cc of water per os prior to the start of the experiment showed evidence of mild to severe peripheral circulatory failure from 1.5 to 2.5 hrs following the mercurial. Glomerular filtration rate was depressed during the period of circulatory collapse, as was the rate of excretion of sodium and water. When the subjects were hydrated by the infusion of saline at 10 to 15 cc per min for 2 hr prior to the start and throughout the course of the experiment, glomerular filtration was maintained at a normal or elevated rate for the subsequent 5 hr period of observation. The quantities of salt and water eliminated in the latter experiments far exceeded those of the preceding ones. Salt and water balances and hematocrit changes suggest that diuresis in the

water hydrated subjects rapidly reduced circulating blood volume and led to circulatory collapse with its attendant fall in filtration rate. A greater fluid reserve in the saline hydrated subjects, prevented these changes. It is inferred that a decrease in filtration rate is attended by reduced delivery of proximal tubular fluid into the distal segment, the sodium and water absorptive capacity of which is depressed by mercurial diuretics. Accordingly little sodium and water may be excreted even though distal absorption is severely curtailed.

Macrophage promoting factor (MPF) in mammalian blood serum. C. M. POMERAT and M. F. ORR (by invitation) *Tissue Culture Lab, Medical Branch, Univ. of Texas, Galveston, Texas.* Fragments of spleens from 18-day chick embryos approximately 1 mm square show a circular zone of migrating cells about 5 mm in diameter within 24 hours when cultivated at 37°C in a clot formed of cockrel plasma and chick embryo extract. The peripheral elements of such cultures consist of myelocytes with acidophilic granules. While the inclusion of 25% mammalian serum in the composition of the medium gave typical cultures, it was found that the blood of some rabbits induced the appearance of large numbers of highly phagocytic cells which engulfed all outwandering myelocytes within 24 hours. This macrophage promoting factor (MPF) has been found to be thermolabile, precipitated by 1/3 saturated ammonium sulfate and to be present in an acetone insoluble fraction. It does not appear to be related to the Forssman antigen or to anti-organ sera with high or low complement fixation or hemolytic titres. It was not found possible to reproduce the phenomenon of macrophage induction under the conditions described with the use of various concentrations of histamine, 17-hydroxy-11-dehydrocorticosterone, choline or various quaternary ammonium compounds. MPF does not appear to be identical with leucotoxin, the leucocyte-promoting factor, necrosin, pyrexin or the leucopenic factor which have been found by Menkin in experimental inflammatory exudates.

Estimate of the kinetic and potential energy of the work of the human heart. O. PREG (by invitation), L. N. KATZ, R. ROSENMAN (by invitation) and L. W. SENNETT (by invitation) *Cardiovascular Dept., Medical Research Inst., Michael Reese Hospital, Chicago, Ill.* The recent techniques of angiocardiology and right heart catheterization offer data from which an approximate calculation of the work of the human heart may be determined from the formula $W = \left(PV + \frac{Mv^2}{2g} \right)_L + \left(PV + \frac{Mv^2}{2g} \right)_R$.

The significance of the various symbols are those currently accepted. V and M are calculated from the Fick formula, v is calculated from the stroke output, cross sectional area of the aorta, just above the sinuses of Valsalva, and of the pulmonary ar-

tery, and the ejection time. The last is obtained from the pressure pulse within the main pulmonary artery. Data on a typical case are as follows: aortic diameter, 3.10 cm, pulmonary artery diameter, 3.23 cm, stroke output, 104 cc, ejection period, 0.26 sec, mean aortic pressure (estimated), 135 mm Hg, mean pulmonary arterial pressure, 14 mm Hg. Work in gm cm/sec = $18,250 + 160 + 1900 + 130 = 20,440$. Kinetic energy equals 6.8% of the total work of the right ventricle, and 0.9% of the left ventricle. The kinetic energy equals 1.4% of the total work of both ventricles.

Studies on the accuracy of pressures recorded through a catheter. W. H. PRITCHARD (by invitation), R. W. ECKSTEIN, R. ECKEL (by invitation), C. L. PARSONS (by invitation) and T. E. LOWE (by invitation) *Western Reserve Univ., Dept. of Medicine, Cleveland, Ohio.* The wide use of the catheter for pressure recording demands a critical comparison of its recorded curves with those recorded by more adequate means. For these studies, pressures were recorded through catheters connected to a high frequency Gregg optical manometer (with and without various lengths of intervening lead tube). These were compared to pressures simultaneously recorded through large needles connected by short lengths of lead to a second Gregg optical manometer. Pressures were measured in a diaphragm type of pump, and the right ventricle of the anesthetized open chest dog. With the pump perfect pressure agreement occurred at slow pump speeds. Higher speeds and the addition of lead tube produced artefacts with marked overshooting and unreadable curves. Time lags were small, from 0.008 to 0.015 sec. In the dog the catheter also produced overshooting with secondary oscillations making true pressure estimations impossible. This inaccuracy was accentuated by the addition of 1 or 2 meter lengths of lead tube. The curves were markedly improved when a certain degree of clotting occurred in the catheter tip. Therefore, damping was done by partially closing a stopcock placed between the catheter and manometer. At damping coefficients of about 7 accurate readable curves were obtained. Readable curves were also obtained from the human right ventricle after ideal damping with a stopcock.

Heat loss and heat production of cats at different environmental temperatures. LAWRENCE R. PROUTY (introduced by EUGENE F. DU BOIS) *Dept. of Physiology, Cornell Univ. Medical College, New York City.* Shaved, unanesthetized cats were studied during 77 one-half hour periods in environments ranging from 19° to 39°C. have shown that the thermoregulatory mechanisms of a cat differ greatly from man and that the cat is a poor laboratory subject for the study of human temperature regulation. Simultaneous determinations of respiratory metabolism, heat loss, rectal and average skin

temperatures and thermal conductance were made in the gradient calorimeter previously described (Prouty, Barrett and Hardy *Fed Proc* 7 96, 1948) Relative humidity was kept low enough not to interfere with the efficiency of the evaporative process As environmental temperatures were decreased below thermal neutrality, heat loss became progressively greater than heat production In 20 experiments between 20° and 24°C heat loss was 16% greater Vaporization values of 9 to 15 gm/m²/hr were approximately the same in this range as in the zone of thermal neutrality Man can alter peripheral thermal conductance 5-6 fold but the cat shows a relatively flat conductance curve until it licks itself In the cold, the cat relies upon the protection of its fur and the ability to decrease its surface area or increase its heat production Without fur, rectal temperature drops to 35°C then falls precipitously and death would result if the animal could not find a warmer climate As environmental temperature is increased above thermal neutrality, heat production becomes increasingly greater than heat loss At 38.5°C, it is 75% greater At 39°C, respiration approximates 200/min after 2 hours There is a rapid rise in rectal temperature to 43.9 and skin temperature to 43.5°C The animal does not sweat appreciably but coats accessible parts with saliva Nausea, vomiting and convulsions occur and the animal must be removed quickly

Effect of protein in the diet upon certain aspects of renal function THEODORE N. PULLMAN (by invitation), ALF S. ALVING, and MILTON LANDOWNE *Dept of Medicine, Univ of Chicago, Chicago, Ill* Ten normal young adults were placed on each of 3 diets, containing different amounts of protein, for successive 2-week periods The low, intermediary, and high protein regimens contained respectively 0.3-0.4, 1.0-1.1, and 2.3-3.0 gm of protein/kg of body weight/day Simultaneous inulin and diodrast clearances were determined after 2 weeks on each diet Eight subjects showed higher glomerular filtration rates on the high than on the medium protein diet, the total average increase being 21.9% This difference was highly significant statistically Six subjects showed lower glomerular filtration rates on the low protein than on the control diet, but the average difference could not be proved significant Seven individuals showed a higher renal plasma flow on the high than on the medium protein diet, the total average increase being 20.0% This difference was also statistically of high significance Eight subjects had lower renal plasma flows on the low than on the control diet, but the average difference could not be proved significant No significant change in filtration fraction occurred Preliminary studies on 6 subjects indicate that urea clearances are lower on the low protein diets and that such changes cannot be accounted for solely by diminution in the glomerular filtration rate In all groups,

the tubular reabsorption rate of urea seemed related linearly to the filtration rate of urea, the slope being higher when dietary protein was low than when medium or high This relation is currently under further investigation

Effects of unequal blood flow and ventilation upon the alveolar-arterial gradient HERMANN RAHN *Dept of Physiology and Vital Economics, Univ of Rochester School of Medicine and Dentistry, Rochester, N Y* It has previously been shown that, given a mixed venous blood gas content and inspired air tension, all the possible simultaneous combinations of pO₂ and pCO₂ existing in the lung or parts thereof can be determined If the metabolic R Q is known then in addition the mean alveolar air composition can be defined Any particular alveolar gas tension is determined by a definite ratio of alveolar ventilation (V) to pulmonary blood flow (F) When both of these quantities are measured in the same units then

$$\frac{V}{F} = \frac{864 \times (A-V) \text{ O}_2 \text{ difference} \times R Q}{\text{alv pCO}_2}$$

Thus a mean alveolar gas composition is determined by a definite mean V/F ratio But to calculate the mean arterial pressures one needs to know not only the alveolar pO₂ and CO₂ produced by the mean V/F but also by the variance of V/F This variance is determined by the degree of unequal pulmonary perfusion and alveolar ventilation While the gradient for CO₂ is negligible, the O₂ gradient depends upon the magnitude of the deviations assumed

Relations between blood flow, skin temperature, evaporation rates and sweating in various skin regions WALTER C. RANDALL and ALRICK B. HERTZMAN *Dept of Physiology, St Louis Univ School of Medicine* Simultaneous measurements of cutaneous blood flow, evaporation rates, and surface temperatures following mecholyl iontophoresis suggested certain important correlations between these functions in maintaining thermal flows at the skin surface In these experiments involving high sweating rates, the skin may be partitioned into three zones 1) areas such as the dorsal surfaces of the hand and foot where sweating rates provide for an evaporative heat loss in excess of the heat delivered by the blood, 2) surfaces of the face where sweating rates are low with relatively high blood flows, 3) areas of the trunk where both maximal blood flows and sweating rates are intermediate between these extremes The largest total surface area falls within the latter group Calculations of total possible evaporative heat losses if all the sweat were vaporized from each of these areas suggest a marked initial thermal deficit on the part of the cutaneous blood flow Part of this deficit may be corrected by direct conduction from deeper tissues Such thermal deficits have been observed immediately following stimulation of the sweat glands and blood vessels by mecholyl, but the deficit rapidly de-

creases to a point where appropriate caloric balances may be established

IV An electronic, multi-range, multi-channel, direct-writing pressure recorder MAURICE RAPAPORT and STANLEY J SARNOFF (introduced by WILLIAM H FORBES) *Dept of Physiology, Harvard School of Public Health, Boston, Mass* An apparatus has been developed which combines the characteristics thought to be desirable in a pressure recording apparatus 1) Linearity over all pressure ranges 2) Small fluid shift with change in pressure (0.02 mm ³ for 100 mm Hg) Change of sensitivity without changing the natural frequency of the system thus enabling full-scale deflection for 400 mm Hg, or for 1 mm Hg pressure change (with appropriate intermediate sensitivities) by simple adjustment of the amplification circuit 3) Recording by means of a direct-writing galvanometer 4) Rectilinear rather than curvilinear coordinates 5) Multi-channel recording 6) Portability of the single channel apparatus 7) Multiple chart speeds ranging from 0.25 mm to 50 mm per second with intermediate speeds 8) Sterilizability of all components in contact with the fluid system 9) Additional recording channels for synchronization with the electrocardiogram, pneumotachogram, pneumogram, and phonocardiogram, electrokymogram, etc The pressure pick-up is a condenser microphone which is an element of an alternating current bridge, operating at radio frequencies When zero pressure is applied to the pressure pick-up, the bridge is balanced and the output from it is zero When pressure is applied, the bridge is proportionately unbalanced, and a voltage output therefore occurs across the bridge This voltage is amplified and rectified and fed into a direct writing or photographic galvanometer

Multiple avitaminosis-like syndrome produced by adenine SIGWIN B RASKA *Dept of Pharmacology, Univ of Mississippi School of Medicine, University, Miss* Orally administered adenine in daily doses of 30 to 50 mg/kg given for a period of about 3 to 5 weeks produces the syndrome of multiple avitaminosis in dogs receiving complete normal diets both before and during the experimental period (Raska, *Science* 105 1947, *J Biol Chem* 165 743, 1946) Gross and microscopic examination of the tissues of these animals disclosed the following scattered areas of atrophy of the epithelium of the inner surface of the lip with dense cellular infiltration in the underlying tissue, general atrophy of the buccal mucous membrane with erosion in the depth of the buccal folds and moderate inflammatory leucocytic infiltration in the subepithelial tissues, varying grades of necrosis of the tongue, from moderately severe to marked, characterized by extensive pyknosis and even by obliteration of cross-striations and fibrils as the consequence of coagulation necrosis of the muscle fibers,

extensive necrosis of the gastric mucosa extending as deeply as the muscularis and accompanied by considerable hemorrhage in the necrotic tissue, deposition of brownish crystalline material in the distal convoluted tubules and collecting tubules of the kidney and monocytic infiltration in the interstitial tissue, deposition of calcareous material in some tubules, granulomatous lesions scattered throughout the renal cortex, moderate congestion of the pancreas, considerable congestion of the adrenal medulla and the liver In these animals, blood NPN, blood urea and blood uric acid were markedly elevated Oliguria and abnormal urinary findings (e g, large numbers of WBC, hyaline casts and large amounts of amorphous sediment) were present In the early stages, arterial blood pressure was moderately but definitely increased The motor activity of the animals indicated pathologic changes in the central nervous system Vitamins of the B complex were able to counteract partially the effects of adenine only in the early stages of the syndrome

Age and kidney renin in rabbits G CARL RAU (introduced by M M ELLIS) *Dept of Physiology and Pharmacology, Univ of Missouri Medical School, Columbia, Mo* Grossman and Williams (1938) reported that kidneys of young rats contained more renin than those of older rats, using extracts which were not hypertensinase-free and may have contained other pressor substances, for Helmer and Shipley (1947) suggest that kidney contains another pressor principle distinct from but extractable with renin It seemed desirable to determine whether the amount of renin alone in the kidney varies with age, using extracts prepared by newer methods and known to be free from other pressor substances and hypertensinase With modifications the preparation of renin, hypertensinogen and hypertensin, and the assay procedures were according to Dexter, Haynes and Bridges (1945) Sixty rabbits of three age groups, 20-24, 180 and 365 days old, were used, i e, two groups of immature and one of adult rabbits Each group of 20 was divided into two lots of 10 and the renin extracted from the pooled kidney masses of each lot On the basis of gram of kidney, considering the 365 day group as 1, the renin yield for the 180-day group was 5 and for the 20 to 24-day group, 2 When the proportional kidney weight was used, i e kidney weight divided by body weight, the renin yield per gram of kidney, considering the 365-day group 1, was 5 for both the 180 and the 20 to 24-day group The renin content of kidneys of immature rabbits as found was definitely greater than that of adult rabbits

Effect of position upon the respiratory rate of anesthetized dogs E A REED and J C SCOTT *Dept of Physiology, Hahnemann Medical College, Philadelphia, Penna* Respiration was recorded by

a tambour and endotracheal tube in dogs anesthetized with nembutal. Oxygen was supplied by a second endotracheal catheter. Compared with the lateral, the supine position usually increases the rate while the prone markedly decreases it. The rate is greatly increased in the supine position by tilting head downward 27° . Tilting head upward 27° decreases the rate. The head upward and the prone positions may completely inhibit respiration for several minutes. A return toward the rate of the previous position occurs during the first few minutes. When the change of position is one producing acceleration, the increased rate during the first minute may be due partly to extraneous stimulation from handling the animal. However, when the change of position produces a decreased rate, the same apparent adaptation proceeds in the reverse direction. Bilateral cervical vagotomy greatly reduces or abolishes rate changes due to position. In many cases, the effect of the prone and the head downward positions is reversed. In most instances, there is an acceleration lasting for approximately one minute after change to any position. Rate changes in the intact animal are probably due mainly to the Herring-Breuer reflex. The cranio-ventral slope of the diaphragm would permit compression of lung tissue by gravity shift of abdominal viscera when the animal is in the supine position and distension when in the prone position. Elevation or depression of the head end of the animal also distends or compresses lung tissue by shift of abdominal viscera.

Reduction of the plasma potassium concentration by vivodialysis and its restoration in non-visceral regions. ROGER M. REINECKE and FRANCIS L. STUTZMAN (by invitation). *Dept of Physiology, Univ of Minnesota, Minneapolis, Minn.* The arterial plasma potassium level of the dog was substantially reduced by vivodialysis. Concurrently there was a definite arterio-venous increase in the plasma potassium concentration of blood flowing through the hind limb. This arterio-venous increase was also found for blood flowing through a muscle that had been isolated from the body except for its blood and nerve supply.

Hemodynamic changes in response to hemorrhage with and without Dibenamine. JOHN W. REMINGTON. *Dept of Physiology, Univ of Georgia School of Medicine, Augusta, Ga.* Circulatory changes accompanying serial hemorrhages have been followed in 20 control dogs, and in 16 animals given Dibenamine. On the average, the first of the 6 or 7 bleedings (5 cc/kg each, at 10-min intervals), was followed by a 7% fall in mean blood pressure (optical manometer) and a 26% reduction in flow (calculated from pressure pulse contour), indicating 18% increase in resistance. Mean pressure was then held almost constant through the 4th hemorrhage, while flow declined slowly to -39%,

and resistance increased to +30%. Cardio-acceleration started usually after the 2nd hemorrhage, reaching its maximum after the 5th. In the late hemorrhages, when pulse rate was nearly maximal, mean pressure declined rapidly, with a reduction in resistance to pre-hemorrhage levels. The changes in the above factors were parallel in the two groups, which did not differ significantly. During the cardio-acceleration, the fraction of total blood volume held in the heart and lungs (measured by the dye injection technique) was reduced. X-ray heart volume and electrocardiographic changes in the two series are being studied. There was little if any dilution of the plasma (falling drop) until after the 4th hemorrhage, when dilution began at a rapid rate. The causal basis of the time of onset and the degree of dilution are not clear. Central venous pressure declined during the early hemorrhage, but later changes were variable.

Analysis of out-of-doors thermal stress due to radiation with the pan-radiometer. CHARLES H. RICHARDS (by invitation) and JAMES D. HARDY. *New York Hospital and the Dept of Physiology, Cornell Univ Medical College, New York City.* The fact that the solar spectrum and the emission spectrum of the low temperature radiation of the environment do not overlap appreciably makes it possible to measure separately these sources of radiant energy with the pan-radiometer. This instrument now consists of 3 hollow silver spheres, each containing a heating coil and thermocouple. The outer surface of one sphere is highly polished, a second is dull black, and the third is matte white reflecting the sun's radiation. When this instrument is exposed out of doors in sunlight, the black sphere becomes warmest, the polished sphere next and the white sphere least. Heat is put into the white and polished spheres bringing them to the temperature of the black sphere. From a measurement of this heat and the black sphere temperature the following can be calculated: the direct radiant heat of sun, the albedo of the environment, and the equivalent radiant temperature of the environment. These data, combined properly with the air temperature and velocity, will give the operative temperature which is a measure of the thermal stress of the environment.

Viscosity of muscle protoplasm. PETER RIESER (introduced by L. V. HEILBRUNN). *Zoological Lab, Univ of Pennsylvania, Philadelphia, Penna.* Small oil drops were microinjected into muscle fibers from the adductor magnus of the frog, and the rise of the drops through the protoplasm was observed in a horizontal microscope. The protoplasmic viscosity was determined from Stokes' law. An average value of 29 centipoises was obtained. Some higher values were interpreted as representing cases where a slight degree of injury had occurred. Visible clots always caused stoppage of the

movement of the drops Oil drops were able to move only in one direction through the fibers No movement across the fibers was ever observed Moreover, no movement of the drops could be noted in moribund fibers in which longitudinal fibrillar elements had become visible These facts, as well as the ovoid shape of the drops, suggest the existence of some longitudinal structural arrangement within the fibers Microinjection of long stretches of fibers with oil or air always showed that a peripheral region directly within the sarcolemma could never be displaced by these substances This outer region had a thickness of approximately 10μ By microinjecting aqueous solutions it was possible to push the protoplasm ahead through the fibers In every instance where such a flow occurred, there was a peripheral region of approximately the same thickness as noted above, and this peripheral region did not flow The outer region thus appears to be similar to the gel-like cortex of other types of cells

Analysis of ventilation-perfusion relationships in the lungs R L RILEY and A CURNAND *Dept of Medicine, Columbia Univ College of Physicians and Surgeons, New York City* The composition of alveolar air and of the blood leaving the alveolar capillaries in any part of the lung depends upon the ventilation-perfusion ratio, and conversely, analysis of the ventilation-perfusion ratio requires that the composition of the alveolar air be known Since the alveolar air differs in different parts of the lungs, especially in diseased states, calculations are facilitated by the use of an 'ideal' value, defined as the one and only value for the composition of alveolar air which satisfies both the blood R Q and gas R Q equations, assuming perfect equilibrium between the blood and gas leaving each alveolus This is the only value for alveolar air which could exist homogeneously throughout all functioning alveoli and still be compatible with the quantitative aspects of gas exchange which actually exist in a given subject The concept of 'ideal' alveolar air makes possible the calculation of a value for 'dead space' which includes a contribution from alveoli which are well ventilated but poorly perfused (high V_a/P ratio) It also makes possible the calculation of a value for 'venous admixture' which includes a contribution from alveoli which are well perfused but poorly ventilated (low V_a/P ratio) These relationships have been studied quantitatively in normal individuals and in patients with chronic pulmonary disease

Measurements of heart output with the electrokymograph GORDON C RING, M J OPPENHEIMER and MIRIAM BALABAN (by invitation) *Temple Univ Medical School, Philadelphia, Penna* Measurement of the stroke volume of the heart by means of the roentgenkymograph (*Am J Physiol* 126:741, 1939) has never been widely used probably because the heart borders are so poorly defined The

use of x-rays with the electrokymograph (EKY) appears to offer a more satisfactory method because the movements of the heart borders can be amplified and the records very accurately measured To test whether such records are suitable for calculating heart output, we have compared the results using our method with those obtained from ballistocardiograms (*J Clin Invest* 26:1, 1947) simultaneously recorded It was found that the measurement of heart output by means of the E K Y gives results comparable with those obtained by the ballistocardiograph Only 5 of 30 records on normal medical students and nurses showed differences between the two methods of more than 20% Since the cardiac output measured by ballistic methods checks the Fick no closer than this, our procedure may be as good as or better than the ballistocardiograph It also provides other valuable information With the subject lying on a ballistocardiograph table, the head of the electrokymograph is so placed that its fluorescent screen which is 3 cm in diameter is judged to be over the middle of the ventricular x-ray shadow Changes in intensity of the fluorescent light are signaled by a current from a 931 A tube which activates a string galvanometer These records are calibrated by passing a piece of pressed wood into and out of the x-ray beam The formula used in the calculations is $\text{Stroke} = 10.55 (T^2 \text{ diast} - T^2 \text{ syst})$ where T is the dorso-ventral thickness in centimeters

Electrograms of contracting actomyosin threads JANE SANDS ROBB and SAMUEL MALLOV *Dept of Pharmacology, Syracuse Univ College of Medicine, Syracuse, N Y* Electrodes penetrate a drop of solution into which threads of actomyosin are drawn Connections by way of Offner amplifiers allow records to be made either with an ink writer, a research electrocardiograph or a Dumont oscilloscope During control procedures many possible sources of extraneous currents were investigated, eliminated whenever possible, and at least are recognized when unavoidably present Under controlled conditions potentials appearing when ATP is added to salt solution die away quickly leaving a steady base line If ATP is made to disintegrate (heat or acid) potentials last far longer No potential waves are recorded from a quiescent actomyosin thread When a thread is activated potentials do appear which continue until full contraction is reached, after which time the base line is again steady If another thread is drawn into, the same drop contraction and further potential differences occur The intervening steady base line favors a theory associating these potential changes with thread activity The form of the recorded waves varies with the setting of the instrument Multiple channels allow simultaneous recording with varied settings If high frequencies are favored bursts of fine peaks appear If the setting is as for electro-

cardiography, the characteristic record consists of a series of slow monophasic waves each of which seems to precede a local contraction. Amplitude varies with the nearness and orientation of the thread to electrodes but less obviously to thread diameter.

Effect of some xanthine derivatives on gastric secretion C R ROBERTSON (by invitation) and A C ILL *Dept of Clinical Science, Univ of Illinois College of Medicine, Chicago, Ill*. Some xanthine derivatives have been reported to show an anti-histamine effect on smooth muscle in the cat. This led us to investigate their effects on gastric secretion. In dogs with pouches of the entire stomach 0.0125 mg histamine dihydrochloride was given subcutaneously every 10 minutes. When the secretory rate became relatively constant (2 to 3 hours) the drug to be tested was injected intravenously and the histamine injections were continued. Five tenths gm theophylline was found to potentiate the histamine-stimulated acid secretion (6 tests). The difference was statistically significant. When the theophylline was given alone (without histamine), 3 tests, it did not stimulate gastric secretion. Krasnow in our laboratory has shown that theophylline given alone (intragastrically) in man, will stimulate gastric secretion. Xanthine (0.2 gm—six tests) and theobromine (0.5 gm—7 tests) increased the average secretory response to histamine but the differences were not statistically significant. Caffeine has been shown to stimulate gastric acid secretion in cat and man but not in the dog. It also potentiates histamine-induced gastric secretion in cat and man. We have investigated the effect of caffeine on histamine-induced gastric secretion in the dog and found that 0.5 g (8 tests) potentiated the secretion (statistically significant). These results show that certain xanthine derivatives which, when given alone, fail to stimulate gastric secretion in the dog are able to augment the response to histamine.

Effect of epinephrine on the water and electrolyte composition of cardiac muscle WM A B ROBERTSON and PIERCE PEYER (introduced by F J SICHEL) *Division of Exptl Medicine and Dept of Biochemistry Univ of Vermont, College of Medicine, Burlington Vt*. The hearts of anesthetized cats were removed at intervals up to 11 minutes after intravenous injection of 5 to 500 μ g of epinephrine per kilo, and were analyzed to determine whether changes in concentration of water and electrolytes in cellular and extracellular phases had occurred. In all cases an increase in extracellular water as derived from chloride concentration according to the theory of Boyle and Conway (*J Physiol* 100:1 1941) was found. Direct confirmation of this extracellular increase was obtained by measuring changes in sucrose space. Increases in cell water were also found.

EPINEPHRINE	TIME	(H ₂ O) _E	(H ₂ O) _{SUCROSE}	(H ₂ O) _C
μ g/kg	min	m/kg of dry muscle		
0		1340		3130
5	4	1590		3020
5	11	1390		3170
50	2	1860		3410
50	4	1800		3300
50	11	1690		3260
500	6	2040		3810
0 (sucrose)		1100	1010	3170
100 (sucrose)	4	1610	1400	3220

An increased sodium and decreased potassium concentration in the cell water was observed only after injection of 500 μ g of epinephrine per kilo.

Factors correlated with resistance to decompression sickness TRUE W ROBINSON *Yellow Springs, Ohio*. In studies made on the resistance to decompression sickness of 18 men in a series of 12 altitude chamber flights, a variety of physiological data was obtained which has now been analyzed for factors which might correlate with this resistance. This data included pre-selection tests for the human centrifuge, accelerational or G-tolerance measurements, basal metabolism determinations, and studies on physiological responses to rest and different kinds of exercise both on the ground and at altitude. In all of the foregoing procedures, information on heart rate, blood pressure, oxygen consumption, and respiratory rate was obtained, as well as personal data regarding weight, height, surface area, anthropometric type, use of alcohol and tobacco, sleeping habits etc. Studies of these various factors indicate that most of these elements show little or no correlation with decompression sickness tolerance (as determined by average time at altitude for 8 or 12 flights). Low correlation is shown by the resting diastolic pressure and the systolic, diastolic and pulse pressures, pulse rate and respiratory rate obtained one minute after a step up exercise used as pretreatment before a chamber flight. Personal habits and characteristics also do not show a good correlation. There is a fair correlation with the resting pulse rate and a good correlation with resting systolic blood pressure and respiratory rate.

Blood pressure changes produced by local thermal stimulation of the brain S ROBBAND, L TAYLOR (by invitation) and D FRANKSON (by invitation) *Cardiovascular Dept., Medical Research Institute Michael Reese Hospital Chicago, Ill*. The effect of various degrees of thermal stimulation of the brain on the blood pressure response was tested in 248 trials on 59 turtles. After removing the calvarium a silver wire attached to a water reservoir was inserted into the brain. Various regions were explored for temperature sensitivity as indicated by blood pressure changes.

With large temperature differences (15°C) between brain and wire, consistent responses were not seen when the wire was in the olfactory lobe, optic lobe, in the medulla or laterally in the cerebral hemispheres. When the wire was in the midline between the cerebral hemispheres, a consistent increase in blood pressure was seen with warming by means of the wire, and a decrease with cooling. With small temperature differences (5°C) between the wire and the brain, the blood pressure response was slow and less marked.

Direct determination of gas tensions by blood
ALBERT ROOS and H. BLACK (introduced by H. L. WHITE) *Depts of Surgery and Physiology, Washington Univ School of Medicine, St. Louis, Mo.* A study was made of conditions affecting the accuracy of direct *in vitro* determinations of gas tensions in blood. Human blood with heparin and NaF added was equilibrated for 30–60 minutes at 37°C in a large flask containing known gas mixtures. It was then anaerobically transferred to a small tonometer containing mercury and a small gas bubble, which was mechanically agitated at 37°C . The total bubble tension was determined with a special capillary manometer, keeping the bubble volume constant, after which the bubble was analyzed in a Scholander apparatus. Calculations showed that, if complete equilibration were accomplished with the bubble volumes and gas mixtures used, the blood oxygen tension should not change by more than 1–4 mm Hg. However, although the oxygen tensions of blood and bubble approached each other rapidly during the first 10 minutes of equilibration, the exchange slowed down considerably between 10 and 15 minutes in such a way that the bubble tension after 15 minutes still differed from that of the blood by 5–10 mm Hg, when the initial blood-bubble difference was 10–20 mm Hg. Satisfactory results were obtained only when the initial bubble tension was within 5 mm Hg of the blood tension. In bloods with oxygen tensions of 100 mm Hg and above the tension values fell progressively on repeated determinations, which could not be ascribed to the action of mercury amalgam or stopcock lubricant. This fall was less marked at lower tensions.

Effect of immersion hypothermia on cardiac output
FELIX R. ROSENHAIN (by invitation) and K. E. PENROD *Dept of Physiology, Boston Univ School of Medicine, Boston, Mass.* Cardiac output has been determined by the Fick method in dogs immersed in cold water. Observations were made before immersion and at rectal temperatures of 35° , 30° , 25° and, where spontaneous breathing continued, 20°C . In 3 experiments early signs of shock developed as evidenced by a precipitous fall in blood pressure and O_2 consumption. These were eliminated from the aver-

ages. Data from the other 9 experiments appeared to indicate 1) between 35° and 25°C rectal temperature the average cardiac output, pulse and O_2 consumption fell approximately linearly, 2) a peak in the O_2 consumption curve at 35°C , associated with shivering, was reflected in the cardiac output curve, but not in the pulse curve, 3) individual variation in stroke volume was considerable but in most instances there occurred a slight increase with decreasing body temperature.

Histamine as a possible mediator for cutaneous pain
SOL ROY ROSENTHAL *Univ of Illinois College of Medicine, Chicago, Ill.* Thin slices of freshly obtained human skin were studied *in vitro* by a method described by Rosenthal and Mennard. Such stimuli as punching, pricking, electrical and burning yielded a profusate which when reinjected into the skin of the donors elicited pain responses, wheal, and flare directly proportional to the degree of stimulus and corresponded closely to histamine injections. The anti-histamine drug N-dimethyl-amino-2-propyl-1-thiodiphenylamine (RP3277) when administered to humans in 40 to 80 mg single doses resulted after 3 to 4 hours in a diminution of the responses to pain as well as wheal and flare to histamine.

Measurement of sympathetic denervation in man by sweating patterns after sympathectomy.
GRACE M. ROTH and WINCHELL MCK. CRAIG (by invitation) *Section on Clinical Physiology and Section on Neurologic Surgery, Mayo Clinic, Rochester, Minn.* Over a 10-year period, 1937 sweating tests were carried out by the cobalt chloride method on 1022 patients 8 to 14 days after surgical interruption of sympathetic fibers in treatment of hypertension or peripheral vascular disease. The sweating test immediately after such operations on the sympathetic nervous system demonstrated irregular patterns of sweating in a large group of patients. This observation indicates incomplete denervation of the region which the operation was expected to denervate rather than regeneration. This incompleteness of denervation probably can be explained by the unpredictable lack of uniformity of the distribution of the sympathetic nerves. Tests five to six months after operation in some instances demonstrated that the region of anhidrosis was less extensive than it had been immediately after operation. After this interval of six months, however, the region of anhidrosis remained practically the same for sixteen to twenty years.

In-vitro histamine release from blood cells of sensitized rabbits—relationship to blood-coagulation mechanisms
L. W. ROTH, FLOYD C. MCINTIRE (by invitation), and R. K. RICHARDS *Depts of Pharmacology and Biochemistry, Abbott Research Laboratories, North Chicago, Ill.* The *in-vitro* addition of antigen to whole blood of

sensitized rabbits causes histamine to be released from the cells into the plasma (Katz, *Science* 91 221, 1940) It is well known that coagulation of blood also causes the release of histamine from the blood cells In a study of the mechanism of the 'anaphylactic' *in-vitro* histamine release from rabbit blood cells, the possibility of participation by various components of the blood coagulation system must be considered Our investigations indicate that thrombin, prothrombin and at least part of the 'thromboplastin complex' probably are not involved in the *in-vitro* 'anaphylactic' histamine release because 1) the quantity of heparin required to inhibit only partially the histamine release by antigen is many times the amount required to prevent blood coagulation under identical conditions, 2) extreme prolongation of the blood-clotting time of sensitized rabbits by dicumarol treatment does not impair the 'anaphylactic' histamine release, 3) soybean trypsin inhibitor (Kunitz, *J Gen Physiol* 30 291, 1947), which is a potent 'anti-thromboplastin' (MacFarlane, *J Physiol* 106 104, 1947), fails to inhibit the histamine release by antigen However, a similarity between the mechanism of histamine release by antigen and the blood-coagulation mechanism is suggested by the fact that the histamine release by antigen is completely inhibited by 0.06 molar sodium oxalate or 0.06 molar sodium citrate and is markedly inhibited by 0.3 molar magnesium chloride or 0.2 molar calcium chloride The citrate inhibition is only partially reversed by recalcification

An indication that the ovulating hormone release inducing action of progesterone is an indirect one IRVING ROTHCHILD (introduced by D C SMITH) *Bureau Animal Industry, Beltsville, Md* Progesterone induces ovulation in the intact domestic hen, but is completely ineffective in the absence of the pituitary (Rothchild and Fraps, *Endocrinology* 44 1949) In order to determine whether it acted directly on the pituitary, 0.012-0.018 cc of either 10.0 mg/cc or 1.0 mg/cc progesterone in propylene glycol was applied to the surface of the pituitary, exposed as for hypophysectomy, in birds carrying a mature follicle, and either left in the drill hole or removed after 1.0 or 3.0 minutes Out of 10 birds treated with 10.0 mg/cc progesterone (not removed) 6 ovulated, but only 5 out of 17 treated for 3 minutes, and only 3 out of 8 for one minute ovulated No birds ovulated following treatment with the 1.0 mg/cc progesterone for 3 minutes Practically the same results were obtained when the progesterone (10.0 mg/cc) was applied either to the partially drilled, or completely undrilled, bone over the pituitary Two out of 3 birds in which the progesterone was left, and 2 out of 10 treated for 3 minutes ovulated These findings indicated a relation between pas-

sage of progesterone through a systemic pathway and effectiveness in inducing hormone release from the pituitary Additional weight to this possibility was given by the fact that 7 out of 10 birds ovulated following application of 3 drops of the 10.0 mg/cc progesterone to the thigh muscle for only 3 minutes

Some factors influencing the exchange of ions across nerve membranes MORTIMER A ROTHENBERG (introduced by DAVID NACHMANSOHN) *Dept of Neurology, College of Physicians and Surgeons, Columbia Univ, New York City* The ion exchanges across the nerve membrane have been measured by direct determination of K^{42} and Na^{24} penetration into the axoplasm of the giant axon of Squid Previous results indicate that at rest the ionic composition in these nerves is in dynamic and not static equilibrium with that of their outer environments Employing the same technique, several physical and chemical factors influencing this equilibrium have now been studied Changes in temperature showed a small Q_{10} supporting the assumption that at rest there are no important chemical reactions involved other than a Donnan equilibrium Electrical activity markedly increased the rate of Na^{24} penetration Anticholinesterases, in general, gave an overall result similar to that obtained with nerve activity Exposure to diisopropyl fluorophosphate increased the rate of Na^{24} penetration by about 50% and decreased the K^{42} penetration by about 35% The increase in Na^{24} penetration produced by eserine was slightly smaller Unlike the anticholinesterases, cocaine had a very small effect on the membrane permeability Exposure of nerves to high doses of X-rays produced a marked increase in Na^{24} penetration and a marked decrease in K^{42} penetration in normally conducting nerves This observation indicates an early phase of possible damage to the intact nerve cell by irradiation in spite of apparently normal function

Action of thyroxine on protein metabolism J RUPP (by invitation), K E PASCHKERS and A CANTAROW *Jefferson Medical College, Philadelphia, Penna* Thyroid hormone is usually looked upon as stimulating protein metabolism However, certain well-known facts, such as the dwarfed stature of cretins and the resumption of growth following thyroid therapy, indicate that thyroid hormone may exert a protein anabolic effect The following experiments were performed in order to determine under what circumstances thyroid hormone would be a 'protein anabolizer' All experiments were performed on force fed rats receiving a constant food intake Thyrotoxicity resulted in N loss, this was observed as a N balance effect, thereby precluding unspecific negative N balance due to proprotein catabolism Daily injection of 5 to 10 mg of thyroxine (pharmaceutical grade) was followed by N retention

bolic effect) in the thyroidectomized rat, but had no effect in the intact rat. Large doses (50–100 μ g) caused N-loss (catabolic effect) both in intact and in thyroidectomized rats. In hypophysectomized rats neither the anabolic effect of small, physiological amounts, nor the catabolic effect of large doses of thyroxine could be obtained. Pituitary function appears to be necessary for the effect of thyroid hormone on protein metabolism in fed rats. Experiments are under way to investigate further the interaction of thyroid and pituitary in protein metabolism.

Cinéf luorography of the normal human heart, teaching application (motion picture) R. F. RUSHMER (introduced by T. C. RUCH) *Dept. of Physiology and Biophysics, Univ. of Washington, Seattle, Wash.* A training film demonstrating the anatomical relations of the normal cardiac silhouette in the postero-anterior, right anterior oblique, and left anterior oblique positions is presented. Heart models, teleroentgenograms and cinéf luorograms are arranged in sequence to facilitate visualizing the fluoroscopic appearance of the heart.

Kinetics of cholinesterase of erythrocytes in pernicious and other anemias JEAN CAPTAIN SABINE (introduced by CHARLES I. WRIGHT) *Experimental Biology and Medicine Inst., National Insts. of Health, Bethesda, Md.* Cholinesterase activity was determined manometrically over a wide range of concentrations of acetyl choline in 4 cases of pernicious anemia and 5 cases of anemia from hemorrhage. The data were subjected to the analysis previously made of normal human erythrocytes (*J. Pharm. & Exper. Therap.* 93:230, 1948). The theoretical limiting velocity, V , expressed per unit volume of red blood cells (or per cell), was increased by a factor of 1.5 to 2.5 in anemia from hemorrhage and in pernicious anemia in relapse and during treatment. The values of the apparent dissociation constants K_1 and K_2 of the active and inactive enzyme-substrate complexes were normal in anemia from hemorrhage. In pernicious anemia in relapse the experimental value of K_1 was increased about 3-fold and that of K_2 decreased by the same amount. During three weeks or more of treatment the experimental values of these constants gradually shifted to normal. This shift is probably not attributable to a direct action of the therapeutic agent on the enzyme-substrate system. The high value of V was maintained until the red count and hematocrit approached the normal levels and then fell off. Discussion will include the interpretation of the changes found in pernicious anemia, interpretation of previous findings in pernicious anemia in the light of the present investigation, and a correlation which has been found between clinical condition of severely anemic patients in general

and increased enzymic concentration in the red cells.

Analytic study of effects of various patterns of X irradiation on survival GEORGE A. SACHER, JOHN SACKIS (by invitation) and AUSTIN M. BRUES *Biology Division, Argonne National Lab., Chicago, Ill.* Sixteen hundred female CF-1 mice were treated with 250 kv total-body X radiation according to the following dosage patterns: 400 r in a single dosage, or in 10 or 40 daily treatments; 800 r in 10 or 40 treatments; 1200 r in 40 treatments; 5 r daily throughout life; 800 r in 40 treatments superimposed upon 5 r daily throughout life. There were 1400 control mice. Gross mortality rates have been computed as a function of time, in addition to rates associated with certain prominent types of pathologic change. As a general rule, all patterns of treatment increase the incidence of all types of pathology at all ages. The effect of radiation on rates of mortality is best expressed by means of the Gompertzian diagram (logarithm of rate of mortality against time). In this form, all categories of pathology in control animals show a linear increase with age, as is well known in the case of many human diseases. A dosage administered to young adult mice within a short interval (weeks) displaces these lines upward by a constant amount. The incidence of lymphoid tumors is phasic and constitutes an exception to this rule. The effect of daily small exposures throughout life combined with a heavy exposure early in life is discussed in terms of gross mortality excluding lymphoid tumors. To a first approximation, the results are additive on the Gompertzian diagram. The results indicate lines along which a calculus of radiation mortality may be developed for arbitrary time patterns of exposure.

Turnover rates of acid-soluble phosphorus compounds of liver JACOB SACKS and SHEPHERD STIGMAN (by invitation) *Biology Dept., Brookhaven National Lab., Upton, L. I., N. Y.* Methods have been worked out for the separation of various acid-soluble phosphorus compounds of liver and applied to tracer experiments on rats in the post-absorptive state. The time-course of the P^{32} levels of plasma inorganic-P and the organic-P compounds of liver has been studied. The highest P^{32} level in the plasma P was found $\frac{1}{2}$ hour after subcutaneous injection of the tracer phosphate. The level fell rapidly for the next 1.5 hours, and then progressively more slowly. The maximum P^{32} levels in the P compounds of liver were generally found 1.5 hours after injection of the tracer. The labile P of ATP and ADP showed a higher turnover rate than any other organic P compound studied. The time-course of the P^{32} content of the intracellular inorganic P of liver was found to run parallel with that of the labile P of ATP and ADP,

and to show no such relation to that of plasma P^{32} . This indicates that the former compounds serve as the principal means of transferring inorganic phosphate from the extracellular phase to the interior of the liver cell. Data on the relative turnover rates of ATP-ADP and of glucose-1- and glucose 6- phosphates are presented.

Interplay of light and heat in bleaching rhodopsin ROBERT C. C. ST. GEORGE (introduced by GEORGE WALD) *Biological Lab of Harvard Univ., Cambridge, Mass.* The pigment of rod vision, rhodopsin, is destroyed by heat with an apparent activation energy for this process of about 45,000 cal/mol at pH 5-9 (Lythgoe and Quilliam). At lower temperatures it bleaches in white light by a process independent of the temperature (Hecht). In the present experiments an attempt was made to study the transition between these situations by irradiating rhodopsin with red light, quanta of which are in themselves too small to supply the entire energy of activation. It was found that at pH 7 the bleaching of rhodopsin by light has become appreciably temperature-dependent at 650 $m\mu$. As the wave length is increased further the temperature coefficient of bleaching continues to rise. The apparent thermal energies of activation found at these long wave lengths, added to the energy content of the light itself, appears to approximate 45,000 cal/mol. That is, when less than 45,000 cal are supplied by the absorbed light quanta, the deficit in activation energy is made up from the internal energy of the molecules themselves. About 45,000 cal appear to be required for bleaching rhodopsin, whether supplied as light or heat or as a combination of both. Measurements could not be made at wave lengths longer than 715 $m\mu$, due to the very low absorption of rhodopsin in this region. These observations suggest however that at 1050 $m\mu$, where rod vision still persists (Griffin, Hubbard and Wald) and where the energy content of the radiation is only about 27,000 cal/mol of quanta, about 18,000 cal probably come from the internal energy of the rhodopsin molecule.

Phosphate turnover in the mammalian nervous system A. J. SAMUELS (by invitation), L. L. BOYANSKY (by invitation), B. LIBET, R. W. GIRARD, M. BRIST (by invitation) *Dept. of Physiology, Univ. of Chicago, Chicago, Ill.* Radio active phosphorus 300 microcuries as $NaH^{32}PO_4$ was injected intraperitoneally into guinea pigs in a single dose or spread over 2 weeks in daily doses. Animals were killed at intervals from 6 hours to a week over a 5 week span and the brain, spinal cord and sciatic nerves analyzed for acid soluble phospholipid, phosphoprotein and nucleoprotein phosphorus following Schneider and actively measured

P in plasma or tissue at a given time, indicate rates of penetration or turnover. The uptake of phosphate by nervous tissue from plasma is slow, R (for tissue acid-soluble P against plasma) reaching unity (an arbitrary value) in about 22 days for brain, 30 days for nerve and 36 days for spinal cord. Turnover rates were also slow. Bracketed numbers below give average mg % P of tissue fraction indicated R (against tissue acid-soluble P) for phospholipid reaches unity in 32 days in brain (166) and spinal cord (341), 37 days in nerve (254), for phosphoprotein, 30 days in spinal cord (26), 36 days in brain (21), 40 plus days in nerve (26), for nucleoprotein, 16 days in cord (16), 40 plus days in brain (24) and nerve (17). R for phosphoprotein rises faster in proximal segments of nerve than in distal ones. Our evidence favors the view that protein moves continuously from cord to periphery at a rate of about 3 mm/day. A mathematical method has been developed for describing certain simple cases of the uptake and leakage of radioactive materials by tissues.

Hormones and hormone-like substances in the treatment of (experimental) peptic ulcer DAVID J. SANDWEISS and HARRY C. SALTZSTEIN (by invitation) *Harper Hospital and Dept. of Surgery, Wayne Univ. College of Medicine, Detroit, Mich.* This report deals with the results obtained from 37 control (untreated) Mann-Williamson dogs and 12 other series of similarly operated animals treated with various hormones and hormone-like substances, totaling in all 282 animals. All preparations were administered parenterally. In addition, enterogastrone and the anterior pituitary-like hormone (Ant S) were also administered orally in two other series of Mann-Williamson dogs. The average post-operative survival time of the control series was 63 days. All control animals died of ulcer. The longest survival time was 135 days. Eight % of the ulcers showed microscopic evidence of healing (epithelization). Results in the treated series of animals are as follows: 1) The extracts obtained from human urine (pregnant women, normal women and normal men) were of definite benefit. Extracts obtained from the urine of ulcer patients had some, but very much less activity. Pregnancy urine extract administered orally did not prolong the life of the animals but it did stimulate epithelization in a significant number of the ulcers. 2) The gonadotropic hormone from pregnant mare's serum (Gonadotropin) was definitely beneficial. 3) Progesterone (Proluton) showed some beneficial effect in that it definitely stimulated epithelization. 4) Estrogen (Thelin) was of no value. 5) The posterior pituitary extract (Pituitrin) produced little effect, except that of Pituitrin

the enterogastrone concentrate we employed had no beneficial effect

Concerning relation of the pituitary gland to enterogastrone and urogastrone D J SANDWEISS, J KAULBERSZ, T L PATTERSON and H C SALTZSTEIN (by invitation) *Depts of Physiology and Surgery, Wayne Univ College of Med and Harper Hosp, Detroit, Mich* Enterogastrone and urogastrone were prepared from the intestines and urine of normal dogs and hypophysectomized dogs by the usual methods. The procedures were identical for both series of experiments. The effect of these extracts on gastric secretion was studied by the double-histamine tests on fistula and Heidenhain pouch dogs. The extracts were always administered during the first period of the test. Approximately an equal degree of inhibition of gastric secretion was observed with both normal enterogastrone (12 exper, 4 dogs, dose 50 mg) and hypophysectomized enterogastrone (8 exper, 3 dogs, av dose 23 mg). Normal urogastrone (32 exper, 7 dogs, dose 1 to 2 mg) and hypophysectomized urogastrone (16 exper, 5 dogs, dose 3-10 mg) also produced a comparable degree of inhibition in response to histamine as an immediate effect. However, while no after-effect could be detected in the experiments with normal urogastrone a more striking inhibitory effect in comparison with the immediate effect was noted 5 to 9 hr after administration of the hypophysectomized urogastrone. These effects were found to be statistically significant. It appears, therefore, that hypophysectomy does not significantly alter enterogastrone formation. However, the characteristics of urinary extracts are changed by hypophysectomy in a very striking manner as noted above and as described more fully in another presentation (see Patterson *et al*)

The effect of spinal anesthesia on circulating blood volume S J SARNOFF, E S BUCKLEY, JR, J L WHITTENBERGER and J G GIBSON, II (introduced by W H FORBES) *Dept of Physiology, Harvard School of Public Health, and Dept of Medicine, Harvard Medical School, Boston, Mass* In preliminary clinical studies it was demonstrated that spinal anesthesia benefited the patient in pulmonary edema. Subsequent clinical studies confirmed these early observations. It was thought that one of the associated phenomena that accompanies spinal anesthesia might be a reduction in the volume of blood in the pulmonary vascular bed. As a result of plethysmographic and oncometric studies in which the volume of the extremities and the viscera is found to be increased during spinal anesthesia, it is assumed that the volume of blood in the systemic circuit is increased during this type of sympathetic block. It was decided therefore that if, under spinal anesthesia, the total blood volume remained unchanged, the

volume of blood in the pulmonary bed should be diminished. Total circulating plasma volumes were determined by the T-1824 method and red cell volumes were determined by the radioactive red cell technique just before spinal anesthesia and 30 and 60 minutes after it was started. Spinal anesthesia was administered through an indwelling ureteral catheter previously introduced through the atlanto-occipital membrane. Spinal anesthesia adequate to obliterate the tendon reflexes and cause lower intercostal paralysis was maintained by intermittent injections of 2% procaine hydrochloride. The total circulating plasma volume was found to be unchanged in 6 dogs under the influence of spinal anesthesia.

Effects on the circulation of electrophrenic respiration and positive pressure breathing during high spinal anesthesia STANLEY J SARNOFF, JAMES V MALONEY, JR and JAMES L WHITTENBERGER (introduced by WILLIAM H FORBES) *Dept of Physiology, Harvard School of Public Health, Boston, Mass* It was demonstrated that intermittent positive pressure depresses the circulation of the dog when spinal anesthesia is carried high enough to cause respiratory paralysis. Under these conditions, the sympathetic vasoconstrictor outflow is totally blocked and increased intrathoracic pressure, even though it be intermittent, retards the return of blood to the heart. Proportionality was established between the pressure used during insufflation and the depression of the blood pressure. Electrophrenic respiration was accomplished by applying a cyclically undulating potential to one or both phrenic nerves so that the diaphragm was made to contract and relax in a smooth manner. When electrophrenic respiration was applied, the effect was a stimulation of the circulation in the same animals whose blood pressure was depressed by positive pressure breathing. Changing from positive pressure breathing to electrophrenic respiration in the dog under total spinal anesthesia widens the pulse pressure and elevates the mean arterial blood pressure between 25 and 40 mm Hg. Changing from electrophrenic respiration to positive pressure breathing depresses the blood pressure by the same amount. Under the conditions of the experiment, in which there is a total sympathetic block, elevations or depressions of blood pressure are taken to reflect similar qualitative changes in cardiac output.

Effect of pitressin and desoxycorticosterone in low dosage on excretion of water and sodium OTTO W SARTORIUS and KATHLEEN ROBERTS (introduced by R F PITTS) *Dept of Physiology, Syracuse Univ College of Medicine, Syracuse, N Y* In a series of experiments on 3 normal female dogs in which a standard 2-hr urine flow curve was obtained following the oral administration of 40 cc of water/kg, the intravenous injection of 0.8 mU of pitressin/kg produced an antidiuresis of

30-45 minutes duration. The antidiuresis so obtained was substantially modified by intravenous injection of small doses of homogenized desoxycorticosterone in sesame oil and water, administered 15 minutes prior to the pitressin and at the same time as the water load. All experiments were performed under similar fasting conditions with all control urine flows ranging between 0.2 and 0.5 cc/min. Urine collections were obtained by catheter at 15-minute intervals according to standard technique. Sodium excretion, determined in all experiments, and within limits of 5 and 25 μ Eq/min in the control periods, decreased to about one-third during water diuresis returning to the original level 2-3 hrs later. Pitressin in a dosage of 0.8 mU/kg produced a 10-fold increase in sodium excretion with the peak excretion occurring 45 minutes after its administration. By 90 minutes, sodium excretion had fallen below the control water diuresis level. The effect of pitressin on sodium excretion was modified or abolished by 10 to 100 γ /kg of desoxycorticosterone. It is probable that pitressin and desoxycorticosterone are antagonistic in physiological dosage both as to water excretion and sodium excretion.

DFP and reflex activity in salamander larvae
CHARLES H. SAWYER (introduced by J. E. MARKEE) *Dept of Anatomy, Duke Univ., Durham, N. C.* Di-isopropyl fluorophosphate (DFP) which irreversibly inhibits cholinesterase (ChE), also severely impedes reflex activity in salamander larvae (Boell, 1946). The present experiments were devised to determine what degree of correlation existed between the amount of enzyme inhibition and the extent of interference with reflex motility. Fifty larvae of *Amblystoma punctatum* (Harrison's stage 46) were stimulated individually with a hair 60 times at one-second intervals and the number of each animal's reflex responses was recorded. Twenty-five larvae were then immersed in solutions of DFP (5.5×10^{-5} M) for intervals varying from 5 minutes to several hours. At the end of its DFP period each experimental larva was stimulated and scored as above, washed, and assayed for ChE activity. Controls were clutch-mates of the DFP animals and reared under identical conditions but for the anti-cholinesterase; each control had a reflex-response score closely similar to that of its experimental counterpart prior to the latter's immersion in DFP. A high degree of positive correlation was found to exist between the residual reflex capacity (expressed as percentage of the pre-inhibition response score, range, 0-100%) and the residual ChE activity (expressed as percentage of the control's enzyme content, range, 0-99%). The coefficient of correlation, $r = 0.93$. It is concluded that the effect of DFP on reflex motility is attributable entirely to inhibition of ChE and that a

quantitative relationship exists between reflex capacity, during a given developmental stage, and the amount of cholinesterase available to the neuromuscular apparatus.

Quantitative estimation of capillary passage of fluorescein in rabbit skin
ALFRED A. SCHILLER *Dept of Physiology, Univ of Ill., College of Medicine, Chicago, Ill.* The fluorescence of minute concentrations of sodium fluorescein in the skin can be measured photometrically in long wave UV. The time and intensity relations of the appearance and disappearance of the dye from wheals made with vasoactive drugs have been found to be sufficiently graded to establish quantitative response patterns characteristic of the drug action at a given concentration. Serial dilutions of histamine phosphate, epinephrine HCl, and histamine + epinephrine dissolved in 0.9% NaCl solution were used to make the wheals in the abdominal skin of the rabbit. Controls were performed with the solvent alone. Fluorescein was either injected intravenously or incorporated in the wheal solution (0.1 ml intradermally). The results were as follows: the intensity of fluorescence increased and the disappearance rate of the dye decreased with increasing concentration of histamine over a range of 10^{-3} to 10^{-7} . Epinephrine concentrations from 10^{-3} to 10^{-6} prevented fluorescence in the wheals. The diameters of the non-fluorescent wheals were increased with drug concentration. By using various ratios of simultaneously injected mixtures of histamine and epinephrine it was found that histamine 10^{-3} + epinephrine 10^{-5} produced the same response as the saline control. This method may be of use for the study of capillary permeability when correlated with data supplied by other techniques.

Reduced evaporative water loss from the lungs of certain desert mammals
BODIL SCHMIDT-NIELSEN (introduced by LAURENCE IRVING) *Dept of Physiology, Stanford Univ., and Arctic Research Lab., Stanford, Calif.* It was shown that desert rodents of the family Heteromyidae are able to economize with water by excreting a highly concentrated urine. The question arises if they have other mechanisms for saving water. The evaporation from the animal was determined simultaneously with the oxygen uptake. When the water evaporated is calculated on the basis of the simultaneous oxygen consumption it is found that the water evaporation is approximately one half of what it is in other rodents of the same size (white rat and white mouse). The water evaporation from the Heteromyids breathing completely dry air is on the average 0.45 mg water/ml oxygen taken up. The amount of water formed by metabolism of food in the body is approximately 0.65 mg water/ml oxygen consumed. Therefore water is gained in the metabolism, even when dry air is

inspired (See also abstract by Knut Schmidt-Nielsen)

Efficiency of the excretory system in desert mammals KNUT SCHMIDT-NIELSEN (introduced by LAURENCE IRVING) *Dept of Physiology, Stanford Univ, and Arctic Research Lab, Stanford, Calif* The critical factor in the water metabolism of mammals living in deserts is that the expense of water required for urine, saturation of the expiratory air, and heat regulation cannot easily be covered by the limited supply of water available. Reduction of any of these three main sources of water loss will be of advantage to the organism. Desert rodents of the family Heteromyidae live without access to drinking water. We found that their renal excretory system is well adapted to conserve water by a very concentrated urine (1 normal salt and 4 molar urea). To prove that high urine concentrations can be maintained and are not only occasional, we gave sea water (ca. 0.58N) for drinking. In view of the capacity for concentrating urine it might be expected that the animals would tolerate sea water, which other mammals cannot because of its large salt content. It was found that the Heteromyids do tolerate drinking sea water, and are even able to excrete simultaneously excessive amounts of non-electrolytes (urea). (See also abstract by Bodil Schmidt-Nielsen)

'Impedance' variation in the nerve membrane during passage of the natural action potential OTTO H. SCHMITT *Dept of Zoology and Physics, Univ of Minnesota, Minneapolis, Minn* Extension of a previously described method of analysis permits direct and semi-quantitative calculation of the characteristic impedance-source function for the active nerve membrane during the passage of a normal impulse without superposition of any testing current. This total function can be separated into two parts, a passive component which represents the quiescent physical-chemical properties of the membrane, and an active or 'live' component which includes the energy-yielding mechanism of the impulse. Using experimental results quoted in the literature supplemented by data from new experiments, it has been possible to evaluate, with relatively low accuracy, the passive part of the function, and from this to work back to an approximate numerical evaluation of the active part of the function. By measuring all of the critical quantities involved in the analysis for a single type of nerve, or preferably for an individual specimen, it should be possible to improve greatly the quantitative accuracy of the results. Accurate values for the impedance-source function should prove useful in testing thermodynamically adequate theories for the conversion of biochemical energy to bioelectrical energy.

Action potentials of the cerebellar cortex

elicited by stimulation of olivo-cerebellar fibers GORDON M. SCHOEFFLE *Dept of Physiology, School of Medicine, Washington Univ, St Louis, Mo* Cerebellar action potentials are recorded by means of a unipolar lead (microelectrode) at various levels within the cortex of the dog in response to single shock stimulation of olivo-cerebellar fibers. The stimulating needle electrodes are thrust into the brain stem from above in the region of the inferior olivary nucleus. Voltage changes associated with post synaptic responses when recorded between folia or in the molecular layer of each folium tend to be manifest as several successive positive deflections. At regions containing the Purkinje cell layer, granular layer, or central white lamina the successive post synaptic responses exhibit pronounced negative components. In fact the first post synaptic action potential may show no initial positivity. Such a series of results is reproducible from folium to folium as the recording needle electrode is progressively thrust deeper into the cortex at an acute angle with the plane of the brain surface. Measurements of electrode position taken in connection with histological examination of the cortex appear to be precise to within approximately three tenths of a millimeter. The phase reversals observed are consistent with considerations of volume conductor theory which include the concept of neurones as polarized cylindrical structures which, however, do not undergo depolarization in terminal regions at any time during activity. No phase of any particular response persists for more than a few milliseconds and no underlying slow potential waves are apparent.

Rapid spontaneous variations in blood pressure HENRY A. SCHROEDER *Dept of Internal Medicine, Washington Univ School of Medicine and Barnes Hospital, St Louis, Mo* When blood pressure in the brachial artery of man is measured by Hamilton's optical manometer, spontaneous variations occur from beat to beat which may be of relatively considerable magnitude. Fifty records of blood pressure of normotensive and hypertensive subjects and those with coarctation of the aorta were examined for these variations. In half the difference in systolic pressure from one beat to an adjacent one was 10 mm Hg or more. The average systolic difference was 10.3 mm Hg, the average diastolic 7.0. Various patterns were seen, in some cases respiratory variations were marked, in others two or three beats with high pressure were followed by two or three with lower. In several cases similar variations were found in records made of pressure in the femoral artery. Hypertensive patients on the whole showed greater variations in beat to beat pressure than did normotensive ones, and there was usually little respiratory variation. These changes could also be detected by

the auscultatory method when the pressure cuff was inflated exactly to systolic pressure

Absence of antifibrillatory effect in quaternary nitrogen compounds JOHN E. SCHULTS (by invitation) and JOSEPH R. DiPALMA *Depts of Physiology and Medicine, Long Island College of Medicine, Brooklyn, N. Y.* The activity of a compound as an antifibrillatory drug was determined by means of a thyatron stimulator set at 600 impulses/min and connected through a rheostat to the right auricle of an anesthetized open chest cat. The minimal amount of current, in milliamperes, necessary to induce fibrillation was determined before and after the administration of a drug. The degree of difference was the index to the activity of the compound. The drug to be tested was administered in a dose of 5 mg/kg i.v. and the fibrillation threshold determined immediately and at 10- and 20-minute intervals. Dawes (*British J. Pharm. & Chemotherapy* 1:90, 1948) noted in testing various quinoline derivatives for antifibrillatory activity that, when their tertiary nitrogen was changed to a quaternary one, these compounds lost their potency. A recently synthesized compound, N-methyl-N-(3,4-dimethoxybenzyl)-(4-methoxyphenyl)-ethylamine hydrochloride, is a potent antifibrillatory agent. When the tertiary nitrogen of this compound is converted to a quaternary one by the addition of a methyl and halogen groups the activity is lost and in some respects the compound now resembles muscarinic drugs. Other quaternary nitrogen compounds such as tetraethyl ammonium chloride, dibenamine and mecholyl, some of which are related to antifibrillatory drugs, were tested by this method and found to have no antifibrillatory activity and some even lowered the fibrillation threshold.

A method for determination of the volume of distribution of metabolized substances IRVING L. SCHWARTZ, MURRAY RABINOWITZ and DAVID SCHACHTER (introduced by HOMER W. SMITH) *Dept. of Physiology, New York Univ. College of Medicine, New York City.* Following an intravenous injection of mannitol, Newman, Bordley and Winternitz (*Bull. Johns Hopkins Hosp.* 75:253, 1944) utilized the relationship between 1) renal clearance, 2) volume of distribution, and 3) decrement in plasma concentration with time to determine 1) and 2). It is now known (*J. Lab. & Clin. Med.* 32:192, 1947; *Proc. Soc. Exptl. Biol. & Med.* 66:62, 1947) that mannitol is metabolized. In order to measure the total clearance (renal and metabolic), the rate of infusion (IV) required to maintain a constant plasma level was determined, thereafter the infusion was discontinued and the decrement in plasma concentration with time was observed. Under conditions of constant total clearance, O , the volume of dis-

tribution, V_m , was calculated as
$$V_m = \frac{O(t' - t)}{\log \frac{P}{P'}}$$

where P and P' are the plasma concentrations at times t and t' respectively. It is assumed that P and P' represent the concentration throughout the entire volume of distribution. In 3 experiments on 2 dogs, the volume of distribution of mannitol determined simultaneously with that of inulin (*Proc. Soc. Exptl. Biol. & Med.* 68:507, 1948) was as follows:

Mannitol Space		Inulin Space	
cc	cc/kg	cc	cc/kg
4,750	206	4,850	210
4,775	201	4,900	208
3,230	199	3,310	203

Transcapillary exchange of inulin in man IRVING L. SCHWARTZ, DAVID SCHACHTER and NORBERT FREINKEL (introduced by HOMER W. SMITH) *Dept. of Physiology, New York Univ. College of Medicine, New York City.* The movement of inulin between plasma and interstitial fluid was studied in each of 3 normal men utilizing T_{1824} space as a measure of plasma volume, and inulin space (*Proc. Soc. Exptl. Biol. & Med.* 68:507, 1948) as a measure of extracellular fluid. Following a single intravenous injection of inulin serial samples of venous blood and urine were collected for 24 hours. The amount of inulin (Z) in the interstitial space at any time (t) following administration may be calculated from the injection dose (D), total cumulative urinary excretion at t , (UV), plasma water inulin concentration (P_{wIn}) and plasma water volume (P_{wv}) by the expression $Z = D - UV - P_{wIn}P_{wv}$. The volume of interstitial fluid (I_v) is $ECF - P_{wv}$, hence Z/I_v represents the virtual concentration of inulin in interstitial fluid if it were mixed evenly throughout that compartment. The simultaneous plasma and interstitial fluid concentrations plotted against time demonstrate: a) early rapid movement of inulin from plasma to interstitial fluid, b) maximal concentration of inulin in interstitial fluid in 15 to 20 minutes at a value below the plasma concentration, c) identity of plasma water concentration (P_{wIn}) and mean interstitial fluid concentration (Z/I_v) 40 to 50 minutes after injection, d) Z/I_v remains higher than P_{wIn} thereafter because of the gradient between interstitial fluid and plasma. Two important implications of these studies are: 1) a single injection of inulin should not be used to determine the volume of distribution since true equilibrium never occurs and mean virtual equilibration of interstitial fluid with plasma water occurs at only one instant in time, 2) reversal of flow of inulin between plasma and the most avail-

able phases of the interstitial fluid occurs before the point of mean equilibration

Potential of the prolactin effect ERWIN SCHWENK (by invitation), SIBYLLE TOLKSDORF (by invitation), ROY McCULLAGH (by invitation) and RICHARD TISLOW *Biological Research Lab and the Chemical Research Div of Schering Corporation, Bloomfield, N J* An increase in the effect of anterior pituitary lactogenic hormone preparations (Prolactin) has been observed when Sørensen's phosphate buffer (pH 7.4) was added to the aqueous solution of the hormone. The assay used was the crop sac weight response in white Carneau pigeons according to the method of Riddle and Bates. The effect was observed both by subcutaneous and intramuscular routes of administration. When averaging repeated assays of the International Standard and Schering Substandard of the lactogenic hormone, the increase in response to the two standards in the presence of buffer was approximately 2-fold. The effect was noted with Prolactin fractions of various purity and potency ranging from starting material of crude pituitary extracts with a potency of 0.4 IU/mg to highly purified fractions containing 35 IU/mg. It was observed with phosphate buffer of 0.1, 0.2, 0.4 and 0.6 molarity. The effect was only noticed when the hormone was injected in the buffered solution, and not upon separate injection of buffer and hormone solutions. The effect was not observed when phosphate-buffered Prolactin was dialysed free of buffer, precipitated and redissolved in water. The increased response appeared again upon addition of buffer to the solution. Other buffers, such as acetate and arginine, produced a similar effect.

Response of individual pacinian corpuscles to external stimulation DONALD SCOTT, JR (introduced by FRANK BRINK, JR) *Johnson Foundation, Univ of Pennsylvania, Philadelphia, Penna* Single Pacinian corpuscles can be dissected from the mesentery of the cat with the single sensory nerve fibre and circulation uninterrupted. The electrical activity can then be studied by lifting the corpuscle on to a fine cotton wick electrode connected to recording equipment. The corpuscle will respond to steady pressure by a glass rod with a series of impulses, the average frequency of which can be altered by increasing or decreasing the pressure. The threshold value for this form of stimulation lies below 5 mg. The corpuscle is much more sensitive to vibratory stimulation as applied by a fine vibrating glass rod or a pure tone. Treatment of the corpuscle with citrate will increase the excitability to the point of spontaneous activity. Analysis of the length of interval between adjacent impulses after the scheme of Brink, Bronk and Larrabee (*Ann New York Acad Sci* 47: 457, 1946) shows that the corpuscle responds in the

manner found by these authors where a fundamental unit interval was shown to separate many impulses while others were separated by simple multiples thereof. The length of the fundamental interval of the corpuscle is 4-5 msec. Careful examination of photographic records where two or more fundamental intervals separate adjacent impulses shows small oscillations of the base line between impulses which have the same period as the fundamental interval of the conducted impulses. This suggests the existence of a continuous oscillation of the excitability of the corpuscle.

Anaphylactic release of histamine and heparin from the isolated dog liver A. E. SCROGGIE (by invitation) and L. B. JAKES *Dept of Physiology, Univ of Saskatchewan, Saskatoon, Sask, Canada* The anaphylactic reaction of the livers of dogs sensitized to horse serum was studied by perfusing the organ with the antigen both *in situ* and isolated. The assay of perfusates for histamine and heparin, before and after perfusion with antigen, demonstrated: 1) When the liver was perfused *in situ* the release of large amounts of these substances occurred in 2 of 6 animals. 2) When the livers were isolated, perfusion with antigen in 'silicone' blood caused a smaller but significant release of histamine and heparin in 6 of 9 animals. 3) When isolated livers were perfused with antigen in Tyrode's solution no release of histamine or heparin occurred. Subsequent perfusion with blood and the addition of antigen to this blood also caused no release of the anaphylotoxins. 4) When antigen was perfused in Tyrode's solution through the isolated livers of 2 dogs which had received two sensitizing doses of antigen, as compared with the single sensitizing dose given to the dogs of 1), 2) and 3), a release of histamine and heparin was obtained, of the order of that in 2). From these results, it is concluded: 1) it is possible to demonstrate the Schultz-Dale phenomenon with canine tissue, by using the isolated liver and measuring the release of histamine and heparin, 2) this reaction is assisted by using 'silicone' blood in place of Tyrode's in the perfusion. This is probably due to blood maintaining normal function of liver cells, rather than entering into the anaphylactic mechanism resulting in the liberation of the anaphylotoxins.

Metabolism in *Colpidium campylum* GERALD R. SEAMAN (introduced by CHARLES G. WILBER) *Biological Laboratory, Fordham Univ, New York City* *Colpidium campylum* rapidly utilizes acids of the tricarboxylic acid cycle. The addition of pyruvate results in an increased oxygen consumption of 120%, α -ketoglutarate of 102%, fumarate of 90%, malate of 97%, oxaloacetate an increase of 85%. Added citrate causes no increase in oxygen consumption. Malonate inhibits the oxidation of pyruvate in *Colpidium*. Fumarate, succinate, and

α -ketoglutarate release the inhibition Citrate, however, does not release the malonate inhibition Malonate inhibition in the presence of citrate is released by fumarate to approximately the same extent as when citrate is absent Fumarate and α -ketoglutarate are recovered when colpidia are incubated with pyruvate The addition of fumarate to pyruvate increases the recovery of α ketoglutarate by 140% Pyruvate, fumarate, and lactate are recovered when oxaloacetate is the sole substrate As a result of fumarate release of malonate inhibition, there is an added utilization of pyruvate and an added recovery of succinate The amounts of cytochrome C, DPN, and glutathione in *Colpidium* are (in γ /mg dry weight of cells) respectively 0.17, 0.82, 1.08 The ATPase activity is 4.7 γ inorganic P liberated/15 min/mg dry weight of cells Transamination reactions in *Colpidium* will be reported

Effect of 933F on the action of dibenamine

JOHN C SEED AND ELIZABETH A MCKAY (introduced by J H WILLS) *Pharmacology Section, Medical Division, Army Chemical Center, Md* Inasmuch as 933F (piperidinomethyl-3-benzodioxane) and dibenamine (dibenzyl- β -chlorethylamine) both block the pressor action of epinephrine, it was felt that the two drugs might act by way of the same mechanism If this were true, one should be able to prevent the action of dibenamine with 933F Five hours after the administration of 5 mg/kg of 933F to the nembutalized dog, 5 μ gm/kg of epinephrine causes a marked pressor response Five hours after the administration of 10 mg/kg of dibenamine, 5 μ gm/kg of epinephrine causes a marked depressor response Five hours after the administration of 5 mg/kg of 933F followed in 3 min by 10 mg/kg of dibenamine, 5 gm/kg of epinephrine causes a marked pressor response which is of the same magnitude as if dibenamine had not been given at all

Electrolyte metabolism following massive glucose, mannitol, urea infusions in normal subjects during hydration and dehydration DONALD W SELDIN AND ROBERT TARAIL (introduced by DONALD H BARRON) *Dept of Internal Medicine, Yale Univ School of Medicine, New Haven, Conn* Following glucose or mannitol infusion, serum sodium concentration fell sharply, indicating movement of water out of cells and perhaps transfer of sodium into cells Increased Na excretion could not account for the fall, since the concentration of Na in urine was well below that in serum The fall in serum Na concentration was not sufficient to prevent some rise in osmotic pressure of serum When these changes occurred, the excretion rate of Na increased 2- to 6-fold In contrast to glucose and mannitol, urea, although excreted in comparable amounts, neither increased Na excretion nor significantly altered serum Na concen-

tration Increased Na excretion following glucose and mannitol infusions may be due to expansion of extracellular volume rather than to an osmotic effect in the renal tubules alone, since comparable urea infusions neither expand the extracellular volume nor augment Na excretion The metabolism of K, though closely linked to cellular metabolism, is also affected by osmotic distortions of internal environment Infusions of mannitol, glucose or urea had some effect on K excretion, producing slight initial increases during dehydration and definite decreases during water diuresis Serum -K concentration was not significantly affected by expansion or contraction of extracellular volume The single striking change in serum K occurred following glucose infusion during water ingestion when serum concentration fell by 25%, associated with transfer of 15 meq of K into cells This occurred when extracellular volume was contracting and glucose utilization was accelerated, and was probably related to glucose metabolism

Graded arterial pressure decrement and renal clearance of PAH, creatinine, and sodium EWALD E SELKURT, PHILIP W HALL (by invitation), and MERRILL P SPENCER (by invitation) *Dept of Physiology, Western Reserve Univ Medical School, Cleveland, Ohio* When arterial pressure is gradually decreased by tourniquet action on the dorsal aorta just above the left renal artery in the dog, the clearance of creatinine decreases at first gradually from about 150 to 90 mm Hg, then more rapidly to cease entirely at about 50 mm Hg The relationship of clearance to pressure is thus curvilinear, concave to the pressure axis The clearance of PAH declines more slowly than that of creatinine, remaining near the control value until about 80 mm Hg, then decreasing abruptly to extinction as glomerular filtration ceases and anuria ensues When clearance of PAH is related to pressure it shows curvilinearity with even greater concavity than that of creatinine The more rapid decline of creatinine clearance signifies a decrease in filtration fraction as pressure is decreased Renal tubular reabsorption of sodium was found to remain essentially complete throughout the range of glomerular filtration rates studied Nevertheless, even though urinary excretion of sodium was small, there was a definite tendency for it to decrease further as glomerular filtration was reduced, and at approximately 50% of the control filtration rates urinary excretion of sodium ceased almost entirely

Histo-physiology of the adrenal cortex HANS SELKE and HELEN STONE (by invitation) *Inst de Médecine et de Chirurgie expérimentales, Univ de Montréal, Montréal, Canada* Experiments on the rat reveal that—in addition to mere stimulation or inhibition of secretion—the adrenal cortex can respond in a highly specific manner to certain

agents Chronic treatment with lyophilized beef-anterior-pituitary tissue (LAP), and to a lesser extent with extracts of various necrotic tissues (e g , Walker rat tumor, rat kidney), cause myeloid metaplasia of adrenal cortical cells, with the formation of both leucocyte and erythrocyte forming elements Testoid compounds (e g , methyl-testosterone) cause metaplasia of adreno-cortical into ordinary fat cells, exhibiting the typical 'signet ring' appearance and containing a single, large fat vacuole Simultaneous treatment with LAP and methyl-testosterone cause hemopoiesis in a fat cell-containing stroma This may result in the complete transformation of fasciculata and reticularis into typical bone-marrow tissue, while the glomerulosa remains intact Even acute and intense overdosage with purified corticotrophin fails to cause such severe loss of adrenal cortical lipid granules as is produced by systemic stress during the alarm reaction Indeed, pretreatment with corticotrophin inhibits the loss of cortical lipid granules which is normally produced by alarming stimuli or folliculoid hormones Hence, in addition to increased corticotrophin secretion other factors must prevail during the alarm reaction to effect the usual intense discharge of cortical lipids Experimental procedures will be discussed which permit the production in the adrenal cortex of specific structural changes having hitherto received little attention The most important among these are the formation of intracellular colloid bodies, cytoplasmic 'chromatin-like' basophilic granules, fibrinoid degeneration of adreno-cortical cells, megakaryocyte-like giant cells and of "pseudolumina" with holocrine secretion of adreno-cortical cells The functional significance of these lesions will be discussed

The pattern of localization in the motor cortex of the rat P H SETTLAGE (by invitation), W G BINGHAM (by invitation), H M SUCKLE (by invitation), A F BORGE (by invitation) and C N WOOLSEY *Depts of Anatomy, Surgery and Physiology, Univ of Wis, Medical School, Madison, Wis* The findings of Woolsey and LeMessurier (*Federation Proc*, 1948), that the pattern of cutaneous representation in somatic area I (post-central homologue) of the rat's cerebral cortex consists of "a somewhat distorted picture of a rat with its various parts related to one another in much the same manner as in the actual animal", have led us to make a detailed study of the pattern of localization in the motor cortex of this rodent The motor area lies medial and rostral to the tactile cortex and corresponds approximately to Krieg's areas 4, 6, 10 and 8 The axial musculature from tail to neck is represented along the medial edge of the motor area in a caudo-rostral sequence The limbs are represented more laterally, with their apices meeting the apices of the limbs of the

tactile pattern The motor area for the head fills the rostral part of the field and extends laterally to the rhinal sulcus The whole motor pattern is essentially a mirror image of the 'postcentral' tactile pattern Together the tactile and motor systems of this animal show a clear and simple plan of organization which may prove fundamental to an understanding of less diagrammatic arrangements in other forms

Polyphenoloxidase activity of blood serum BERNARD SHACTER (introduced by MICHAEL B SHIMKIN) *Lab of Experimental Oncology, Univ of Calif Medical School, San Francisco, Calif and the National Cancer Inst, National Institutes of Health, U S P H S, Bethesda, Md* The phenoloxidase activity of human blood serum was investigated in the Warburg manometer In the presence of serum the oxidation of catechol is initially retarded and then accelerated beyond the rate of auto-oxidation of the substrate Adrenaline is acted upon in a similar fashion The activity is apparently enzymatic since it is completely abolished by cyanide and by heating the serum to 80° for one hour The rate of catechol oxidation increases as the temperature is raised from 25° to 43° and as the pH is increased from 6.6 to 7.8 Under fixed conditions of pH and temperature the enzymatic activity is proportional to the amount of serum used Tyrosine, p-cresol, and resorcinol remain unoxidized when added to serum, while the auto-oxidation of hydroquinone is retarded p-Aminobenzoic acid and sulfanilamide in 0.1 M concentration inhibit the oxidase activity The data indicate the presence in blood serum of a polyphenoloxidase, specific for ortho diphenols

Electrical phenomena in the squid giant axon ABRAHAM M SHANES *Dept of Physiology and Biophysics, Georgetown Univ School of Medicine, Washington, D C and Marine Biological Lab, Woods Hole, Mass* The effects of calcium, potassium, veratrine, yohimbine, procaine, cocaine and DDT, on 3 components of the action potential following single spikes, have been studied oscillographically after localized application to axons from *Loligo pealii* One component, a damped high frequency oscillation present in all fibers and dying away usually in less than 10 milliseconds, is closely related to the very similar subthreshold response The negative after-potential (NAP), present in 50% of the untreated axons, has a maximum amplitude of 100-200 microvolts and disappears exponentially within 200 milliseconds, with veratrinization all fibers exhibit NAP, but this declines in two exponential stages, viz, an initial rapid one terminating in about 100 milliseconds and a slower phase lasting about one second A positive after-potential, evident only after yohimbine, reaches a maximum of less than 50 microvolts within 75-100 milliseconds and lasts about one second Cocaine and

procaine (01–02%) reversibly depress the oscillations and NAP whereas veratrine and lowered potassium enhance them. Calcium acts on the oscillations as described by Arvanitaki, it depresses the NAP when veratrine is absent, but increases it in the latter's presence. Only veratrine altered the time constant of NAP decline. DDT was completely inert. The oscillations grow in veratrine but decline in yohimbine during repetitive stimulation. These observations, and others to be described later for crab and frog nerve, appear explainable largely in terms of potassium transport near the fiber surface as governed by electrochemical factors and a labile permeability and metabolism.

Production of adeno-carcinoma of breast in Wistar rats by the gastric instillation of methylcholanthrene HARRY SHAY, ERNEST A. AEGERTER (by invitation), MARGOT GRUENSTEIN (by invitation) and S. A. KOMAROV *Samuel S. Fels Research Inst. and the Dept. of Pathology, Temple Univ. School of Medicine, Philadelphia, Pa.* Wistar strain rats placed on Zucker's calcium-free diet are known to readily develop ulcerations of the antrum of the stomach (*J. Nutrition* 30: 301, 1945). By instilling methylcholanthrene (melting point 180° corrected) in 0.5 cc olive oil by stomach catheter (Shay and Gruenstein, *J. Lab. and Clin. Med.* 31: 1384, 1946), we hoped to create suitable conditions for induction of carcinoma in the ulcerated stomach. Such experiments were performed on 5–7 weeks' old rats weighing 60–70 gm and methylcholanthrene administered in 2 mg doses (6 days a week) for 6–14 months. No gastro-intestinal tumors resulted but breast adeno-carcinoma developed in 15 out of 28 females. Calcium deficiency was apparently not essential for development of these tumors since they occurred in 4 out of 10 methylcholanthrene treated females on colony diet. The shortest period for development of tumors was 143 days and the longest 418 days. No tumors were observed in 12 similarly treated castrated females and 43 males, 24 of which were castrated. The high incidence of tumors induced distally by methylcholanthrene is significant, since in 15 years with an annual turnover of 2500 animals no breast adeno-carcinoma occurred spontaneously in our colony of Wistar strain rats. Keston (Conference on Ageing, Wistar Institute—June 1946) found no breast adeno-carcinoma in 630 autopsies on Wistar rats (mean age 810 days, S. D. 210 days), 164 of which had other tumors.

Isotopic studies of potassium exchange rates between cellular elements and plasma of human and canine blood *in vitro* C. W. SHEPPARD and W. R. MARTIN (introduced by ALEXANDER HOLLANDER) *Biology Division, Oak Ridge National Lab., Oak Ridge, Tenn.* Fresh heparinized blood is maintained in an apparently viable state for 8

to 10 hr *in vitro*. Hemolysis is generally at or below the lower limit of visual detection. Hematocrits are routinely determined and lie within 2½% of the mean. There is some evidence of occasional systematic increases of potassium concentration in the plasma late in the experiments, the total change being about 15%. In human blood the concentration of isotope (K^{42}) in the plasma decreases fairly rapidly. Equal specific activities of cells and plasma are reached at about 18 hr. The curve is a smooth exponential with a single half value time corresponding to an exchange rate of about 10^{-12} millimol of potassium/hr/cell. In the dog the curve shows an initial rapid exponential decline to an elevated base line which slowly declines at about 1%/hr. Removal of a fraction of the cells containing leukocytes, platelets and probably young erythrocytes eliminates the rapid exponential phase. The slow decline is evidently characteristic of the exchange of potassium in mature canine erythrocytes, the rate being about 4×10^{-16} millimol/hr/cell.

A fluorometric method of determination of adrenalin in blood WM. W. SHINGLETON and H. M. BAKER (introduced by K. S. GRIMSON) *Dept. of Surgery, Duke Univ., Durham, N. C.* Numerous chemical and biological methods planned for determination of adrenalin in blood have yielded variable results and failed to consistently determine small amounts of adrenalin which might be present in the circulating blood normally or during abnormal circumstances. Three reported chemical methods have been tested. The colorimetric method of Shaw, its modification by Raab, and the fluorescent method of Lehman and Michealis yielded results which were not consistent or capable of repetition. A new method has been developed employing the selective adsorption of adrenalin by $Al(OH)_3$ at pH 8.3 and a fluorescent determination of this adsorbed adrenalin. Fluorescence of the material oxidized by 25% NaOH was measured using a Coleman Electronic Photofluorometer equipped with special excitation and transmission filters. This method was tested many times using freshly drawn heparinized human venous blood. Plasma obtained by centrifuging was divided into three equal samples. Known equal amounts of adrenalin chloride were added to two of the samples. One cc of formaldehyde was then added to one of the two adrenalin treated samples. Twenty-four hrs later fluorescence of each sample was determined. The fluorescence of the sample without adrenalin and that with adrenalin plus formaldehyde was approximately equal and low. Fluorescence of the third sample containing adrenalin alone showed a high end point approaching 90% of the fluorescence of a sample of water with the same quantity of adrenalin and similarly treated. Using this method, preliminary experi-

ments have been performed which indicate that relatively small amounts of adrenalin injected into dogs or rabbits are detectable

Hepato-renal factors XXVII Biological fractionation of humoral VEM and VDM in renal hypertension (dogs) EPHRAIM SHORR and BENJAMIN W ZWEIFACH *Dept of Medicine, Cornell Univ Medical College and The New York Hospital, New York City* The initial acute stage of experimental renal hypertension in dogs is associated with the appearance in blood of the renal vaso-excitor, VEM. During the subsequent chronic hypertensive stage, the blood progressively reverts to a neutral reaction, as judged by the rat meso-appendix test, presumably due to the presence of both VEM and the oppositely acting hepatic vaso-depressor, VDM, in physiologically equivalent amounts. More detailed analyses have since been made of the sequence in which these vasotropic principles appear in the development of the hypertensive syndrome, utilizing procedures which permit the separate quantitation of each factor when both are present. Development of antisera to VDM (ferritin) provided a tool for selectively inactivating the VDM components of hypertensive blood, and unmasking VEM. Conversely, the ability of normal kidney slices to inactivate VEM aerobically, without affecting VDM, permitted quantitation of the VDM titer. Untreated blood samples, from dogs with renal hypertension (Goldblatt clamp) gave vasoexcitor (VEM) rat tests in the first few weeks after clamping, during the period of rising blood pressure, and thereafter were neutral. Utilizing these fractionation procedures, VDM was found to appear as early as 7-14 days after clamping, during the period of VEM predominance. VDM titers then rose progressively until they masked humoral VEM in the rat meso-appendix test. Thereafter, there was a shifting balance between VEM and VDM, with transitory predominance of each. In animals with fatal malignant hypertension, the terminal stage generally was associated with a shift in equilibrium, with progressive predominance of VEM.

Effect of hypothermia on cardiodynamics WILLIAM J SHRIBER (introduced by A H HEGNAUER) *Dept of Physiology, Boston Univ School of Medicine, Boston, Mass* Dogs weighing 9-15 kg were anesthetized by intravenous pentothal. The right auricle was catheterized through the right external jugular vein, and the left ventricle was catheterized via the left carotid artery. Intracardiac pressures were recorded with critically damped electrical strain gauge manometers together with simultaneous electrocardiograms. The animals were then cooled in 2-4°C water baths. Serial photographic records were taken until death. Left ventricular systolic pressure remained fairly constant until rectal temperatures of 25-23°C and

then fell rapidly. Right auricular systolic pressure remained relatively constant to similar thermal levels and then rose rapidly. These sudden changes in pressure appeared to be correlated with the cessation of respiration. The fall in the left ventricular pressure probably occurred as a result of an inadequate pulmonary circulation and this in turn resulted in an inability to maintain arterial blood pressure. The sudden increase in right sided pressure was again probably attributable to pulmonary circulatory resistance which led to right heart failure. Conceivably, hypoxia of the cardiac muscle might be a factor in the failure of the heart.

Diet and the activity of the insulin-inactivating system of rat liver BENJAMIN SIMKIN (by invitation), ROBERT H BROH-KAHN and I ARTHUR MIRSKY *The May Institute for Medical Research of the Jewish Hospital, Cincinnati, Ohio* Our previous investigations revealed a marked diminution of the content of the insulin-inactivating system (insulinase) per gram of rat liver during a 72-hr fast and a restoration of the content of this system to normal values following a 48-hr period of re-feeding a balanced diet. The present investigation is concerned with the influence of various types of food-stuffs on the restoration of insulinase activity during such re-feeding after a 3-day fast. Re-feeding a high (85%) carbohydrate diet restored the insulinase content to values above those obtained by re-feeding a balanced diet containing 50% carbohydrate. Re-feeding a high (85%) fat diet, on the other hand, restored the insulinase content to values significantly below those obtained by refeeding with the balanced or the high carbohydrate diet. Inasmuch as the diets were iso-caloric and the rats gained approximately equal weights during the period of their re-feeding, it seems probable that the administration of a high fat diet definitely diminishes the content of the insulin-inactivating system in the liver. In other experiments, rats were force-fed by tube with increasing amounts of high carbohydrate and high fat diets. The various results will be presented and their significance briefly discussed.

A quantitative comparison of Goldberger's augmented unipolar limb leads (aV) with Wilson's original V-leads ERNST SIMONSON and ANCEL KEIS *Laby of Physiological Hygiene, Univ of Minnesota, Minneapolis, Minn* Goldberger (Unipolar Lead Electrocardiography, Philadelphia, 1947) considers his two-terminal (aV) electrode to be identical with Wilson's three-terminal (V) 'unipolar' electrode except for a 50% larger amplitude, so that both electrodes may be used interchangeably. Among electrocardiographers preferences for the aV or the V-electrode vary but no quantitative comparison has been made. In 20 normal men and in 6 patients with abnormal axis deviation, the amplitudes of the QRS-complex and

the T-wave in the three limb leads were taken with Goldberger's two lead and Wilson's three lead terminal. In the arms leads the mean augmentation obtained with Goldberger's method agrees fairly well with the predicted 150% of the Wilson leads, but in lead aV_F the mean is 184 (QRS-complex) or 187% (T-wave). The finding in aV_F was confirmed in 22 other subjects. Moreover, in all leads the variability of augmentation between individuals is so great that prediction of the ratio aV/V for the individual is impossible. The results show that Wilson's three lead terminal and Goldberger's two lead terminal are not interchangeable, and that standards for one method are not applicable to the other method. The results have some bearing on the degree of validity of Einthoven's triangle hypothesis.

Diurnal variations in glomerular activity in normal man and in patients with congestive heart failure. JONAS H SIROTA, DAVID S BALDWIN and HERMAN VILLARREAL (introduced by HOMER W SMITH) *Dept of Physiology and Medicine, New York Univ College of Medicine, New York City*. Renal clearances (4- to 6 hr periods) of insulin, p-aminohippurate and endogenous creatinine were determined throughout 24 hr in 13 normal males and in 5 patients with congestive heart failure with persistent edema. Test substances were administered by a constant delivery pump through a plastic intravenous catheter. Urine was collected by spontaneous voiding in normals and by catheterization in heart failure patients. Blood was drawn at the midpoint of each period. With few exceptions the subjects were at bed rest for at least 24 hr prior to as well as during the period of observation and slept approximately from 8 P.M. to 6 A.M. No change in the dietary regimen was made during the test day. Waking clearances were compared with those during sleep and expressed as night to day ratios (N/D). In the normals the average N/D ratio for C_{IN} was 0.94, for C_{TAH}, 0.97, and for endogenous creatinine clearances, 0.97. In patients with heart failure the average N/D ratio for C_{IN} was 1.18, for C_{TAH}, 1.14, and for endogenous creatinine clearances, 1.16. The endogenous creatinine/insulin clearance ratio averaged 0.92 in the normals, and 0.75 in patients with heart failure. It is concluded that glomerular activity is typically unchanged or decreased during sleep in normal subjects, whereas it typically increases during sleep by a significant amount in heart failure. The endogenous creatinine clearance is not a reliable index of filtration rate in subjects with heart failure.

Augmentation by catechol and p-cresol of the oxidation of proteins by mushroom tyrosinase. IRWIN W SIZER and CLYDE O BRINDLEY (by invitation) *Dept of Biology, Massachusetts Institute of Technology, Cambridge, Mass.* In previous

experiments we have shown that certain proteins can be oxidized by tyrosinase and, in the case of invertase, this oxidation is accompanied by a decrease in invertase activity. Since the oxidation of certain substrates by tyrosinase is accelerated by the addition of an activator (See Nelson, J. M. and Dawson, C. R., *Adv. in Enzymol.* 4: 99, 1944) we have tested such activators on the tyrosinase protein systems. As little as 1×10^{-4} M catechol or p-cresol greatly accelerates and renders more extensive the action of tyrosinase on certain proteins. In the action of tyrosinase on invertase the phenolic activator seems to be coupled to the system like a co-enzyme. The reduced and oxidized form of the phenolic activator constitute a reversible oxidation-reduction system, i.e., catechol \rightleftharpoons o-benzo-quinone (see Nelson and Dawson). A side reaction is the slow formation of quinone polymers from the oxidized forms of the phenolic activators. These intermediary and final oxidation products of catechol had no effect on invertase activity in the absence of tyrosinase. Insulin oxidation by tyrosinase is greatly accelerated by the presence of traces of catechol, as indicated by a decrease in the ultraviolet absorption spectrum and a decrease in biological activity. Similar results are obtained with crystalline pepsin where tyrosinase in the presence of catechol produced a marked change in the ultraviolet absorption spectrum of pepsin and a decrease in peptic activity. Indications have been obtained that tyrosinase in the presence of certain phenolic compounds will oxidize many other proteins containing a high percentage of tyrosyl groups.

Comparison of transmission spectra of blood in the human ear flushed by histamine with those obtained after heat flushing. WILLIAM SLEATOR, JR., JAMES O. ELAM, D. J. KILIAN, W. N. ELAM, JR. (introduced by H. L. WHITE) *Dept of Physiology and Dept of Surgery, Washington Univ School of Medicine, St. Louis, Mo.* Using the monochromator and amplifier arrangement already described (Neville *et al.*, *Federation Proc.* 1949), the percentage transmission of the ear lobe or pinna of a number of normal subjects was measured as a function of wave length from 5000 Å to 11,000 Å. Curves were taken with the subjects breathing air, 100% O₂, and 12% O₂, and with the ears flushed by means of histamine administered electrophoretically, or by means of heat (which has been the principal arterializing agent used in oximetry). For both heat and histamine the percentage transmission when the subject breathed pure oxygen was, on the average for λ less than 7800 Å, about 15 to 20% higher than when the subject breathed 12% O₂, for λ greater than 7800 Å the 100% O₂ curve was 3 to 10% lower than the 12% O₂ curve. With histamine the spectrum when the subject breathed room air followed the 100% O₂ spectrum.

closely through the whole wave length range, rarely differing by as much as 4%. This would be expected if the ear were really arterialized since normal arterial O_2 saturation is known to be above 95% on air and 99–100% on pure O_2 . With heat, however, the room air curves were markedly (10–20%) below the 100% O_2 curves, but followed the 12% O_2 curves very closely (3–6%). The presence of a significant fraction of venous blood (O_2 saturation 75–80%) in the heated ear would account both for the large difference between 100% O_2 and air, and the small difference between air and 12% O_2 .

Peripheral vascular reactions in the wing of the bat after total-body X irradiation DOUGLAS E SMITH, GEORGE SVIHLA (by invitation) and HARVEY M PATT *Biology Division, Argonne National Lab, Chicago, Ill*. A number of peripheral vascular reactions (erythema, hyperemia, increased capillary fragility, hemorrhage) have been described in man and laboratory animals following exposure to X radiation. In the hope of obtaining a definitive picture of the development of these phenomena microscopic observations and cinema microphotographs were made of vascular beds in the wing of the living, intact bat (*Myotis lucifugus*) before and at various intervals after total-body X irradiation. Studies were made on several hundred animals during the late autumn and winter. Until high dosages (10,000–60,000 r) were reached no peripheral vascular changes were observed. Within an hr after such dosages large numbers of leucocytes, many of which stuck to the vessel walls, were apparent. This phenomenon which was most marked during the first 24 hr after irradiation persisted for several days. Early after irradiation the blood seemed to be less viscous than normal only to become more viscous at the end of 24 to 36 hr and remain so until death. Consistent changes in vessel diameter, blood flow and venomotion were not observed, nor were any indications of hemorrhage. Toxicity experiments suggested that the bat might be highly resistant to X irradiation, for in these experiments life span was shortened only after dosages of 15,000–60,000 r. Significantly, only such high dosages produced the peripheral vascular changes noted above.

Observations of the action of the cardiac, pulmonic and aortic valves of the beating heart (motion picture) H L SMITH (by invitation), HIRAM E ESSEX, and E J BALDES *The Mayo Clinic and Mayo Foundation, Rochester, Minn*. Perfusion of the isolated heart of the rabbit or dog makes possible direct observation of the action of the cardiac, aortic and pulmonic valves. Observation of the mitral and tricuspid valves is facilitated by incising and retracting the atrial walls. With proper illumination, the pulmonic valves can be observed by cutting and retracting the walls of

the common pulmonary artery. The observation of the aortic valves requires a special cannula and an apparatus for providing peripheral resistance to the flow from the left ventricle. Certain observations are discussed.

Effect of salt-sugar solution and DCA on lactation THOMAS C SMITH (introduced by F L HISAW) *The Biological Labys, Harvard Univ, Cambridge, Mass*. Four-month-old rats were adrenalectomized and maintained with 1% NaCl, 1% glucose in the drinking water. Three days after adrenalectomy, they were paired with normal males. At parturition, some were continued on salt and glucose, while others were given tap water to drink and injected with DCA in 2 ml sesame oil daily during lactation. The ability to lactate was measured by the growth and survival of the litter, reduced to 4 young, the growth of comparable litters of normal mothers served as controls. Salt and sugar therapy enabled adrenalectomized mothers to maintain normal pregnancies and undergo normal parturition, but in no case was lactation normal. Similarly, lactation was not normal in animals given 0.1 or 0.5 mg DCA daily. One mg DCA resulted in significantly improved lactation, with all litters, though underweight, surviving until weaning. Two mg DCA gave normal lactation. Nearly normal body weight and carbohydrate stores have been maintained in adrenalectomized rats with 1% salt solution or 0.5 mg DCA (Anderson and Herring, *Proc Soc Exp Biol & Med* 43:363, 1940). The present results show that salt and sugar or DCA (0.1, 0.5 mg) will not maintain lactation but larger doses of DCA (1.0, 2.0 mg) are effective.

Rate of elimination of sulfadiazine from the blood in the newborn FRANKLIN F SNYDER *Depts of Obstetrics and Anatomy, Harvard Medical School, Boston, Mass*. Sulfadiazine was found in the blood for a prolonged period in premature, newborn, and early suckling infant rabbits in contrast to adults, following subcutaneous injection of a standard dose, 0.5 gm/kg. Thus, the blood was negative in adults in less than 12 hr, while in premature animals of 30 days the blood contained 6 mg/100 cc 24 hr after injection. At 18 hr, the blood level in full term animals of 32 days was 14 mg, in suckling infants of 1 week it was 5 mg, and at 2 weeks or older the blood was negative. Much higher concentration of sulfadiazine was noted in the blood of the newborn than in that of adults despite uniform dosage. At one hour following injection, the blood level in adults averaged 22 mg while in prematures it was twice as great, averaging 47 mg, in the newborn at term it was 33 mg, in suckling animals at one week it was 33 mg, and at 4 weeks was 27 mg. At 6 hr after injection, the blood level in the newborn averaged 35 mg in contrast to 7 mg in adults. In all samples

obtained from 150 rabbits, determinations were made before and after hydrolysis using Marshall's method. The foregoing results are of particular interest in connection with the clinical observation of increased hazard for the child associated with sulfadiazine therapy at the time of birth or preceding it.

Ratio between tension and total electrical activity in human skeletal muscle. R. SNYDER (by invitation), C. F. S. FISHER (by invitation), and A. C. BURTON. *Dept. of Biophysics, Univ. of Western Ontario, London, Ontario, Canada.* Most electromyography has used needle electrodes and recorded action currents of local single muscle units. General opinion has been that since different units were out of phase, the total integrated electrical activity, recorded from surface electrodes at the end of the muscle, would not correlate well with total tension. This is an error in statistical theory, and we find, using the flexor muscles of the arm and rectifying the output of an electromyograph, that there is a reproducible relation between tension and output. With the upper arm vertical, the elbow supported, and forearm horizontal, increasing loads are hung on the wrist. The output increases with increasing load, with a tendency for the slope of the graph to increase at high loads. Resistance of electrodes is not a disturbing factor. With a constant load, the output remains constant until fatigue sets in, when the electrical activity steadily rises. The ratio of tension to electrical output (T/E) is very different in the flexor arm muscles of different individuals, being much greater where the muscle is larger and presumably 'trained'. The measurement of the ratio offers a way of following the development of muscles by training and after disease, and of studying the process of fatigue. A consistent theory would be that in training and in fatigue, the electrical output of the single units is relatively constant, while the tension exerted is variable.

Pressure responses of the cerebrospinal fluid to diffusion respiration and carbon dioxide inhalation. JOSEPH N. SPENCER (by invitation), ELI S. GOLDENSOHN (by invitation), RICHARD W. WHITEHEAD, ROBERT F. GROVER (by invitation) and WILLIAM B. DRAPER. *Dept. of Physiology and Pharmacology, Univ. of Colorado Medical Center, Denver, Colo.* Simultaneous observations on cerebrospinal fluid pressure, systemic arterial and venous blood pressures, and heart and respiratory rates were recorded continually from dogs by means of strain gauge manometers. Venous blood pH was determined at intervals. Observations were made during diffusion respiration and with various concentrations of CO in O₂ administered by inhalation under light thiopental sodium anesthesia. With diffusion respiration and the various concentrations of carbon dioxide administered, the cerebrospinal

fluid pressure was seen to rise consistently to at least twice the control value, and to an average of 3½ times the control value. The maximum elevation is frequently observed within 10 minutes. During diffusion respiration, cerebrospinal fluid pressure rose slowly to 3½ times the control value after about 15 minutes. The pressure then declined from its peak but remained elevated. During inhalation of 40% CO₂ in O₂, the maximum rise in cerebrospinal fluid pressure was usually reached in 5 minutes and rose to 4½ times the control pressure. Changes in heart rate, respiration, and arterial pulse pressure were reflected in the cerebrospinal fluid pulse waves. However, neither these factors nor variations in arterial blood pressure showed close correlation with the observed rise in cerebrospinal fluid pressure. Studies on the effects of inhalation of 10, 20 and 30% CO₂ in O₂ will be reported.

Spectral deviations found in hemolyzed erythrocytes of rabbits fed a purified diet. S. S. SPICER, J. G. WOOLEY, and ARIEL M. CLARK (introduced by WILLIAM J. BOWEN). *Experimental Biology and Medicine Inst., National Institutes of Health, Bethesda, Md.* Rabbits maintained on a purified diet containing leached alcohol extracted casein, sucrose, Wesson oil, cellophane, minerals and pure vitamins have survived for a period of months to years. Some of these animals have shown an unusually dark color in the suspension of their washed red cells. Below 5800 Å, the absorption spectra of hemolysates from purified diet rabbits appeared normal. However, the 1/20 dilution of washed red cells of these rabbits in saponin buffer revealed abnormally high absorption between about 5900 and 6500 Å. This absorption was evident in the oxygenated hemolysate whether buffer of pH 6.2, 7.9, or 9.0 was used. Subtracting the mean molar (equivalent) extinction coefficient of hemolysates (pH 7.4) from several stock diet rabbits from that of the purified diet animals showed a maximum at 6200 Å in the oxygenated and 6150 Å in the CO treated solution. The optical density of the CO derivative exceeded that of the oxy form by about 40%. In hemolysates of the rabbits fed purified diet, when the hemoglobin was converted to methemoglobin at pH 8.6 or to metcyanhemoglobin there was slightly increased density occurring uniformly without the presence of an absorption band between 5800 and 6500 Å. The band in the oxygenated hemolysate was noted spectroscopically in 6 of 16 animals maintained on purified diet and in none of 15 rabbits on the laboratory stock diet for 1 to 3 years.

Electroshock studies. (a) Convulsant effect of microwaves. (b) Changes of current during stimulation. E. A. SPIEGEL, P. H. WILSON (by invitation), and A. J. LEE (by invitation). *Dept. of Experimental Neurology, Temple Univ. School of Medicine.*

Philadelphia, Pa , and Traverse City State Hospital, Traverse City, Mich a) The convulsant effects of repeated rectangular microwaves were studied on guinea pigs using a generator with pulses of 5 to 40 microseconds at frequencies from 60 to 800 per second and Offner's brief stimulus apparatus with pulses from 50 microseconds upwards at frequencies of 60 and 120 per second. The electrodes were applied bitemporally on the intact skull. Generalized epileptiform convulsions outlasting the stimulating current could be produced at a minimum duration of the individual pulses of 10 microseconds. Quantity-duration curves for the component pulses (abscissa msec, ordinate microcoulombs) obtained with Offner's stimulator (120/sec) showed that the necessary pulse Q's decrease as the total duration of the stimulation is increased from 0.1 second to 1.0 second and also as the duration of each pulse is decreased from 0.5 msec to about 0.05 msec. Temporal summation at this frequency apparently is sufficient to reach the convulsive threshold even when relatively few neurones are stimulated with each pulse, thus decreasing the possibility of supramaximal stimulation of some of the neurones.

(b) Cathoderay oscillograph records of voltage and current during stimulations with 60 cycle A C or halfwave rectified A C revealed a definite (up to 40%), regionally unspecific increase of current within the first 0.1 second. The decrease of resistance appears also on subthreshold stimulation. It is still marked 10 minutes after cessation of stimulation. The resistance to a large extent depends on the voltage applied, it is considerably lower with high than with low voltage.

Hemorrhagic diathesis in leukemia MARYLOO SPOONER (introduced by W J MEEK) *Dept of Physiology, Univ of Wisconsin Medical School, Madison, Wis*. Few studies concerning the cause of the hemorrhagic tendency in leukemia have appeared in the literature. A group of tests including coagulation time, clot retraction, prothrombin time, antithrombin titer, bleeding time, capillary fragility test, vitamin C levels of blood and plasma, and fluorescein test for capillary permeability was run on 33 patients with clinical diagnoses of various types of leukemia. Patients with Hodgkin's disease and lympho sarcoma were used as controls making a total of 50 patients. An attempt was made to correlate the findings with the presence of hemorrhagic signs. Results show that a correlation does not necessarily exist between positive laboratory data and the presence of hemorrhagic signs. In the group of patients with acute leukemia, there was a better correlation between positive laboratory data and clinical evidence of hemorrhage. Increased capillary fragility did not correlate with increased capillary permeability as determined by the fluorescein test. Lower vitamin-C

levels were found in the control group, which rarely showed hemorrhagic signs, than in the leukemic group which had a higher incidence of hemorrhagic signs. The data do not indicate whether or not hemorrhages might occur at some future time. As in other laboratory tests, a series of the same determination or a group of different determinations will yield more information than a single test.

Changes in blood pressure and renal function in hypertensive dogs following abscess production J STAMLER (by invitation), S ROBBARD and L N KATZ *Cardiovascular Dept, Medical Research Inst, Michael Reese Hospital, Chicago, Ill*. The production of an abscess in hypertensive dogs leads to a fall in blood pressure which usually begins within 24-48 hr of the tissue injury and persists for periods up to 3 weeks. This fall in blood pressure was studied in 9 dogs, it occurred when either subcutaneous tissue implantation or intramuscular carbon tetrachloride injection was used to incite abscess. As part of an extensive project investigating the mechanism of this phenomenon, renal clearance studies were done on these dogs prior to and following abscess production. These studies showed that abscess formation is also associated with a significant increase in renal blood flow, which usually begins within 24-48 hr and persists for as long as three weeks. This was more marked and prolonged in those dogs showing a greater, more sustained blood pressure fall. The increase in renal blood flow was not always synchronous with the fall in blood pressure. No significant changes in glomerular filtration rate were noted, the filtration fraction was decreased, renal vascular resistance was significantly lowered. The data suggest that the fall in blood pressure after abscess production may not be causally related to the increased renal blood flow (relief of renal ischemia) observed in these hypertensive dogs.

Further direct experiments on the relation between ballistocardiograms and systolic velocity curves ISAAC STARR, R L MAYOCK (by invitation) and O HORWITZ (by invitation) *Depts of Therapeutic Research and Medicine, Univ of Pennsylvania, Philadelphia, Penna*. We have continued the experiments of the type reported at the last meeting. Using cadavera lying on the ballistocardiograph at necropsy, fluid has been injected into the aorta alone, the pulmonary artery alone, and into both together. The amount of the injection was optically recorded at each instant. Aortic blood pressure was secured by a Hamilton manometer in the later experiments, and a normal diastolic pressure was attained by connecting a pressure bottle with a femoral artery. 'Normal' injections produced normal pressure pulse waves. We have secured good records of about 100 'systoles' in 6 cadavera. The deflection of the ballistocardiogram

is caused by the acceleration of the injected fluid and not by its velocity per se. The contour of the ballistic record follows that of the calculated curve of acceleration, lagging a little behind it. The 'J'-wave follows the contour of the first part of the acceleration curve with a fidelity which has surprised us, the latter part of the acceleration curve is not so accurately reflected in the ballistocardiogram unless the initial impacts are very small. Evidently after-vibrations from large initial impacts distort the latter part of the curve in more 'normal' records. In these experiments the 'I'-wave was smaller than is found during life, probably because the shape of the cannulae used did not reproduce the movement of blood within the heart during systole. For a given acceleration fluid injected into the pulmonary artery causes less initial deflection of the ballistocardiogram than fluid injected into the aorta.

Interrelation of effects of intraarterial injections of histamine and acetylcholine on gastric secretion. GEORGE W STAVRAKY *Dept of Physiology, Faculty of Medicine, Univ of Western Ontario, London, Canada*. As previously reported, acetylcholine injected into a quiescent stomach through the gastrosplenic artery causes an alkaline secretion which is free from pepsin (G M Morton and G W Stavrazy, *Federation Proc* 7: 82, 1948). Similar intraarterial injections of histamine in 1/300,000 dilution (100-200 cc/hr — 17 kg dog) are found to evoke a secretion of highly acid gastric juice of low digestive power. More concentrated solutions of histamine inhibit the secretion of hydrochloric acid. Addition of acetylcholine (1/100,000 concentration) to the solution of histamine lowers the acidity of the gastric juice but markedly activates the secretion of pepsin. Also, if acetylcholine is injected before histamine (causing an alkaline secretion without pepsin) a subsequent injection of histamine evokes a reduced secretion of acid but the gastric juice secreted in response to histamine now contains large quantities of pepsin. When atropine is injected before a combined administration of acetylcholine and histamine, it precludes the secretion of pepsin. However, interposed between the injections of acetylcholine and histamine, atropine does not prevent histamine from causing a secretion of gastric juice of high digestive power despite the fact that before atropinization acetylcholine caused a secretion which contained no pepsin. The results of these experiments seem to warrant the conclusion that a preexisting or combined cholinergic stimulation of the glandular elements of the gastric mucosa is necessary in order that histamine may cause a secretion of pepsin.

Pressure and activity recordings in the pylorus and rectum of man. F R STUEGGEND and W C CLARK (by invitation) *Dept of Physiology, Univ*

of Illinois, Urbana, Ill. By means of a pressure recording pick-up, consisting of a small water capsule at the end of a rubber catheter connected to an electronic amplifier, a continuous record of pressure changes can be made in various locations along the gastro-intestinal tract. In preliminary observations it was noted that there were very obvious differences in pressure and activity when the water capsule was believed to be passing from the stomach through the Pyloric Sphincter region and on into the small intestine. That these changes in activity and pressure recordings are consistent has been verified in experiments on 4 different individuals. Furthermore that this change in activity and pressure is found only in the Pyloric Sphincter region is confirmed by X-ray examinations. The actual pressure in the Pyloric region was 5-10 cm of water higher than on either the stomach or intestinal side of the sphincter area and the activity showed a tonic rhythm of 11 contractions per minute, an observation very different from that recorded in the stomach or intestine. When comparative studies of pressure and activity were made between the rectum and sigmoid colon, differences were also recorded.

Effect of coffee on the growth of white rats. ARTHUR H STEINHAUS and AARON SPITZER (by invitation) *George Williams College Laby for Physiologic Research in Physical Education, Chicago, Ill*. A coffee infusion interfered markedly with the growth of white rats when this was added to a milk diet fortified with iron and copper. Rats fed the fortified milk plus coffee infusion from the time of weaning averaged a gain of 49 gm in body weight in 9 weeks. Litter mates consuming identical quantities of milk plus tap water or milk plus 5% tannic acid in water, both equivalent to volume of coffee infusion, averaged a gain of 87 gm in the same period. When the diets of the 'coffee rats' and 'tannic acid' rats were switched at about 13 weeks of age, the direction of the growth curves was modified as expected, but not to as great an extent. This observation exonerates the tannic acid in coffee as the growth interfering factor. Studies now underway are designed to determine more accurately the 'coffee effect' at different ages and whether the observed growth failure is due 1) to the diversion of food to sustain a greater amount of spontaneous activity or 2) to some interference with its utilization.

Metabolism of pigeons in extreme cold. E STRFICHLER (by invitation), D B HACHEL (by invitation), W LEFISCHMAN and G L BULGER (by invitation) *Physiology Section, Medical Division, Army Chemical Center, Md*. The ability of fasting pigeons to survive up to 75 hr in extreme cold (-35°C) has been demonstrated (Hatch et al *Science* 107: 171, 1948). Further studies have been carried out to elucidate the metabolic factors

involved in this long survival time. The metabolic rates of pigeons weighing between 275 and 625 gm have been studied by means of an apparatus consisting of a desiccator jar of known volume containing a CO_2 absorber. The metabolic rate is estimated simply by determining the change in O_2 content of this chamber. At room temperature (24°C) the range for the basal metabolic rate is from 105–125 C/kg/24 hr. This rises to about 375 C/kg/24 hrs after 4 hr at -40°C , and varies between 300 and 500 C/kg/24 hr until the terminal drop in body temperature. Blood glucose remains within the normal range up to 72 hr, although the liver glycogen is almost depleted by the end of 24 hr.

Effect of cold adaptation on highest and lowest temperatures at which turtle heart continues beating. D. E. STULLKEN (by invitation), F. M. WHITE (by invitation) and W. A. HIESTAND *Laby of Animal Physiology, Purdue Univ., Lafayette, Ind.* Turtles were kept at 4°C as long as 10 weeks to allow 'cold adaptation'. The hearts of these turtles were placed in Ringer solution with 'control' hearts of non-cold adapted turtles. The temperature of the Ringer bath was slowly lowered and the temperatures at which the beating ceased was recorded. After both hearts had stopped beating at the lower of the two temperatures the bath was then heated and the temperature raised slowly until both hearts resumed beating and continued until each stopped at its respective high temperature. The results were as follows. With falling temperature the cold adapted hearts stopped beating at an average temperature of 11.3°C (av. of 8 hearts) while the non-cold adapted hearts stopped at an average temperature of 10.3°C (av. of 8 hearts). With rising temperatures the cold adapted hearts stopped at an average temperature of 38.9°C (av. of same 8 hearts) while the non-cold adapted hearts failed at 36.2°C (av. of same 8 hearts). Evidence shown by the cardiograms indicates that the sinus tissue is apparently affected by cold adaptation more than the myocardium. It is surprising that the cold adapted heart failed at a higher temperature than did the non-cold adapted heart with falling temperatures. Also paradoxically the cold adapted heart continued beating at a higher temperature than did the non-cold adapted heart with rising temperatures.

Centers governing temperature selection and the frequency response to temperature in the brain of trout. CHARLOTTE SULLIVAN (by invitation) and KENNETH C. FISHER *Univ. of Toronto, Toronto, Canada.* Trout in a gradient of temperature normally remain at, that is, select, a comparatively narrow range of the temperatures available. This response to temperature disappears when lesions are made in the forebrain of these organisms

but not when the dorsal portion of the cerebellum is destroyed. The frequency with which spontaneous movements occur in trout changes with temperature in a complex but reproducible manner. The general nature of this response is unaffected by damage to the forebrain but may be completely changed by destroying the dorsal part of the cerebellum.

Effect of posterior pituitary extract on man. F. SUNAHARA (by invitation), D. DUNCANSON (by invitation) and O. G. Edholm *Dept. of Physiology, Univ. of Western Ontario, London, Canada.* Forearm blood flow was measured before and after the intravenous injection of 4 units of histamine-free posterior pituitary extract into healthy male volunteers. Measurement of cutaneous blood volume was made with a Millikan oximeter ear piece. Immediately following the injection, the subjects' faces become ashen in color, the pallor persists for approximately 60 minutes. The oximeter readings on the ear showed a definite diminution in ear blood volume, but these readings returned to normal before normal color returned to the face. The forearm flow shows a slight increase immediately after the injection and thereafter is within normal limits. The subjects complained of nausea and abdominal discomfort and a desire to defecate. In several cases there was slight headache. These symptoms and the appearance of the subject are strikingly similar to those observed after fainting as a result of haemorrhage.

Effects of low environmental atmospheric pressure on the blood of turtles. LOUIS A. SUSCA (introduced by CHARLES G. WILBER) *Biological Laboratory, Fordham University, New York City.* Susca and Wilber (1948) reported changes in the cholesterol content of the blood of turtles of the variety *Pseudemys* sp. after subjecting them to pressures equivalent to various altitudes. Further pressure studies indicate that changes occur also in the glucose and phospholipid content of the

	CHOLESTEROL (PREVIOUS REPORT)	GLUCOSE	PHOSPHO- LIPID
Normal	38.2	51.8	14.4
18,000	108.5	110.2	14.0
33,000	118.5	129.4	21.8
48,000	87.2	219.6	12.6
64,000	70.1	188.2	50.9
90,000	49.2	205.6	9.1

blood of turtles. Estimations for glucose in the blood, using the Somogyi filtrate, were made for each of 10 untreated animals, and also, for 10 turtles subjected individually to pressures equivalent to altitudes of 18,000, 33,000, 48,000, 64,000, and 90,000 ft respectively. Estimations for the phospholipid content of the blood of turtles similarly treated also were made. The accompanying ta-

ble gives the mean value, in mg/100 cc of blood, for each of the substances estimated. Each value represents the mean of 10 readings, each of which is for the blood of a different animal.

Considerable variation occurs at different pressures, but changes within a single group of 10 animals are of the same order of magnitude. Emphasis in the changes is noted at pressures equivalent to altitudes of 33,000 and 48,000 ft respectively.

Effects of various concentrations of potassium cyanide on *Pelomyxa carolinensis* LOUIS A. SUSCA (by invitation) and CHARLES G. WILBER *Biological Lab., Fordham Univ., New York City*. A detailed study of the effects of 0.01M, 0.05M and 0.5M KCN on *Pelomyxa carolinensis* indicates that the cellular structures of the amoeboid organism are affected. Changes in the number, size, and shape of nuclei occur after the organisms are placed in the various solutions for more than 24 hr. In a 0.01M solution, the large number of nuclei characteristic of the organism is not affected, in a 0.05M solution, very few nuclei appear, in a 0.5M solution, a very small number of nuclei is observed. Sizes of the nuclei vary from 12 micra to 14 micra in diameter in organisms placed in 0.5M KCN, to 24 micra to 28 micra in organisms placed in 0.01M KCN. In 0.01M KCN, nuclei are spherical or elongated in shape, in 0.05M KCN, nuclei are ellipsoidal in shape, in 0.5M KCN, nuclei are either spherical or elongated in shape. The number of contractile vacuoles is largest in organisms placed in 0.5M KCN. Many contractile vacuoles are observed in organisms placed in 0.01M KCN, and very few are noted in organisms placed in 0.05M KCN. The distribution and spherical shape of refractive bodies in the organisms are not affected by any of the solutions. Food vacuoles form at frequent intervals in organisms from each solution, but fewest are formed in organisms placed in 0.5M KCN. The bipyramidal and truncated crystals are 3 micra in width in organisms placed in 0.01M KCN, mostly 1.5 micra in width in 0.05M KCN, and 1.5 micra to 3 micra in width in 0.5M KCN.

Free amino acids in the plasma of Eck fistula, meat intoxicated, and hepatectomized dogs MURIEL H. SIEG (introduced by SMITH FREEMAN) *Dept. of Experimental Medicine, Northwestern Medical School, Chicago, Ill.* Sixteen free amino acids were measured in the plasma of fasting dogs by microbiological assays. Alanine and glycine were determined chemically. Normal ranges were established on series of 12 to 36 dogs for each of 13 amino acids. Following Eck fistula formation, 4 of 5 dogs showed an average reduction of 10 μ g. of free leucine/ml. of plasma. This decreased value remained within the previously established normal range. Twelve other amino acids showed no consistent changes. Five of 6 meat intoxicated Eck fistula dogs showed definitely increased plasma histidine

and arginine, 8 of 9 showed increased methionine and tyrosine. Five other meat-intoxicated Eck fistula dogs showed slightly elevated cystine and leucine levels. The remaining 6 amino acids studied varied inconsistently or not at all. Two normal dogs and 7 or 8 portal-obstructed dogs on the same horse meat diet did not show these changes. In a series of 15 dogs, during an 8 to 16 hr. period following hepatectomy, plasma methionine dropped markedly in 12, sometimes disappearing completely. These animals also showed a definite elevation of the histidine level. Tryptophan decreased in all of 8 dogs studied. Three out of 4 animals showed increased alanine and lysine. Determinations of glutamic acid in 5 dogs and glycine in 4 showed definite increases in plasma levels post-operatively in all animals. These changes were distinct from those of the control period during which the animals to be hepatectomized received by vein the amount of glucose to be given post-operatively.

Castration and the mobilization of nitrogen during fasting CLARA M. SZEGO and ABRAHAM WHITE *Dept. of Physiological Chemistry, School of Medicine, Univ. of California at Los Angeles, Los Angeles, Calif.* The mobilization of nitrogen from lymphoid tissue, liver and carcass of castrate male and female mice of the CBA strain was studied during a 48-hr. fast. Castration in both sexes inhibited the decline in the ratio of lymphoid tissue to body weight which normally accompanies the stress of total inanition. Loss of nitrogen from lymphoid tissue was concomitantly depressed. The composition of the liver tissue of fed castrate mice differed significantly from that of intact controls. Higher concentrations of liver lipids and greater liver weights were observed in the gonadectomized animals. Utilization of liver nitrogen during subsequent fasting, however, was unaffected by castration. The mechanism by which castration inhibits the fasting involution of lymphoid tissue is being investigated in relation to adrenocorticotrophic and gonadotrophic activity of the adeno-hypophysis.

Measurement of renal plasma flow in man by the slope method without urine analysis HALL S. TACKET (introduced by C. RILEY HOLT) *Divisions of Medicine and Physiology, Univ. of Tennessee, Memphis, Tenn.* The rate of disappearance from the plasma of a substance, previously administered by a single intravenous injection, represents the amount of that substance removed by the kidneys per unit time, assuming no extra renal loss. That rate, expressed as a fraction (S) of the total substance available for excretion, multiplied by the volume in which the total substance is distributed (V_d), gives the volume of fluid that contains the amount removed by the kidneys per unit time, or the renal clearance (C). Thus $C = V_d S$.

We have determined para-aminohippurate clearance by this method in 12 experiments on 10 patients with no evidence of renal impairment, comparing results with simultaneously measured urine clearances (Before colorimetric analysis, all plasma filtrates and diluted urines were hydrolyzed in 0.4N HCl at 97°F for 3½ hours to free PAH conjugated by the liver) Slope clearance based on the volume of distribution of PAH gave values that were consistently too high However, using empirically the volume of distribution of mannitol, the quotient of the slope clearance and the urine clearance averaged 0.91 with a range from 0.65 to 1.08 In 8 of the 12 experiments, the quotient averaged 1.005 with a range 0.95 to 1.08 The reason for the failure to obtain completely consistent results is not yet evident, but good correlation was observed more frequently than can be explained fortuitously We failed to find satisfactory correlation between the slope clearance and the urine clearance of mannitol The explanation for this discrepancy, likewise, is not yet apparent

Reabsorption of potassium by the kidney
ROBERT TARRILL and DONALD W SELDIN (introduced by DONALD H BARRON) *Dept of Internal Medicine, Yale Univ School of Medicine, New Haven, Conn* From a survey of the literature one may surmise that a ratio of the concentrations of urine potassium to serum potassium below one has not been reported Concentration ratios (U/P) below one would signify formation of renal tubular reabsorbate with a concentration of potassium greater than that of extracellular fluid Such concentration ratios were observed during the following conditions: water diuresis, glucose diuresis during ingestion of water, and during recovery from the shock of 'dolphine' intoxication When urine flows were 948 and 1008 cc/hour during water diuresis, in 2 normal subjects, urine potassium was 2.5 and 2.8 mEq/l per liter, and concentration ratios were both 0.68 During glucose diuresis and water ingestion, urine potassium was 1.3 mEq/l, concentration ratio was 0.38, and urine flow was 1462 cc/hour Such high rates of urine flow are not a necessary prerequisite for a concentration ratio below one A ratio of 0.84 and urine potassium of 3.3 mEq/l when the urine flow was only 135 cc/hour occurred in a patient sustained on fluids without potassium during recovery from peripheral vascular collapse Despite the capacity of the kidney to produce a urine with a concentration ratio below one, this is rarely found during the development of potassium deficiency in man Conditions affecting efficient reabsorption of potassium during low rates of urine formation have not been clearly defined, but probably include the state of hydration and metabolic factors

Repetitive studies of intra-arterial pressures after resection for coarctation of the aorta in man

BOWEN E TAYLOR (by invitation), O THERON CLAGETT (by invitation), HOWARD B BURCHELL and EARL H WOOD *Section on Physiology, Mayo Foundation, and the Division of Surgery, Mayo Clinic, Rochester, Minn* Continuous and simultaneous intraradial and intrafemoral arterial pressures and electrocardiographic data obtained from 17 patients before and after resection for coarctation of the aorta have indicated that, postoperatively, the cardiovascular dynamics were altered toward, but did not attain, normal values Additional studies have been carried out to determine whether or not additional changes occur over longer periods after operation In 10 patients studied preoperatively, radial and femoral arterial pressures averaged 199 systolic and 101 diastolic and 117 systolic and 84 diastolic, respectively During the studies conducted an average of 3 weeks after operation, radial and femoral arterial pressures averaged 158 systolic and 77 diastolic, and 128 systolic and 74 diastolic, respectively When these patients were again studied an average of 7 (3 to 11) months after operation, the radial arterial pressure had decreased on the average from the first postoperative study 16 ± 5 mm Hg systolic and 9 ± 3 mm Hg diastolic, although the average change in femoral systolic pressures was not significant The average femoral diastolic pressure decreased 5.2 ± 2.5 mm Hg Significant improvement in the femoral/radial systolic pressure ratio and the femoral/radial pulse pressure ratio probably indicate that the decrease in cephalic blood pressure was related to a continued improvement in the blood flow through the descending thoracic aorta Evidently, additional changes in the cardiovascular dynamics toward normal may continue over a period of months after resection for coarctation of the aorta

Relationships between the blood pressure increases in exercise, carbon dioxide inhalation and the cold pressor test
HENRY LONGSTREET TAYLOR, AUSTIN HENSCHEL, JOSEF BROZEK and ANCEL KEYS *Laby of Physiological Hygiene, Univ of Minnesota, Minneapolis, Minn* The blood pressure responses to 3 standardized situations which increase blood pressure were studied in 379 normotensive healthy males There were 159 subjects 18 to 26 years old and 220 men 45 to 54 years old The tests were rigidly standardized as to time of events, relation to meals and psychological atmosphere Blood pressures were recorded during a preliminary period with the subject supine The hand was then immersed in ice water for one minute Five minutes later, the subject breathed 6% carbon dioxide for 5 minutes After a 5-minute recovery period, the subject walked on a motor driven treadmill at 3 miles/hour and 5% grade Blood pressures were observed at frequent intervals during each test by the auscultatory method

The greatest increase above the control level in the systolic blood pressure in each test was used as an index of the response. The product moment correlations for the following pairs were all less than 0.2 in both age groups: work systolic blood pressure increment and the cold test increment, work systolic blood pressure increment and the CO₂ test increment and cold test systolic blood pressure increment and the CO₂ test increment. There was no relationship between the resting systolic blood pressure and the systolic blood pressure increment in work or in the CO₂ test but the correlation between the resting systolic blood pressure and the systolic blood pressure increment in the cold test were 0.52 in the younger and 0.44 in the older age group.

Anti-diuretic substance in the urine after fainting. N. B. G. TAYLOR (by invitation) and R. L. NOBLE, *Dept. of Medical Research, Collip Medical Research Lab., Univ. of Western Ontario, London, Canada.* The present study was made on 14 normal young adult human male subjects, 7 of whom fainted and 7 of whom did not faint. They were bled by venesection of amounts from 270 to 1250 cc. There is no correlation between amount of blood loss and fainting. Urine specimens were obtained, by voiding, before and after fainting. These were extracted by the method of Noble *et al.* (1939) and tested for anti-diuretic activity by the rat method of Burn (1937). It has been established that the urine secreted after a faint contains an anti-diuretic substance in readily detectable amounts. No anti-diuretic activity is found in urine from 1) normal subjects, engaged in routine duties about the laboratory (24-hour specimens), 2) experimental subjects before venesection, 3) experimental subjects after venesection, if they did not faint. Urine has also been obtained from 2 subjects who fainted spontaneously, i.e. psychic, not due to venesection, both these cases show anti-diuretic activity in the urine after the faint and not at other times. Evidence will be presented that the anti-diuretic substance found is the secretion of the posterior lobe of the pituitary gland.

Origin of renal vasoconstriction in tourniquet shock. R. D. TAYLOR and IRVINE H. PAGE, *Research Division and Bunts Institute of the Cleveland Clinic Foundation, Cleveland, Ohio.* We have previously reported on the renal vascular effects of application of tourniquets to the hind legs of dogs and concluded that the renal vasoconstriction which occurs is predominantly of humoral origin. The demonstrations of Trueta, Barclay *et al.*, impelled us to re-examine this conclusion. Observations were made in dogs in which afferent stimuli from the hind legs were blocked by section of the spinal cord at L₁. The data thus made available for comparison consist of observations on renal circulation after application of leg tourniquets in

1) normal dogs, 2) in dogs with the kidneys denervated and 3) in dogs with spinal cord section causing deafferentation. In contrast to normal dogs or dogs with denervated kidneys, dogs of the third group (deafferented) do not show significant changes in renal vascular resistance or urine flow either during the time the tourniquets are in place or after their removal. Consequently, we conclude that the primary stimulus to renal vasoconstriction during the onset of tourniquet shock is neurogenic and arises at the site of tourniquet application. The presence of renal vasoconstriction in dogs with denervated kidneys suggests that the ultimate effector mechanism of this vasoconstriction is partly humoral.

Postural reflexes in deafferented limbs of the cat. R. D. TEASDALL (by invitation) and G. W. STAVRAKY, *Dept. of Physiology, Faculty of Medicine, Univ. of Western Ontario, London, Canada.* Sensitization of spinal neurones to chemical stimulating agents and to impulses reaching them via pyramidal tracts was demonstrated by Draks and Stavrakys (*J. Neurophysiol.* 229:11, 1948) and by Teasdale and Stavrakys (*Federation Proc.* 7:123, 1948). The present study of postural reflexes carried out by means of moving picture recordings showed that these reflexes though present in intact cats are not as distinct as in decerebrate animals being modified by voluntary movements and by a tendency of the forelimbs to stay in partial flexion. Within 1-3 weeks after deafferentation of one limb by means of posterior root section, postural reflexes, as noted by Bremer (*Annales de Physiologie* 4:750, 1928), become very active and brisk. The responses are not only of the extensor type but also active flexion of limbs becomes prominent. Furthermore, in the supine position with labial cleft at 45° above the horizontal plane ('minimal attitudinal extensor position' of Magnus, *Lancet* 211:531 & 585, 1926) the deafferented forelimb assumes a flexed position while the intact paw is extended at the radio-carpal joint. Ventroflexion of the head causes extension of the deafferented forelimb but usual flexion of the intact limb. Similarly, placement of the animal in the prone ('minimal') position increases the extensor tone of the deafferented forelimb. It is felt that these are modified positional and attitudinal reflexes brought about by impulses from the labyrinth and neck proprioceptors acting on spinal neurones sensitized by deafferentation. A differential study of these reflexes is in progress.

Metabolism of rat testis in vitro. J. A. T. 111

than it does in the presence of glucose, whereas the mature gland exhibits a markedly diminished Q_{O_2} in the absence of glucose. These data may signify that a metabolic difference exists between the tubular and endocrine portions of the gland, since the adult organ contains a much larger proportion of functioning tubular tissue than does the immature one. To test this hypothesis, 11 adult rats (mean weight 287 gm) were rendered unilaterally cryptorchid. Between 23 and 28 days after transplantation of the right testis, when histological examination showed marked regression of the tubular system, Q_{O_2} and representative dry weight determinations were made on the transplanted glands (mean weight, 155 mg/100 gm of rat). The scrotal glands (mean weight, 495 mg/100 gm of rat) from the same rats were used as controls. The results were as follows:

	Q_{O_2}	
	No substrate	200 mg p c glucose
Transplanted (11 rats, 11 vessels)	6.24 S.E. \pm 0.14	5.36 S.E. \pm 0.20
Control (5 rats, 13 vessels)	3.95 S.E. \pm 0.12	6.78 S.E. \pm 0.12

It is suggested that the tubular and interstitial components of adult testis may be differentiated by the metabolism of the surviving tissue as described herein.

Reorganization of sensory function in amputation stumps two-point discrimination HANS-LUKAS TEUBER (by invitation), HOWARD P. KRIEGER (by invitation) and MORRIS B. BENDER *Psychophysiological Laboratory, Dept. of Neurology, New York Univ. College of Medicine, New York City*. Thresholds of tactile discrimination of two points, simultaneously applied, were obtained in 36 men with unilateral amputations above the knee. All measurements were made with a touch compass applied to the skin of the stump and to homologous areas of the sound limb. Longitudinal thresholds were obtained by placing the compass along the proximo-distal axis of the limb, transverse thresholds by placing the points at right angles to this axis. The method of constant stimuli was used. The threshold was defined as that distance, between the two points of the compass, at which 50% of the responses were correct. Each threshold was determined by 140 trials. The thresholds for the stump were consistently below those obtained for homologous areas of the sound limb in 34 of the 36 subjects. The average transverse thresholds of the stump for all subjects were 24 mm compared to 36 mm on the sound limb. The average longitudinal thresholds were 29 mm on the stump and 42 mm on the sound limb. These differences were significant

at the 1% level of confidence. Similar, though smaller, differences were found between the stump and sound limb on testing proximal parts of the stump, the differences decreasing with a definite gradient as the hip was approached. There were no indications that superiority in two-point discrimination of the stump was due to the stretching or folding of the skin or concomitant distortion of the peripheral patterns of its innervation. The results are considered as presumptive evidence for central readjustments which impart to the stump some of the functional characteristics of the amputated limb.

Ascorbic acid and acclimatization of animals to cold environment M. THÉRIEN (by invitation) and L. P. DUGAL *Dépt. d'Acclimatation, Institut de Biologie Humaine, Univ. Laval, Québec, Canada*. It has been shown in our previous studies, that the white rats, which are able to synthesize ascorbic acid, do react to a long exposure to cold by an important increase in the ascorbic acid content of their tissues if adaptation to the new surrounding takes place, if not, the contrary occurs, namely a significant decrease in the content of that vitamin. Following that observation it was found that guinea-pigs, which are unable to synthesize ascorbic acid, need more and more of that vitamin as the temperature of the surrounding is being lowered. Among interesting topics that have been observed, it may be said that a) there is a retention of ascorbic acid in the cold, as indicated by analysis of the tissues and of the urine, b) a direct relation between ascorbic acid content of the adrenals and adaptability to low temperature, c) a preventive effect of ascorbic acid towards the normal hypertrophy of the adrenals in the cold.

Effect of vitamin deficiency, thyroid and adrenal hormones on oxidation enzymes of rat tissues SAMUEL R. TIPTON and FRANCES M. COLVIN (by invitation) *Dept. of Zoology and Entomology, Univ. of Tennessee, Knoxville, Tenn.* We have extended our earlier work on the relationship of vitamins, hormones and respiratory enzymes (succinic dehydrogenase and cytochrome oxidase) to include adenosinetriphosphatase and d-amino acid oxidase of rat liver and kidney. Albino rats maintained on casein-sucrose-vegetable oil plus the necessary supplement of commercial vitamin B factors have somewhat lower liver and kidney phosphatase and oxidase activities than do rats maintained on Rockland Rat pellets. Administration of desiccated thyroid or thyroxine for 10 to 20-day periods results in an increase in the activity of both enzymes. After adrenalectomy there is a somewhat larger decrease in amino acid oxidase. Treatment with lipo adrenal extract prevented the decrease in oxidase with a possibly significant rise in adenosinetriphosphatase. In vitamin B deficiency there is a small increase in liver phosphatase.

while that of kidney is not significantly altered. There is a decrease in the activity of amino acid oxidase in both tissues. When the B-deficient animals are treated with thyroid powder there is a marked rise in liver phosphatase, the rise being considerably greater than that in hyperthyroidism in rats on stock diet. Kidney phosphatase does not show this B-deficiency effect. The stimulation of oxidase activity by the thyroid powder is depressed by B deficiency.

Syringe oxygen cathode for measurement of oxygen tension in solution and in respiratory gases JULIAN M. TOBIAS *Dept. of Physiology and Toxicity Lab., Univ. of Chicago, Chicago, Ill.* If the ends of a syringe plunger be removed, one has a hollow tube which fits tightly into the syringe barrel. It is then a simple matter to insert an insulated platinum wire and a pencil-type calomel cell so that their tips just protrude from the end of the opened plunger. The plunger is then filled with paraffin or a cement. With leads from the other ends of the electrodes the platinum wire can be made a cathode 0.8 v. negative to the calomel anode. If a solution be aspirated into the syringe, using the electrode fitted plunger as the piston, the current which flows can be shown to be a linear function of the oxygen tension of the solution. Precision has been studied using Ringer's solution. In a 0.5 cc. volume one can measure a change of 0.019 cmm. of O_2 with a standard error of 0.0001 cmm. With the volume reduced to 0.05–0.02 cc., using a 1-cc. tuberculin syringe, sensitivity is extended to 0.0008 cmm. of O_2 with a standard error of 1.7–2.3%. The instrument can also be used for measuring pO_2 in gas mixtures by taking in a small amount of Ringer and some of the gas. After equilibration, the pO_2 of the Ringer is measured. The instrument is not as precise as the Haldane analyzer, and at pO_2 values from 185–75 mm. Hg it may differ from the Haldane by 3.2 mm. Hg, on the average. An analysis takes a few minutes. The instrument has not yet been successfully used with blood.

Coagulation decelerating action of hemophilic plasma on normal plasma L. M. TOCANTINS and R. T. CARROLL (by invitation) *Division of Hematology, Dept. of Medicine, Jefferson Medical College, Philadelphia, Penna.* A coagulation decelerating action of hemophilic plasma on normal plasma can be demonstrated if the bloods are collected swiftly, over suitable surfaces, centrifuged at high speed at 5°C. and the tests carried out in collodion or silicone coated tubes. This property of hemophilic plasma varies among hemophilic individuals

while it is being reduced in the lower layers. Dilution, aging and exposure to glass impair and eventually destroy clot decelerating and anticephalin activity. Normal plasma to which a lipid antithromboplastin (*Proc. Soc. Exptl. Biol. & Med.* 68: 110, 1948) has been added, acquires clot decelerating action on intact normal plasma, and behaves on dilution, and incubation with cephalin, like hemophilic plasma.

Effects of anticonvulsants upon properties of frog sciatic nerve J. E. P. TOMAN, M. D. GREENHALGH (by invitation), J. S. CARLSON (by invitation) and G. H. BJORKMAN (by invitation) *Depts. of Physiology and Pharmacology, Univ. of Utah, College of Medicine, Salt Lake City, Utah.* Frog sciatic nerves were treated for 5 or more hours with solutions of various hydantoins, acetylureas, barbiturates, and oxazolidine-2,4-diones in Ringer's solution at pH 7.3 and room temperature. Those compounds having a 5-phenyl group and no substitution in the 3-N position were effective in concentrations of 1 mM or less in preventing the following normal phenomena: prolonged lowering of threshold and production of 'ultrasupernormality' and 'rebound spikes' following supramaximal stimulation, lowering of threshold and appearance of repetitive discharges after immersion in neutral isotonic phosphate solution. These phenomena are similar in some respects to the convulsive behavior of pyramidal neurones described by Adrian and Moruzzi (*J. Physiol.* 97: 153, 1939). Diphenylhydantoin, the most effective compound studied ($ED_{50} = 0.04$ mM), had little effect on other aspects of excitability and responsiveness. In occasional experiments there was a moderate increase in threshold and an abolition of the positive overshoot following a conducted spike. Diphenylhydantoin had no consistent effect upon membrane time and space constants, membrane potential, action potential amplitude, conduction velocity and recovery following submaximal stimulation. Although diphenylhydantoin did not alter the depolarizing and conduction blocking effects of KCl, it prevented the increased exchange of radioactive K and Na ions in nerves pretreated with phosphate solution. The results indicate that some anticonvulsants may prevent abnormally induced hyperexcitability and high frequency discharges without impairing the normal function of neurones.

Effect of amino acids on neuro-muscular func-

tion characteristic for this disease, a maintenance of the amplitude of the action potential during indirect stimulation. To ascertain whether this beneficial effect was due to supplying an essential amino acid to muscle and nerve single amino acid deficiencies were established in mice to ascertain whether the deficient animal shows a myasthenia gravis-like impaired neuro-muscular function. Single amino acid deficiencies were established by administering crystalline amino acids, vitamins, fat, and carbohydrate as suggested in diets based on the work of Rose. Well fed mice, mice starved for 3 days, and mice kept on low rations of mixed food for 6 weeks served as controls. Mice starved for 3 days did not show an impaired neuro-muscular function as measured by electromyography. Mice kept on low food rations for 6 weeks showed some impairment of the neuro-muscular function. Mice on the diet containing the 10 essential amino acids showed a similar neuro-muscular function as mice on chronic starvation. Mice fed with diets containing 9 essential amino acids did not show an impaired neuro-muscular function after 2 weeks, showed some impairment after 4 weeks if the diet was lacking either leucine, or phenylalanine, lysine, histidine, threonine, methionine, and showed a marked impairment of neuro-muscular function after 6-8 weeks. Glutamic acid deficiency did not induce marked impairment of the neuro-muscular function.

Effect on the action potential of nerve and muscle of 2-methyl naphthoquinone. CLARA TORDA and HAROLD G. WOLFF. *New York Hospital and the Depts. of Medicine and Psychiatry, Cornell Univ. Medical College, New York City.* The effect of 2-methyl naphthoquinone on the function of nerve and muscle *in vitro* and *in vivo* was investigated to ascertain whether or not this potent inhibitor of choline acetylase impairs the function of nerve and muscle. In the presence of the naphthoquinone in concentrations of $1 \times 10^{-5}M$ the conduct on time of isolated nerve preparation increased and the area and amplitude of action potential decreased, the conduction time of nerve-muscle preparation (*in vitro* and *in vivo*) increased and the area and amplitude of action potential decreased. The muscle function on direct stimulation was not significantly impaired. Since naphthoquinone, in the concentrations used, is known to inhibit only choline acetylase, the dysfunction observed suggests that acetylcholine is necessary to maintain an optimal function of nerve, myoneural junction and the excitatory mechanism of muscle.

Gastric distention as a factor in the satiation of thirst. E. J. TOWBIN (introduced by E. F. ADOLPH). *Physiology Dept., Univ. of Rochester, Rochester, N. Y.* Since dogs stop drinking before any appreciable amount of water enters their

blood, this study was designed to determine some of the factors in the satiation of thirst. Thirsty dogs with esophageal fistulae were allowed to sham-drink at hourly intervals. In some experiments a stomach-balloon was inflated with water before the dogs drank. The volume sham-drunk was two to three times in excess of the real water deficit, and water introduced into the stomach reduced sham-drinking (corroborating Bellows, 1939). Water introduced into the stomach-balloon was equally effective in partially inhibiting sham-drinking. Supra-diaphragmatic vagotomy abolished this effect in 3 of 5 dogs. Inflation of the balloon increases the interval between sham-drinks when there is free access to water. In other experiments, intact dogs had free access to water. Each drink was automatically recorded. Following supra-diaphragmatic vagotomy (2 dogs) the mean drink-size increased, in one dog it almost doubled. Bilateral splanchnicotomy and sympathectomy (D3 through D12), in 2 dogs, was followed by a reduction in the mean drink-size. Subsequent to vagotomy the drink-size rose above control values. To date, attempts to pick up vagal afferent impulses stimulated by gastric distention have been inconclusive. It is believed that the filling of the stomach initiates afferent impulses which are partial cues in gauging the amount of water drunk. Either these impulses ascend the vagal trunk or the atony subsequent to vagotomy interferes with the initiation of 'distention' impulses.

Thrombin formation in presence of proteolytic enzymes and platelets. BURTON L. TRAVIS (introduced by JOHN H. FERGUSON). *Dept. of Physiology, Univ. of North Carolina, Chapel Hill, N. C.* The plasma protease (Loomis *et al.*, *Arch. Biochem.* 12, 1, 1947), said not to activate prothrombin, clot ovalated plasma or purified fibrinogen (Loomis and Seegers, *Science* 104, 461, 1946), has been found 1) to accelerate the clotting of recalcified plasma and 2) to speed up the rate of thrombin formation from purified prothrombin activated in the combined presence of calcium (optimal), 'accelerator globulin' (AcG), and washed platelet suspensions. Small amounts of crystalline pancreatic trypsin showed apparently analogous effects, but these, unlike the 'fibrinolysin' actions, were inhibited by crystalline trypsin-inhibitor from pancreas and by the 'antifibrinolysin' of Loomis. It is unlikely, therefore, that the fibrinolytic protease itself is responsible for these accelerator effects. There is no thrombin demonstrable in the 'fibrinolysin' and it shows no accelerator effect in the absence of platelets. It does not accelerate prothrombin activation by tissue thromboplastin in the presence or absence of AcG.

Metabolism of radioactive iodine in severe anoxic anoxia. L. VAN MIDDLESWORTH. *Dept. of Physiology, Univ. of Tennessee College of Medi-*

cine, Memphis, Tenn Several authors have shown that 40-50% reduction in oxygen consumption occurs in rats exposed to severe anoxic anoxia. This observation suggested the present investigation regarding the effect of anoxia on the thyroid activity as indicated by the alteration of radioactive iodine metabolism in anoxic rats. Fifteen young rats were placed on a low iodine diet and after 8 weeks 8 of the animals were exposed to 268 mm Hg barometric pressure (simulated 27,000 ft altitude) for 12 hours. All 15 of the rats were then injected with 10 microcuries of I^{131} and the anoxic rats were returned to the low barometric pressure. After 24 additional hours all of the animals were killed. The total I^{131} was determined in the thyroid gland, urine and a sample of plasma. The plasma I^{131} was fractionated by trichloroacetic acid into 'bound' and 'unbound' I^{131} . Significant findings include a pronounced reduction in 'protein bound' I^{131} in the plasma of the anoxic rats. The average values (expressed as percentage of plasma I^{131}) for the male animals were as follows: trichloroacetic acid filtrate of plasma of control rats, 26%, and of anoxic rats, 91%; trichloroacetic acid precipitate of the plasma of the control rats, 74%, and of the anoxic rats, 8%. In these experiments the I^{131} content of the thyroid glands and urine was not significantly altered by the hypoxia.

Trial of enterogastrone in Mann-Williamson dogs FRANK E VISSCHER and STANLEY C LYSTER (by invitation) *Labs of the Upjohn Company, Dept of Pharmacology & Endocrinology, Kalamazoo, Mich*. Two groups of six Mann-Williamson dogs were prepared, one group was injected intramuscularly five times weekly with 100 mg enterogastrone, the other group was uninjected. Animals were maintained on a diet of specially prepared food containing 25 parts ground pancreas, 25 parts ground liver, and with the remaining 50 parts consisting of commercial dog food, bread, cod liver oil and milk. One gram of ferrous sulfate was added per day to the diet of each dog. Four of 6 injected animals survived in good condition, one of two deceased animals died of a perforated ulcer, the average survival time of the living animals was 8 months and of the deceased animals, 9 months. Three of 6 uninjected animals survived in good condition, 2 of 3 deceased animals died of a perforated ulcer, the average survival time of the living animals was

PHILIP F WAGLEY (by invitation), IRWIN W SIZER, LOUIS K DIAMOND (by invitation) and FRED H ALLEN (by invitation) *Dept of Biology, Massachusetts Inst of Technology, and Blood Grouping Lab, Children's Medical Center, Boston, Mass*. Observations have been made of the serological, physical and biochemical effects of peroxidase plus H_2O_2 on human serum containing anti-Rh agglutinins of specificity anti-D and anti-C (anti-Rh₀ and anti-Rh¹) active in both saline and albumin. Peroxidase activity against antibodies was considered of interest because it has recently been shown to oxidize certain proteins (Sizer, *Fed Proc* 6, 202, 1947) and because of the presence of this enzyme in phagocytic cells and its apparent absence in lymphocytes. There was significant diminution in titer of anti-Rh agglutinins after exposure for 6 hours at 37°C (0.1 ml serum) with as little as 300 µg of peroxidase (having a P Z activity of 167) in the presence of H_2O_2 (0.3%). Hydrogen peroxide alone in concentrations as high as 0.3% had no observable effect. Manometric studies during the reaction revealed oxidation of serum proteins induced by the peroxidase- H_2O_2 system. Ultra-violet absorption spectra obtained before and after such inactivation of the antibodies by peroxidase showed changes in the absorption range of proteins. This suggests an oxidation by peroxidase of such constituent amino acids in protein as phenylalanine, tyrosine and tryptophane. These apparent peroxidase effects were not accounted for by any catalase present in the serum. Dialysis of serum against 0.85% saline at 6°C for 72 hours prior to incubation with peroxidase did not prevent the effects of the latter on the antibodies. Purified anti-Rh globulin showed comparable changes induced by peroxidase when studied by serological, ultra-violet and manometric techniques. However, these peroxidase effects are not considered specific because anti-A and anti-B activities of human serum were also decreased by incubation with peroxidase in the presence of H_2O_2 . Furthermore, serum containing no Rh antibody during exposure to peroxidase- H_2O_2 showed manometric evidence of oxidation and alteration in ultra violet absorption spectra of certain serum proteins.

flashes were 5 seconds or more apart. With a 2-second interval, the occurrence of a response created a bias against a response to the second flash. In a series of paired flashes of equal intensity separated by 2 seconds, with 10 seconds or more between successive pairs, responses occurred much less frequently to the second flash of the pair than to the first. This is true even of flashes following those flashes to which there had been no response, although the depression of sensitivity was less than when the first flash elicited a response. By varying the interval between flashes in the pairs, and by holding the intensity of the first flash constant while varying that of the second, it was found that within an interval up to about 1 second the effect of a subliminal flash summed with that of a flash following it. This was then followed by a condition of decreased sensitivity, the sensitivity reaching a minimum at 2 seconds (1 to 2 log units below normal) and returned to normal by 5 seconds. Following a flash that had elicited a response, there was loss of sensitivity which disappeared in about 5 seconds.

Renin concentration of the kidney in experimental renal hypertension. G. E. WAKERLIN, JOHN MARSHALL (by invitation), R. O. BURNS (by invitation) and BESS G. OSGOOD (by invitation). *Dept. of Physiology, Univ. of Illinois College of Medicine, Chicago, Ill.* During the past several years in our study of experimental renal hypertension we have determined the individual renin concentrations of 500 dog kidneys. The renin concentration of the normal dog kidney is relatively constant at approximately 2.0 dog (Goldblatt) units per gm. of fresh tissue. Renin disappears from the contralateral kidney 20 days after unilateral renal artery constriction, remains absent for at least 100 days, and returns to normal concentration 10 days following homolateral renal artery constriction. Significant atrophy of the constricted kidney, injection of certain hog renal extracts containing renin, and extreme morbidity from distemper and/or pneumonia favor the return or presence of renin in the contralateral kidney. Unilateral nephrectomy appears not to change the renin concentration of the remaining kidney. The renin concentration of the kidney is probably normal 1-3 months following renal artery constriction and is increased by injections of purified hog renin. Prolonged renal artery constriction (5-78 months) tends to decrease the renin concentration of the kidney and significant atrophy may enhance this tendency, whereas distemper and/or pneumonia favor an increased renin concentration. The renin concentration of the constricted kidney of experimental malignant hypertension varies from subnormal to supernormal, is not changed by injections of crude hog renal extracts containing renin but is increased by injections of purified hog renin. There was no correlation

between the renal renin concentration and the level of hypertension, chronic or malignant. Because of their limitations, these findings neither directly support nor oppose the renin-hypertension hypothesis of the pathogenesis of experimental renal hypertension.

Treatment and prophylaxis of experimental renal hypertension with renal extracts. G. E. WAKERLIN, J. E. BOURQUE (by invitation), JOHN MARSHALL (by invitation), R. O. BURNS (by invitation), BESS G. OSGOOD (by invitation) and LIONEL SCHOUR (by invitation). *Dept. of Physiology, Univ. of Illinois College of Medicine, Chicago, Ill.* We previously reported that crude hog renal extracts containing renin were highly effective in the treatment and prophylaxis of experimental renal hypertension in dogs. During the past four years we found various crude hog renal extracts and extract fractions to be variably and less effective. We now know that this difference is importantly due to the fact that our early extracts were prepared from hog renal cortex and our later less effective extracts were prepared from whole hog kidney. Thus all dogs of a group recently treated prophylactically with crude hog renal extract containing renin and prepared from cortex were protected against experimental renal hypertension, whereas no dogs treated with the same extract prepared from whole kidney were protected. Similarly, the same cortex extract was much more effective against experimental malignant hypertension than whole kidney extract. Purified hog renin (70 dog units/mg. N) was found to be effective in the treatment of renal hypertensive dogs. Purified hog renin was likewise effective in prophylaxis against hypertension but was definitely less effective than crude cortex extract in protecting against renal insufficiency and death following renal artery constriction to produce chronic hypertension. The results here reported are definitely favorable to antirenin as the mechanism of these therapeutic and prophylactic effects, but the question is still open and requires work now under way. The factor in renal medulla responsible for the inhibitory effect on the therapeutic and prophylactic potency of hog renal cortex and renin is also under investigation.

Enzymic reduction of the retinenes to the vitamins A. GEORGE WALD. *Biological Labs. of Harvard Univ., Cambridge, Mass.* Retinene, formed by the bleaching of the photosensitive pigment of rod vision rhodopsin, is subsequently converted to vitamin A₁ by a reaction in which reduced coenzyme (DPN-H₂) acts as coenzyme. Two hydrogen atoms are transferred from DPN-H₂ to retinene, reducing its aldehyde group to the primary alcohol group of vitamin A₁ (Wald and Hubbard, *J. Gen. Physiol.* Jan. 20, 1949). The system which performs this reduction has now been isolated and fractionated into its components: the coenzyme DPN-

H₂, the substrate, synthetic retinene₁ (vitamin A₁ aldehyde) prepared by the oxidation of crystalline vitamin A₁, and the apoenzyme, retinene₁ reductase, extracted with dilute salt solutions from homogenized frog or cattle retinas. The apoenzyme is non-dialyzable, is precipitated by half saturation of its solutions with ammonium sulfate, and is destroyed by heating to 100°C within 30 seconds. Its p_H optimum lies at about 6.5. The rods of freshwater fishes contain a parallel system which reduces retinene₂, formed by bleaching porphyropsin, to vitamin A₂. This also can be put together from its isolated components in solution: retinene₂ reductase, extracted with dilute salt solutions from homogenized retinas, DPN-H₂, and as substrate synthetic retinene₂ prepared by the oxidation of vitamin A₂. These enzyme systems bring a member of the vitamin B complex, the anti-pellagra factor nicotinamide contained in cozymase, into the chemistry of rod vision. They introduce also a novel vitamin relation—a B vitamin participating directly in the regeneration of the vitamins A.

Pancreatic secretion in response to mechanical stimulation of the duodenum. J. M. WALDRON (by invitation), J. L. THOMAS and L. P. TRACZ (by invitation). *Dept. of Physiology, Jefferson Medical College, Philadelphia, Penna.* Three healthy adult dogs were provided with gastric and duodenal tubulated fistulas of the type described by Thomas (*Proc. Soc. Exp. Biol. & Med.* 46: 260, 1941). The duodenal fistula was placed opposite the main pancreatic duct and therefore the pancreatic duct could be easily cannulated with a fine glass cannula. The accessory pancreatic duct had been severed and doubly ligated. After complete recovery from the operation a total of 78 experiments were made on these 3 dogs to determine the effect of mechanical stimulation of the duodenum on pancreatic secretion. In the principle type of experiment fasting juice was collected for 1 hour, then the dog was fed 200 gm. of Purina Dog Chiekers and pancreatic juice collected for 5 hours. In each dog experiments of this type were done with rubber tubes in the stomach and duodenum as the mechanical stimulus and without these tubes in place. Other experiments were performed on each dog to investigate the possibilities that increased HCl secretion or patent pylorus or specific properties of the rubber tubing accounted for our results. These experiments conclusively demonstrate that mere mechanical stimulation of the duodenum changes the rate of pancreatic secretion in the fasting animal usually increasing it. Furthermore the presence of mechanical stimuli in the duodenum alters the response of the pancreas to food.

Effect of temperature on the response of rat muscle to indirect repetitive stimulation. SURI-PARD M. WALKER. *Dept. of Physiology, Washing-*

ton Univ. School of Medicine, St. Louis, Mo. Isometric myograms were obtained from the triceps surae (in situ) of male rats under sodium barbital (300 mg/kg) anaesthesia. Electrograms were recorded simultaneously from the gastrocnemius. The muscle temperature was reduced by refrigeration (10°C) of the animals for 1 to 2 hours. At body temperature (36.5°C) the peak tension induced by double shocks is 200 to 220% of peak twitch tension. The peak of added tension resulting from the second shock increases from 140 to 160% of peak twitch tension as the interval between shocks is increased beyond the refractory period to the early portion of the falling phase of the first response. Reduction of the muscle temperature to 26°C induces a twitch with peak tension 180% and peak time 300% of normal. The peak tension produced by double shocks is only 133% of twitch tension in the cool muscle. The peak of tension added by a second response increases from 40 to 65% of twitch tension as the interval between shocks is increased beyond the refractory period to the peak time. The tension induced by tetanic stimulation at 125 shocks per sec. is slightly greater in warm muscle. Duration of the action potentials is prolonged in warm and in cool muscle by shocks repeated at short intervals. The results show that the cool muscle summates twitch tension less effectively than warm muscle both in double responses and in tetanic responses, although it shows a marked increase (180%) of twitch tension.

Effects of pancreatic duct ligation upon the action of secretin and pancreozymin in rabbits. C. C. WANG (by invitation), K. J. WANG (by invitation) and A. C. IYI. *Dept. of Clinical Science, Univ. of Illinois College of Medicine, Chicago, Ill.* Rabbits with pancreatic ducts ligated for periods ranging from a few hours to two weeks were used. The functional state of the pancreas was assessed by studying the response to secretin and pancreozymin and correlations were made with the histological picture. Within 24 hours, the volume response to a standard secretin stimulation was clearly decreased and the enzyme content was lowered. Histopathologically, there were protoplasmic changes in the acinar cells and the ducts became dilated. On the fourth day, the effect of pancreozymin began to disappear and the secretin effect was greatly reduced. The enzyme content of the juice was very low. The corresponding tissue sections showed the progressive degeneration of the parenchyma and an infiltration of fibrous tissue. The response to secretin continued to fall progressively as the period of ligation was lengthened. Finally, on the 14th day the parenchyma was mostly replaced by fibrous tissue and the secretin action was also gone. The secret juice obtained showed absence of amylase.

Formation of protein or other aggregates by

reactions linked in series DAVID F WAUGH *Dept of Biology, Massachusetts Inst of Technology, Cambridge, Mass* The intermolecular bonds formed during collision of two single molecules may not be sufficiently strong to afford stabilization against thermal disruption. The association of three or more molecules, either by simultaneous collision or by single molecules colliding with previously associated groups, may be stabilized by the simultaneous formation of several low energy bonds. Although similar bonds may be formed throughout, the reaction course may be examined by assuming two reactions the first of which is termed an initiating (active center forming) reaction and the second the augmentation reaction (elongation reaction in fibril formation). The order of the first reaction indicates the number of molecules necessary to initiate a stable aggregate. The second is expected to be pseudo-first order with respect to unit aggregating surface, i.e., the rate at which 1 cm^2 of surface augments will vary with the concentration of free protein. The total augmenting area of each locus of aggregation may increase with size thus introducing a further kinetic complication. Such considerations give differential equations which have been solved for first, an initiating reaction of order N followed by a pseudo-first order augmentation reaction assuming the aggregate rapidly approaches constant augmenting area, and second, an augmentation reaction alone in which predetermined numbers of active centers of initial size M_0 are introduced into solutions of protein and augment with increase in augmenting area. The general case of linked initiating and augmentation reactions with increase in augmenting area with size has been examined numerically.

Effect of increased renal venous pressure on renal function RENÉ WÉGRIA and (by invitation) WILLIAM D BLAKE, RICHARD P KEATING and HENRY P WARD *Dept of Medicine, Columbia Univ College of Physicians and Surgeons and Presbyterian Hospital, New York City* The effect of increased renal venous pressure on renal function was studied in anaesthetized dogs by means of clearance techniques. Renal function was measured separately and simultaneously in the two kidneys, but the pressure was raised in the left renal vein only, by means of a specially designed clamp. Moderate elevation of the left renal venous pressure from a normal value of around 100 mm saline up to 350 mm saline caused in that kidney a significant decrease in water and sodium excretion without any change in renal plasma flow, glomerular filtration rate, glucose Tm or diodrast Tm. The reduction in water and sodium excretion was due to an increase in the reabsorption rate of these substances by the renal tubule cells. This effect also occurred when the sodium load was low. Greater elevation of venous pressure (up to 550

mm saline) decreased renal blood flow and filtration rate, but there were insufficient results to state whether filtration fraction was significantly altered. The mechanism for the increased reabsorption of sodium and water ascribed to the increase in venous pressure and the implications of these results on the pathogenesis of the edema of cardiac failure will be discussed.

Effects of the 'hyperglycemic factor' found in insulin preparations H F WEISBERG (by invitation), R CAREN (by invitation), B HUDDLESTON (by invitation) and R LEVINE *Dept of Metabolic and Endocrine Research, Medical Research Inst, Michael Reese Hospital, Chicago, Ill* This study was undertaken to evaluate certain aspects of the action of the 'hyperglycemic factor' (H F) present in commercial insulin preparations. 1) Well-fed unanesthetized rabbits given 1-50 U/kg/hr of insulin intravenously over a 6-hour period, demonstrated the presence of H F in all cases. However the degree of effect bore no consistent relation to dosage. 2) Fasting (24 hrs) abolished or greatly reduced the tendency to hyperglycemia. 3) Subcutaneous injections of insulin into well-fed animals, in contrast to the intravenous route, resulted only in hypoglycemia. 4) During the hyperglycemic phases of alloxan action in dogs there was no detectable increase in the H F of serum from the pancreaticoduodenal vein, as measured in vitro by the method of Sutherland and Cori (*J Biol Chem* 172: 737, 1948). 5) The part played by the adrenal medulla in determining the degree of hyperglycemia will be discussed. No physiological significance can, as yet, be attributed to this factor, on the basis of our findings or those in the literature.

Chemical structure and the physiological properties of acetylcholine JOHN H WELSH *Biological Labs, Harvard Univ, Cambridge, Mass* As a working hypothesis to explain the reactions between acetylcholine (Ach) and cellular constituents it has been suggested that Ach acts as a co-enzyme. This requires postulating two classes of enzymes in order to account for the muscarinic and nicotinic actions of Ach. The nature and spatial arrangement of certain groups within the Ach molecule and the enzymes would determine, in part, which enzyme was activated. Pfeiffer (*Science*, 107: 94, 1948) has correlated the spatial relationships of possible 'prosthetic' groups in Ach and certain parasympathomimetic drugs with the muscarinic activities of these compounds. This study is an attempt to determine the properties of the Ach molecule responsible for nicotinic action. The physiological actions of certain simple quaternary ammonium ions on invertebrate nerve and muscle have been observed and it has been found that at least three methyl groups are necessary for maximal nicotinic action. The substitution of 3

ethyl groups for the methyls attached to the nitrogen of Ach produces an effective Ach blocking agent which is stable to insect cholinesterase. In instances where choline esters, tetramethylammonium ions and anti cholinesterases fail to produce excitation while triethylacetylcholine and tetraethylammonium ions excite, it is suggested that the level of active Ach within the tissue may be within the paralytic range and partial blocking of Ach may, in effect, reduce the level until it falls within the excitatory range.

A volumetric apparatus for studies of tissue metabolism. REIDAR WENNERSLAND (introduced by J. FENN) *Arctic Research Lab., Point Barrow, Alaska, and Dept. of Physiol., Stanford Univ., Calif.* A portable microrespirometer has been devised, which offers several advantages over the conventional Warburg type. These are: The volumetric principle, which allows a direct reading of the oxygen consumed, so that calibration of the respirometer vessels is unnecessary, less sensitivity to temperature changes, and a thermobarometer compensation for changes in barometric pressure and humidity. The measuring unit is compact, unbreakable and well suited for transport and field work. It is based on the same general principles as the respirometers worked out by Scholander. A V-shaped manometer and an oxygen chamber are drilled into a rectangular piece of plexiglass, (a material first introduced into microrespirometry by Scholander) and are connected to a respiration chamber of the Warburg vessel type. The second branch of the manometer is connected with a small thermobarometer bottle. The carbon dioxide produced is absorbed in alkali. The decrease in oxygen is indicated by the manometer. A stainless steel plunger is pushed into the oxygen chamber until the manometer is back to the level it had at start and at previous readings. The position of the plunger can be read with a dial indicator or by a simplified micrometer screw device and gives the oxygen consumed between the two readings, when the dimensions of the plunger are known. For a comparative study on tissue respiration by this and the Warburg method see abstract by Peiss and Wenersland.

decompression and anoxia. Following sudden decompression from sea level to 40,000 ft simulated altitude in O_2 , at which altitude the anoxia is insignificant, the slight blood pressure reduction is only of few seconds duration, after which both systolic and diastolic pressures are maintained at near control level while the animal remains at this altitude. The marked and sustained vasomotor change is observed only after sudden decompression to altitudes at which the animal is completely anoxic. We have confirmed the observation that the pulse pressure disappears after explosive decompression to altitudes above 60,000 ft. With relatively slow decompression to such altitudes, however, the pulse pressure is reduced but does not disappear. The systolic pressure may begin to recover during recompression when the animal is still at altitudes of complete anoxia, indicating a recovery from effects of sudden ambient pressure changes. The diastolic pressure recovery is slower and appears to be essentially a function of recovery from anoxia and very similar to records of recovery from 100% N_2 anoxia. This difference in recovery rates results in a temporary increase in pulse pressure above control level. Both systolic and diastolic pressures rise above predecompression levels towards the end of recompression but return to near control levels at end of recompression.

Renal dynamics and salt and water excretion in the dog following expansion of extracellular fluid. LAWRENCE G. WISSON, JR., W. PARKER ANSLOW, JR., LAWRENCE G. RAISZ, ALFRED A. BOLOVRY and MICHAEL LADD (introduced by HOMER W. SMITH) *Dept. of Physiology, New York Univ. College of Medicine, New York City.* Extracellular fluid volume in dogs was increased 5 to 10% of body weight by slow or rapid infusion of modified Loeb's solution and the increase sustained up to 9 hours by the intravenous replacement of NaCl, KCl and water as fast as the components were excreted. Filtration rate (CF), renal plasma flow ($CPAH$), filtration fraction (FF) and urine flow (V) showed a 3 phase response. During *Phase I*, $CPAH$, CF and V increased to peak values well above control values. At the rate of

then fell to a value slightly hypotonic to the blood shortly after the peak value of V was reached. If the control values were high, UCI decreased steadily to the hypotonic level. During Phase III, UCI rose until it attained a stable hypertonic level. In Phase III, renal dynamics, urine flow and urine concentration manifested a marked stability.

Renal tubular action of diuretics. II Effects of mercurial diuresis on glucose reabsorption. R. E. WESTON, J. GROSSMAN (by invitation), I. S. EDELMAN (by invitation), D. J. W. ESCHER (by invitation), L. LEITER (by invitation), and L. HELLMAN (by invitation). *Medical Division, Montefiore Hospital, New York City.* The tubular site—proximal and/or distal—at which mercurial diuretics act has never been precisely localized. Recent investigations have demonstrated that in man salyrgan produces not only decreased tubular reabsorption of electrolytes and water, but also significant depression of TM_{GH} , a renal function presumably limited to proximal tubular segments. Since it is well established that glucose reabsorption is limited to the proximal tubule, the effect of mercurial diuretics on maximal tubular capacity for glucose reabsorption (TM_G) was determined in human subjects without clinical renal disease. Preliminary experiments revealed that intravenous administration (2 cc.) of Mercuzanthin or Thiomerin (Disodium-N-(γ -carboxy methyl mercapto mercuri-B-methoxy) propyl camphoramate) immediately after several ten minute control periods generally resulted in a 40–80% decrease in TM_G , which coincided with maximal electrolyte and water diuresis. As diuresis diminished, TM_G returned toward normal. In these earlier experiments, concentrated glucose-mannitol aqueous solutions were infused, and the combined mercurial-osmotic diuresis produced significant decreases in serum electrolytes and extracellular fluid. To obviate this, infusions were prepared in normal saline. Because prolonged (90–150 minute) administration of glucose in saline has been reported to produce 20–30% decreases in TM_G in occasional subjects, in a second series of experiments, control and post-mercurial glucose TM 's were determined separately at 5–7 day intervals. In these shorter experiments, mercurials were administered prior to glucose infusion and produced similar depression of TM_G . It is concluded that in man mercurial diuretics depress a specific proximal tubular function.

Liberation of histamine by epinephrine. P. WHEELER (by invitation) and F. R. GOETZL. *Inst. of Medical Research, The Permanente Foundation, Oakland, Calif.* Recent reports indicate that in human beings an increase occurs in histamine content of blood plasma following intravenous administration of epinephrine. The observation was interpreted to indicate an ability of epinephrine to bring about liberation of histamine from

tissues. The present *in vivo* and *in vitro* experiments were performed using rabbit's blood. Histamine was assayed according to the method of Barsoum and Gaddum as modified by Code. In 25 *in vivo* experiments epinephrine in doses varying from 0.05 to 1.0 mg/kg was injected intravenously into anesthetized rabbits. Blood samples were obtained from the animals by heart puncture before and at 10 to 15 minute intervals after the injection for a period of 50 to 60 minutes. In blood samples thus obtained histamine was assayed and the leucocytes were counted. For the purpose of control similar experiments were performed in 10 animals which received intravenous injections of physiological saline solution instead of epinephrine. The results obtained from the *in vivo* experiments showed that intravenous injection of epinephrine causes a decrease in blood histamine and in the leucocyte count. In 37 *in vitro* experiments blood was obtained by heart puncture. Histamine was assayed in whole blood and in plasma after addition to the whole blood of equal volumes of epinephrine (0.001 and 0.1 mg/10 cc) and of saline solution, respectively. The results of the *in vitro* experiments showed that addition to whole blood of epinephrine is followed by an increase in plasma histamine, presumably due to liberation of histamine from leucocytes. The observations described are regarded to indicate that the decrease in blood histamine which, under the conditions of the experiments, followed intravenous injection of epinephrine into rabbits, was preceded by a shift of histamine from intracellular to extracellular compartments.

Development of seizure pattern by repetitive minimal cortical stimulation. J. A. WHELDON (by invitation) and A. VAN HARREVELD. *Kerechhoff Labs of the Biological Sciences, California Inst. of Technology, Pasadena, Calif.* Leño described a slowly spreading, transitory depression of the normal cortical activity which could be elicited by stimuli too weak to produce an afterdischarge. During this spreading depression he furthermore observed a cortical activity of a convulsive type. In the present experiments it was found that this convulsive activity is completely absent during the depression produced by the first stimulus after a long rest (1 hour). On repetition of the same stimulus at 5 to 10 minute intervals the convulsive activity developed and grew in intensity and duration. Also it was found that a stimulus of a strength and duration which initially was insufficient to produce an afterdischarge did so after repetition. Both afterdischarge and convulsive activity growing in intensity and duration with further repetition were in some experiments finally found to merge, producing an electroencephalogram typical of an electrically induced seizure. A rest of one hour was sufficient to restore the original situation.

in which a stimulus produced spreading depression without either afterdischarge or convulsive activity. After a wave of spreading depression had passed over the cortex the cortical activity was abnormal (bursts or continuous runs of medium to high potentials, 100–500 micro volts, slow, 2–5/sec waves) even if the stimulation produced neither afterdischarge nor convulsive activity.

The capacitance method for the study of cardiac activity WILLIAM V. WHITEHORN and EDWARD R. PERL (by invitation) *Dept of Physiology, Univ of Illinois College of Medicine, Chicago, Ill.* Studies of capacitance changes accompanying the cardiac cycle in the human have continued. Substitution of A C for D C amplification in the apparatus has increased stability and gain and simplified operation. Techniques and conditions for record taking have been standardized and the relative importance of technical factors determined. Further analysis of records (cardiodiagrams) in relation to simultaneously recorded electrical and mechanical cardiac events supports earlier conclusions that such records are directly related to cardiac volume changes and may provide an approximation of stroke volume. Comparisons of relative stroke volumes calculated from cardiograms of normal subjects under conditions of rest, exercise and performance of the Valsalva maneuver yield results in keeping with expected changes and provide evidence for the relative validity of the method. Absolute calibration of the instrument has been carried out by the introduction of spherical, saline filled balloons of known volume into the condenser field in positions approximating that of the heart. Results derived from such calibration curves cannot, however, be considered conclusively valid and comparison with simultaneous determinations by the direct Fick procedure are now in progress.

Action of dilute trypsin on muscle protoplasm (motion picture) FLOYD J. WIERCINSKI and BRIAN A. COOKSON (introduced by JOHN C. SCOTT) *Dept of Physiology, Hahnemann Medical College, and Dept of Zoology, Univ of Pennsylvania, Philadelphia, Penna.* Recent studies have indicated that the colloidal behavior of muscle protoplasm is similar to the colloidal behavior of blood. The clotting of muscle protoplasm (for example by free Ca ion) produces shortening. Inasmuch as dilute trypsin solutions act like thrombin in causing blood clotting, it was thought to be of interest to determine the effect of dilute trypsin on muscle protoplasm. The trypsin preparation used contained 50% of a magnesium salt, the concentrations reported here are based on the trypsin content. The microinjection of a dilution of 1:1000 and 1:2000 in a calcium-free Ringer solution caused a dramatic clotting of the sarcoplasm but the sarcolemma was unaffected. The interior protoplasm

contracted so sharply that it broke into pieces. A somewhat weaker effect is produced by the injection of a 1:10,000 solution. The myofibrils in the interior of the fiber were seen to break in several places along the longitudinal axis. The cortical region just under the sarcolemma appeared to be unaffected by this concentration of trypsin. A 1:100,000 dilution of trypsin upon injection into the muscle fiber caused very little effect but there was a slight contraction.

Testing the validity of ashing and digestion procedures by isotope dilution WALTER S. WILDE *Dept of Physiology, Tulane University, New Orleans, La.* We analyze for phosphate in the phosphoprotein-nucleic acid residue of Schmidt and Thannhauser. The sulfuric-nitric acid digest (Fiske and Subbarow, *J Biol Chem* 66:377) of intestinal mucosa from the rabbit is analyzed colorimetrically. The procedure is tested by applying the expression, $P_d^*/P_d = P_{Mg}^*/P_{Mg}$. We call the known tracer mixed with the phosphate residue before digesting P_d^* . After digestion an aliquot is neutralized and precipitated as $MgNH_4PO_4$. This is washed thoroughly, redissolved in dilute acid, and analyzed for tracer and for phosphate (colorimetric). This gives the ratio P_{Mg}^*/P_{Mg} . We then calculate for P_d which is compared to a direct colorimetric analysis of another aliquot of the acid digest. Three runs from a common pool are tabulated.

P_d^*	P_{Mg}^*	P_{Mg}	CALC	P_d FOUND
c/sec	c/sec	mg	mg	mg
273	227	0.265	0.318	0.320
204	185	0.294	0.324	0.310
41	28	0.209	0.303	0.282

Although absolute loss occurs with the magnesium ppt. the tracer and non-tracer are lost proportionately so that their ratio remains unchanged and available for a valid calculation. The agreement between the value calculated and that found indicates there is no volatilization heat loss, that the presence of possible chemical interfering substances in the acid digest gives colorimetric results no different from those for the simpler solution of dissolved magnesium ppt., that pyrophosphates, if they do form, are later hydrolyzed.

Toxicity studies on antioxidants—butylated hydroxyanisole and hydroquinone O. H. M. WILDER and H. R. KRAYBILL (introduced by A. J. CARLSON) *American Meat Inst. Foundation, Univ of Chicago, Chicago, Ill.* Butylated hydroxyanisole (BHA) and hydroquinone (HQ) are both excellent antioxidants for use in animal fats. Toxicity studies have been made on BHA and on a mixture of BHA and HQ, using rats, to determine their LD-50s and to see if their long continued ingestion would have

any harmful effect on the animals Six % of lard containing up to 2% of BHA was fed in a good basal ration for periods up to 21 months from weaning. No significant differences were observed in weight gains from weaning time between the controls and any of those getting the antioxidant, nor were there any differences in reproduction and growth of young. Another group of rats was started as soon after weaning as they would consume the ration and fed for 6 months at levels of BHA up to 2% of the ration. The only observed effect was a retarded weight gain at the higher levels. No effect was observed upon autopsy in any of the rats, and histological examination revealed no pathological conditions that could be attributed to the antioxidant at any level of feeding. A mixture of 80 parts BHA, 12 parts HQ, and 8 parts citric acid fed at levels of 0.3 and 2.0% of the ration has shown no effect during the growing period. The LD-50 of BHA dissolved in corn oil is 4.1 gm/kg body weight in the rat. In a water emulsion, on a fasted rat, it is in excess of 5.0 gm/kg body weight.

Pressure and flow of blood distal to a point of reduced arterial bore. ARNOLD H. WILLIAMS (introduced by HENRY A. SCHROEDER) *Dept of Internal Medicine, and the Oscar Johnson Inst., Washington Univ. School of Medicine, and Barnes Hospital, St. Louis, Mo.* The decreases of pressure and flow of blood distal to a point of reduced arterial caliber are of considerable physiological importance. Heretofore studies of these hemodynamic changes, produced by external compression of an artery, have been complicated by obstruction of venous return or have been done without exclusion of collateral circulation. For this reason the changes of the pressure and flow of blood were studied in the brachial artery, distal to an adjustable clamp, in the isolated forelimb of five dogs. Blood was supplied from the animal but a perfusion reservoir was connected to the circuit to obtain pressure-flow curves. In one instance oxygen tension of the muscle was measured simultaneously. Short or prolonged arterial constrictions (up to 25 minutes) did not produce any consistent relationship between the reduction of pressure and the reduction of flow. Neither was this relationship found at the end of 15-second perfusions of the constricted artery. The calculated percentile decrease of flow was not always greater at lower perfusion pressures. Thus arterial constriction produced no consistent change of arteriolar resistance distal to the constriction.

Hepatic vital staining and dye excretion in CCl₄-treated mice. W. LANE WILLIAMS *Dept of Anatomy, Univ of Minnesota, Minneapolis, Minn.* Hepatotoxic centrilobular injury was produced by CCl₄ and concomitant hepatic reactions to the following were studied: 1) two acid diazo dyes, trypan blue (Color Index 477) and chlorazol fast

pink (C I 353), 2) the triphenylmethane fluoran dye (also a xanthene fluoran), rose bengal (C I 779), and 3) the sulfonated triphenylmethane dye, isamine blue (C I 710). Dyes were injected subcutaneously or intraperitoneally as 0.5 to 1% saline or aqueous solutions in amounts of 0.1 to 0.4 cc. The azo dyes were excreted in normal and CCl₄-treated mice by the kidney, Rose Bengal by the liver, isamine blue, by liver and kidney. The azo's and isamine blue were present in macrophages as segregated granules. Rose Bengal was not deposited in macrophages in such a fashion and did not appear in such cells in an observable quantity. The azo's and isamine blue clearly stained the cytoplasm of damaged cells and remained in such cells until lysis ensued. The former dyes were definitely aggregated into large particles during actual necrosis, but the latter did not clearly undergo such a striking alteration. In contrast to the above, Rose Bengal stained the cytoplasm of all hepatic parenchymal cells. At 4-6 hours after intraperitoneal injection normal cells were clear of this dye, while cells in the centrilobular area of damage retained the dye for 8-14 hours depending on the interval (24-48 hours) subsequent to treatment with the hepatotoxic hydrocarbon.

Metabolism of the rat spinal cord functioning in isolation. R. D. TSCHIRGI (by invitation), R. W. GERARD, H. JENNERICK (by invitation), L. L. BOYARSKY (by invitation), J. Z. HEARON (by invitation) *Dept of Physiology, Univ of Chicago, Chicago, Ill.* The perfused isolated spinal cord lends itself admirably to combined functional and metabolic studies. A technique has been developed for removing the rat thoracic cord supported on vertebral bodies, fixing in plaster, and perfusing (after Galli-Manini) with Tyrode plus glucose (100 mg %) plus purified egg albumin and, sometimes, washed beef erythrocytes, at regulated temperature, pH, CO₂, CCO₂, arterial, and pulse pressure. Flow averaged 1 cc/gm/min. Reflex activity, tested by stimulating a dorsal root and recording ventral root potentials, continued undiminished in experiments lasting over 3 hours. One minute asphyxia or 2 to 4 minutes perfusion without glucose abolished reflex response. Recovery was complete within 2 minutes on restoring oxygen or glucose, even after more than 30 minutes deprivation. Average glucose utilization, 7.5 mg/gram wet weight per hour (range 7.1 to 8.0), corresponds to a QO₂ of 5000. Adrenaline increases the reflex response of a failing preparation. The areflexia of aglycemia can be used to test the ability of other substrates to support function. After 15 minutes inactivity without glucose (and later return with glucose) the following were ineffective, although several are easily oxidized: alcohol, acetate, lactate, β -hydroxybutyrate, fumarate, malate, succinate, adrenaline, dl alanine, dl lysine,

l tyrosine, dl aspartic, dl cysteine and l cystine. The following, in contrast, restored full function: pyruvate, oxaloacetate (partial restoration), isocitrate, α -ketoglutarate, glutamate and glutamine. Ammonia and glucose appeared in the perfusate with glutamate, glucose with α -ketoglutarate. Seemingly, successful metabolism of a substrate does not guarantee support of function.

Effect of abdominal ice packs on recovery from fatigue. W. W. TUTTLE, W. P. HAPP (by invitation) and M. WILSON (by invitation) *Dept. of Physiology, State Univ. of Iowa, Iowa City, Ia.* It has been reported that cold hip baths were employed in Germany during the last World War, in both industry and the air force, to ward off the onset of fatigue and to hasten recovery from it. It is the purpose of this investigation to gain further information relative to the beneficial effects of the local application of cold on recovery from fatigue. The problem was approached by comparing the maximum amount of work a subject would do on a bicycle ergometer in one minute of maximum effort before and after a 10-minute rest, both without and with an ice pack applied to the abdomen during the rest period. Eleven graduate men ranging in age from 25 to 35 years, and in weight from 130 to 200 pounds, served as subjects. A study of the data showed, that in every case, the drop-off in work following a rest period with an abdominal ice pack was significantly less than when the ice pack was omitted. The mean drop-off in work for the subjects when the abdominal ice pack was omitted from the rest period was 225 kg.M. and when ice was applied the mean drop-off was 69 kg.M. This difference is significant at the 1% level of confidence. It was also observed that for the most part, the application of abdominal ice packs between bouts of strenuous exercise alleviated the symptoms of exhaustion such as dizziness, nausea and muscular weakness.

Residual electrocardiograms. WILLIAM G. TURMAN (by invitation) and JANE SANDS ROBB *Dept. of Pharmacology, Syracuse Univ. College of Medicine, Syracuse, N. Y.* In order to test the adequacy of our recording instruments for another study, various standard extremity, unipolar extremity and direct leads were recorded from turtles. Cardiac tissue was progressively cut away eliminating first the ventricle, then one and finally both atria. With the entire heart excised potentials from two pacemakers were still recorded. Inspection showed movement of the intrapericardial portions of right and left veins. These had to be resected far into the thorax before the galvanometer became quiescent. When but a few millimeters of one vein remained and pulsation of one spot, approximately 1 mm. sq., could be seen with a hand lens, potentials were still recorded from direct electrodes either paired to each other or with each paired to

the central terminal which in turn was connected to 3 extremities. From this small area of pulsating vein, whose anatomical arrangement is relatively simple, Q-, R-, S-, and T-waves were registered. During this procedure there was a surprising maintenance of voltage suggesting considerable neutralization of current in the intact turtle. This study lends support to the view that the heart too has functional 'unit' areas which become activated, contract and produce each of the characteristic electrocardiographic waves. Although injury to some given area of the intact heart may alter the total electrocardiogram by altering summation, it seems unjustified to state that activation of some specified area is the cause of a given wave.

Effect of dinitrophenol on respiration of excised brains of rats at various stages of development. DAVID B. TYLER *Dept. of Embryology, Carnegie Inst. of Washington, Baltimore, Md.* To test the hypothesis that the mechanisms involved in oxygen consumption may differ in brains of different ages, the effect of dinitrophenol, $10^{-5}M$, was determined on the minced brain of rats, ranging in age from new born to adult, by means of Warburg respirometers. The oxygen uptake of the new born pallium (less than 24 hours old) is increased by an average of 28%. During the next 7 days there are indications that the sensitivity to the stimulating effect of this drug is diminished. The pallium of the 3-day-old rat shows only a 15% increase with the same concentration of dinitrophenol. Beginning about the 8th day there occurs a gradual increase in the response to dinitrophenol until the adult level is reached. Under the conditions of these experiments dinitrophenol ($10^{-5}M$) increases the oxygen uptake of the adult pallium by an average of 40%. No significant regional differences in response to dinitrophenol have been found. However, dinitrophenol enhances the depression of respiration produced by malonate or iodoacetate, depending upon the sensitivity of the region to the inhibitor. Thus the addition of dinitrophenol and iodoacetate to a suspension of minced adult medulla results in a lower oxygen uptake than when iodoacetate only is added, whereas a combination of dinitrophenol and malonate results in approximately the same oxygen consumption as occurs if malonate alone is added. In the case of the adult pallium a combination of dinitrophenol and malonate results in a significantly lower oxygen uptake than when malonate alone is used whereas the oxygen uptake of that region in media containing a combination of dinitrophenol and iodoacetate is approximately the same as when iodoacetate alone is used. The results with dinitrophenol support the hypothesis that the growth of the brain of the rat is accompanied by qualitative or quantitative differences in the systems responsible for its oxygen uptake.

Fibrinolysin activation by specific antigen, peptone and polysaccharides GEORGES UNGAR (introduced by A A SCHILLER) *Rheumatic Fever Research Inst, Northwestern Univ, Chicago, Ill* It is known that active proteolytic enzyme can appear when its inactive precursor present in serum is treated with chloroform or streptokinase. Activation has now been found to occur on addition of the antigen to serum from guinea-pigs previously sensitized to egg albumin. Activation was also observed in normal guinea-pig serum treated with peptone, agar, hyaluronic acid, chondroitinsulfuric acid, glycogen, pneumococcal polysaccharides and heparin. Higher concentrations of heparin however inhibit activation. The activating agent was added to serum which was then diluted with distilled water and adjusted to pH 5.4. The resulting precipitate, containing the enzyme, was centrifuged, redissolved and tested for proteolytic activity by a very sensitive fibrinogenolytic method and also by viscosimetry. Activation under the conditions mentioned above differs from the chloroform or streptokinase induced activation by the fact that it does not occur when the activating agent is added to the euglobulin precipitate or to serum previously heated to 56°. The findings reported here may have some bearing on the mechanism of anaphylactic and anaphylactoid reactions and on the functions of some high molecular carbohydrates.

Effects of explosive decompression on blood temperature in the right and left heart EDWIN G VAIL (by invitation) and FRED A HITCHCOCK *Dept of Physiology, Ohio State Univ, Columbus, Ohio* The development of the thermistor makes available an instrument for the precise measurement of small and rapidly occurring temperature changes. Experiments have already been reported in which thermistors were used to record temperature changes in the lungs. In the experiments reported in this communication, thermistors were inserted through the right jugular vein into the region of the right heart and through the right carotid artery into the region of the left heart. The exact location was determined by autopsy. Temperatures were recorded by means of a two channel ink-writing oscillograph. The temperature in the right heart was found to be slightly higher than that in the left heart. There were slight fluctuations in the temperature of the right heart which could be correlated with respiratory movements and may possibly be due to the proximity of the superior vena cava to the respiratory passages. No temperature fluctuations were observed in the left heart. Following explosive decompression to 30 ± 5 mm Hg there was an immediate drop in the temperature of the right heart and two or three seconds later, a drop in the temperature of the left heart. This decrease in temperature was greater in the left than in the right heart. The maximum drop in temperature occurred in about 20 seconds.

Studies on the effect of anoxic anoxia on sheep blood sugar and hemoglobin EDWARD J VAN LIERE, J CLIFFORD STICKNEY and DAVID W NORTHUP *Dept of Physiology, West Virginia Univ School of Medicine, Morgantown, W Va* Sheep were chosen for these experiments because of their known low fasting blood sugar. Two castrate male Corriedale lambs (no 32 23.6 kg and no 53 27.4 kg) were studied in regard to blood sugar and hemoglobin in jugular vein samples drawn after a 24-hour fast under control conditions and before and after 30-minute exposures at weekly intervals in a decompression chamber to simulated altitudes. Blood sugar was determined colorimetrically on Somogyi-Shaffer-Hartmann filtrates and hemoglobin by the Sahl method. The average control blood sugar in the 2 sheep was 52 and 53 mg/100 ml. Sheep 32 responded to a 30-minute stay in the decompression chamber at ground level with an average rise of 10 mg/100 ml in blood sugar in 4 tests. Sheep 53 in 3 tests showed no further rises after the first. The first exposure to 22,000 ft produced rises in blood sugar of 40 and 24 mg/100 ml in sheep 32 and 53 respectively. Subsequent exposures to altitudes from 18,000-28,000 ft produced no significant blood sugar rises in sheep 32. Similar exposures in sheep 53 produced rises of 6-18 mg/100 ml. Blood hemoglobin was also followed before and after exposure to anoxia. Sheep 32 consistently responded with an increase in hemoglobin concentration. Sheep 53 responded at first with small elevations, but later with reductions in hemoglobin concentration.

Pharmacology of N, 1 dimethyl hexylamine (Oenethyl) J H WILLS, *Dept of Pharmacology, Univ of Tennessee, Memphis, Tenn* In the dog anesthetized with pentobarbital sodium, N, 1 dimethyl hexylamine (Oenethyl) has both depressor and pressor actions, the latter predominating. The pressor action appears to have a dose-effect curve of the general form $Y = A + BX$, it is blocked by ergonovine but not by ergotamine or ergotoxin. Oenethyl increases the tonus of both jejunum and uterus *in situ*. The drug produces premature ventricular contractions but fibrillation has not been seen. The rate and depth of respiration may be increased by Oenethyl.

Permeability of rabbit leucocytes to sodium and potassium D L WILSON (by invitation) and J F MANERY *Dept of Biochemistry, Univ of Toronto, Toronto, Canada* Rabbit leucocytes were suspended in buffered solutions, the osmotic pressure of which was largely supplied either by sucrose or ammonium chloride. In the sucrose solution the chloride and potassium concentrations of the cells decreased 80% and 50% respectively. In the ammonium chloride solution the intracellular potassium decreased 90%, the intracellular sodium about 80%. The permeability to sodium was further studied by examining the penetration of Na^{22} .

During the first 75 minutes after exposure to the isotope the specific activity (i.e. counts/min/m Eq) of the sodium inside the cell was 90% of that outside. In addition, data were obtained which show that the external concentration of glucose influences the intracellular sodium and potassium concentrations of leucocytes.

Inhibition of growth of mice on a low protein, choline deficient diet by coramine J. WALTER WILSON and ELIZABETH H. LEDIC (introduced by PAUL F. FENTON) *Brown University, Providence, R. I.* Weanling mice were fed a low protein (4% casein) choline deficient diet, and the same diet with coramine. Without coramine, they grew slowly to nearly adult size and were still gaining slightly at 200 days. They had very fatty livers. With coramine, growth was greatly inhibited. With 1% coramine a gradual loss of weight occurred for 15 days. The mice were then fed 3 mg of choline by stomach tube whenever they showed signs of decline. They were maintained 64 days with no gain of weight. There was no fat in the liver. With 0.5% coramine growth was completely inhibited, but the mice were maintained 84 days without supplementary choline. With 0.25% coramine a slight but varied growth occurred but it did not approach that on the basal diet. The livers contained considerable fat. The basal diet contains a minimum of labile methyl groups. Detoxication of coramine occurs by transmethylation. 0.25% coramine added to the diet leaves just enough labile methyl groups for very slight growth, 0.5%, just enough for maintenance without growth, 1% requires so many that not enough are left for maintenance and the animal declines. This can be corrected by choline. This effect of choline cannot be attributed to its lipotropic action, for on 1% coramine the liver is not fatty. The choline must supply methyl groups. On a low protein diet then, choline may supply methyl groups for the detoxication of excess coramine, thus permitting maintenance during prolonged inhibition of growth.

Effect of antihistaminic drugs upon trained rats CHARLES A. WINTER and LARS PIATIER (by invitation) *Merck Inst. for Therapeutic Research, Rahway, N. J.* Antihistaminic drugs affect central nervous system activity as is evident from the side reactions observed in man, but this effect has not

to climb as do untreated rats, but they appear to be weak and easily become fatigued. Sufficient doses of antihistaminic drugs, on the other hand, make the animal become confused, and unable to decide whether to climb or not. It is therefore tentatively assumed that the results are a demonstration of central action of antihistaminic drugs. The central mechanism involved may not be the same one that was measured in experiments on barbiturate potentiation, because the compounds do not fall in the same order of graded activity in the two experiments. Two compounds having especially strong activity in the rope climbing test are Phenergan, N-(β -dimethylamino- α -methyl-ethyl)-phenothiazine, and Diparcol, N-(β -diethylamino-ethyl)-phenothiazine. Both of these compounds have been reported to be useful in the treatment of Parkinsonism.

Effect of potassium deficiency upon gastrointestinal motility HELEN A. WINTER (by invitation), HEBBERLE HOFF and LESLIE DSO (by invitation) *Dept. of Physiology, McGill Univ., Montreal, Canada.* The motility of the gastrointestinal tract has been investigated in rats during potassium deficiency, and the therapeutic effects of potassium have been shown. Potassium deficiency was induced by reducing the intake of potassium or by injecting desoxycorticosterone. Synthetic diets were given ad libitum or by stomach tube. Observations on motility were made by X-ray and by inspection of the gut and were correlated with studies of potassium metabolism. In potassium deficient rats the tone and rhythmicity of the whole gut were reduced, particularly in the small bowel and stomach. Gas and fluid accumulated in the ileocecal tract. Evacuation of barium was very slow. While normal animals evacuated barium from the stomach in about three hours and excreted more than one half in five hours, deficient rats usually retained some barium in the stomach for a day and often excreted little barium in this time. In some the cecum reached gigantic proportions. In force fed animals tremendous distention developed suddenly which proved fatal in all untreated rats. Therapy with potassium relieved the symptoms in surprisingly short time. In animals injected with potassium rhythmic contractions were initiated in the small bowel within four

Jefferson Medical College, Philadelphia, Penna. All subjects were patients with proved duodenal ulcer. Treatment periods ranged from 11 to 15 months and data are adjusted for a 12-month period. *Series A* 34 patients received orally 12 to 15 gm of dried defatted duodenum substance per day, plus ulcer diet. Average number of 'ulcer attacks' per year were 3.1 before treatment and 0.4 after treatment. X-ray evidence of ulcer healing was not obtained in 4 cases. *Series B* 15 patients received 12 gm enteric coated lactose tablets per day plus ulcer diet. Average number of 'ulcer attacks' per year were reduced from 3.2 to 0.1. All patients showed X-ray evidence of ulcer healing. *Series C* 18 patients received ulcer diet alone. Average number of 'ulcer attacks' per year were reduced from 3.3 to 0.5. One patient gave no X-ray evidence of ulcer healing. It is concluded that, when given daily for a period of 11 to 15 months in doses approaching the maximum tolerated by the patient, dried defatted whole duodenum did not prove to be of benefit to the patient with peptic ulcer.

New evidence on the nature of cutaneous hyperalgesia. HAROLD G. WOLFF, H. GOODELL (by invitation) and JAMES D. HARDY. *New York Hospital and the Depts. of Medicine, Psychiatry and Physiology, Cornell Univ. Medical College, New York City.* Two important types of Hyperalgesia in the skin were identified as regards their special characteristics: 1) That occurring at the site of skin injury characterized by lowered pain threshold, increased sensitivity to noxious and ordinarily non-noxious stimuli and termed for convenience primary hyperalgesia. 2) Secondary hyperalgesia, occurring in areas of undamaged skin characterized by unchanged pain threshold but increased sensitivity to noxious stimulation. Development of secondary hyperalgesia has been observed following prolonged stimulation at or just below the pain threshold. Such hyperalgesia ends immediately on termination of stimulation. Temporary obliteration of secondary hyperalgesia can be accomplished by pin pricks within the zone of secondary hyperalgesia. Spatial summation of noxious impulses has been observed to be a characteristic of painful stimulation in the zone of secondary hyperalgesia. All of the above evidence further supports the view that secondary hyperalgesia is the result of a central excitatory state maintained by a flow of noxious impulses from the periphery.

Effect of altered metabolism on extreme hypothermia in dogs and albino rats. RICHARD C. WOLFF (by invitation) and K. E. PENROD. *Dept. of Physiology, Boston Univ. School of Medicine, Boston, Mass.* Twenty-nine rats fed 0.03% propylthiouracil in the diet for 24 days, 30 fed 0.12% thyroid extract for 9 days, and 28 controls were cooled by immersion to the shoulders in water of 7°C.

Twenty rats receiving 0.03% propylthiouracil for 30 days, 16 receiving 0.50% thyroid extract for 15 days and 20 controls were cooled in a similar manner. The rats which were fed the propylthiouracil diet showed a metabolic depression of 15% while the group fed a 0.12% thyroid diet showed a stimulation of 14% and those receiving the 0.50% diet showed a stimulation of 41%. The first group of 87 rats was cooled to a rectal temperature 15.8-16.0°C. Sixty-nine per cent of the hypothyroid, 75% of the control and 63% of the hyperthyroid rats survived. The second group (56 rats) was cooled to a rectal temperature of 14.8-15.0°C. Forty-nine per cent of the hypothyroid, 50% of the control and 38% of the hyperthyroid rats survived. The rate of cooling to a rectal temperature of 20°C in a bath of 4°C, the time of rewarming in water and air to 31°C and the oxygen consumption were measured on 6 dogs, twice each. Two of the dogs succumbed in 'rewarming death'. The 4 surviving dogs were fed 4 mg/kg thyroid extract for 13 days and again cooled. Only one dog showed an increased metabolism and all showed an increased rate of cooling. In 2 cases the rewarming time was lessened, in 2 increased. It is concluded that during immersion in very cold water the metabolic defenses of the animal are not capable of significant protection.

Rapid methods for enzymatic estimation of nucleoprotein intermediate metabolites by differential colorimetry. W. Q. WOLFSON (by invitation), C. COHEN, R. LEVINE and K. KADOTA (by invitation). *Depts. of Biochemistry and of Metabolic and Endocrine Research, Medical Research Inst., Michael Reese Hospital, Chicago, Ill.* Since the purine intermediates in nucleoprotein breakdown eventually give rise to urate when exposed to suitable enzymes, the methods here proposed consist of measuring the quantitative appearance of urate (colorimetrically) after incubation of the sample with known enzyme solutions. Enzyme purification need only be carried far enough to yield a liquid preparation of satisfactory specificity which gives no blank in the determination and may be stored frozen. The procedures now in use include: 1) *True urate*, estimated from urate disappearance after treatment with beef kidney uricase. 2) *Oxypurine (xanthine plus hypoxanthine)*, estimated as urate appearing after treatment with xanthine oxidase from raw milk. 3) *Purine nucleoside plus oxypurine*, estimated from urate appearing after treatment with xanthine oxidase and nucleosidase from human liver. The latter has adenosine desaminase activity, but has little guanase and no adenase activity. 4) *Purine nucleoside*, calculated by subtracting #2 from #3. 5) *Purine nucleoside, aminopurine and oxypurine*, estimated from urate appearing after treatment with xanthine oxidase, nucleosidase and crude adenase.

gunnase from *Esch coli* 6) *Aminopurine*, estimated by subtracting #3 from #5. Apart from their simplicity, these procedures have the advantage of being relatively free from interference by side-reactions, such as the conversion of methyl-xanthenes to methylurates during xanthine oxidase treatment. An example of the application of one of these methods to physiological problems is given elsewhere in these proceedings.

Metabolism of oxypurines in man preliminary observations WILLIAM Q. WOLFSON (by invitation), CLARENCE COHN and KINU KADOTA (by invitation) *Dept of Biochemistry, Medical Research Inst., Michael Reese Hospital, Chicago, Ill.*

In man, the physiological course of intermediate purine metabolism prior to urate is largely unknown. The liver may be the chief site of urate production since it is believed to be the sole locus of xanthine oxidase, and because extraordinarily low blood urate levels have been reported in acute yellow atrophy. Oxypurines might be produced in the periphery and transported to the liver for conversion to urate, about $\frac{1}{10}$ being excreted by the kidney. If so, a significant increase in serum oxypurine should occur in hepatic, but not in renal, insufficiency. However, a large portion of the oxypurine might be formed as well as metabolized in the liver, and, in this event, oxypurine precursors rather than oxypurine should be retained in hepatic insufficiency. It has also been suggested that gouty hyperuricemia might be associated with a failure of inhibition normally exerted on hepatic xanthine oxidase. Serum and urine oxypurines have been determined by differential enzymatic colorimetry. In 14 normal adults, serum oxypurine averaged 0.30 mg % (S.D. \pm 0.14 mg %). Serum oxypurines were not elevated in pooled sera from patients with liver damage or renal insufficiency, but these data are not sufficiently consistent to permit definite conclusions as yet. The average serum oxypurine in repeated samples from five gout patients averaged 0.11 mg %. This result is consistent with the suggestion that there may be a relative hyperactivity of hepatic xanthine oxidase in gout.

Oximetric measurement of circulation time and arterial saturation time during oxygen breathing in man EARL H. WOOD, BOWEN E. TAYLOR (by invitation) and JULIAN KNUTSON (by invitation) *Section on Physiology, Mayo Foundation, Univ of Minnesota, Rochester, Minn.* Arterial saturation was recorded continuously and simultaneously both at the ear and wrist (abstract J. Knutson et al.) in 6 subjects as the gas mixture breathed was changed from air to 40% O₂, from 40 to 99.6% O₂, and from air to 99.6% O₂. After changing from air to 40% O₂ and air to 100% O₂, the initial increase in saturation (circulation time, Matthes) occurred at 6.2 (3 to 9) and 9.6 (6 to 12) seconds at the ear

and wrist, and the maximal plateau value was attained at 47 (19 to 74) and 46 (19 to 71) seconds, respectively. Time required to increase from 97.9% to the plateau value minus 0.5% (Fowler and Comroe), averaged 25 (11 to 58) seconds at both the ear and wrist, as compared to 19 (14 to 28) seconds (ear) and 25 (18 to 30) seconds (wrist) required to increase from 71 to 97 per cent after termination of breath-holding with helium (abstract J. Knutson et al.). Changing from 40 to 100% O₂ produced an increase in arterial saturation both at the ear and wrist, averaging 0.40 (0.2 to 0.5) and 0.35 (0.1 to 0.7) %, respectively. The approximate arterial O₂ tension calculated from the physically dissolved oxygen (O₂ content—O₂ capacity) averaged 213 and 595 mm Hg when 40 and 100% O₂, respectively, was breathed. The similarity in time and the magnitude of changes in arterial saturation recorded photoelectrically at the ear and directly on the arterial blood at the wrist indicate that an ear oximeter can be used successfully for determination of circulation and arterial saturation times in man.

Passive sensitization of normal dogs by thoracic duct lymph from dogs sensitized to horse serum PARKE H. WOODARD (introduced by K. E. JOCHIM) *Dept of Physiology, Univ of Kansas, Lawrence, Kan.* It is known that normal dogs may be passively sensitized to horse serum by transfusing into them blood from dogs previously sensitized to horse serum and that they will exhibit some of the symptoms of anaphylactic shock upon intravenous injection of horse serum. The symptoms most generally reported have been a fall in arterial blood pressure and changes in blood coagulation time. I have been able to confirm previous work from this laboratory that such passive sensitization is immediate and does not require lapse of time as has been reported by some workers. Not all sensitive animals are capable of passively sensitizing normal animals. In those which are capable it was thought worth while determining whether or not antibodies were distributed in other body fluids than blood. Accordingly dogs were sensitized to horse serum. Each animal was anesthetized with nembutal and the thoracic ducts cannulated and sufficient lymph collected for injection into a second anesthetized dog. In most cases blood was also drawn from the sensitized animal and transfused into a third anesthetized dog. Blood pressure records and blood clotting times were recorded on all animals before and after the administration of shock doses of horse serum. Eight control experiments were run in which the lymph and blood from normal dogs was similarly tested. These showed no evidence of shock. Of 11 experimental animals, 2 were not sensitive, 4 were sensitive but did not passively transfer immunity either through blood or lymph, 1 showed passive transfer through

blood but not lymph, 4 showed evidence of passive transfer by both blood and lymph

Antagonism of adrenocorticotrophic hormone (ACTH) to desoxycortico-costerone acetate (DCA) on electroshock threshold and electrolytes DIXON M. WOODBURY (by invitation), CHI-PING CHENG (by invitation) and GEORGE SAYERS *Depts of Physiology and Pharmacology, Univ of Utah College of Medicine, Salt Lake City, Utah* By the 12th day after implantation of DCA (six 15 mg pellets into each of 14 rats) the electroshock threshold had risen to +17%, 14 controls showed no significant change (+2%) Beginning on the 12th day, 7 of the DCA-implanted rats and 7 of the controls were injected twice daily for ten days with 2 mg of ACTH On the 22nd day the electroshock thresholds of the four groups were as follows I) control, +3%, II) ACTH, +6%, III) DCA, +22%, IV) DCA +ACTH, +5% When ACTH was withdrawn from group IV the threshold rose to +17% by the 32nd day Readministration of ACTH resulted in a threshold reduction to +10% after 9 days, III had an average threshold of +24% at this time (41st day) DCA elevated plasma sodium and reduced plasma potassium and chloride ACTH partially corrected the deranged electrolyte pattern of the DCA-treated rats Whole extract of adrenal cortex restored to normal the elevated threshold of DCA-implanted rats Since ACTH did not influence the elevated electroshock threshold of adrenalectomized rats implanted with DCA, the trophic acts via the adrenals The results are interpreted to mean that DCA in intact animals, produces a relative deficiency of cortical steroids with an O on C-11 by inhibiting the release of ACTH from the pituitary

Early components of contralaterally evoked cortical potentials in the intact unanesthetized rat LOWELL A. WOODBURY (introduced by J. E. P. TOMAN) *Dept of Physiology, Univ of Utah College of Medicine, Salt Lake City, Utah* As a preliminary to a study of the action of central excitant and depressant drugs, control observations were made on the initial components of the electrocorticogram evoked by stimulation of the contralateral hemisphere in ten unanesthetized intact rats Epidural insulated screw electrodes were implanted under anesthesia one or two days prior to each experiment Brief rectangular pulses or condenser discharges were delivered to the visual cortex of one hemisphere, while responses were taken from the symmetrical contralateral area The characteristic initial response to submaximal stimuli consisted of two initially surface-positive spikes and a third surface-negative spike with latencies of 1.8-2.0, 3.4-3.6, and 4.0-4.2 msec respectively A voltage-response study of the large third spike showed a relatively homogeneous response population Strength-duration curves for

this response gave a limiting log-log slope of -0.7 and a chronaxie of 0.18 msec The recovery curve following maximal responses exhibited relative refractoriness to 2.5 to 3.0 msec followed by a period of greatly enhanced excitability with a peak at 4.0 to 6.0 msec Since this phase was absent when conditioning responses were reduced below the amplitude of test spikes, it is attributed to a true supernormal period of previously responding elements rather than to indirect facilitation This phase was followed by subnormal excitability with a minimum in the vicinity of 10-20 msec and further minor oscillations at equal log-time intervals to at least 400 msec

The pattern of localization in the motor cortex of the marmoset (*Hapale jacchus*) C. N. WOOLSEY, P. H. SETTLAGE (by invitation), H. M. SUCKLE (by invitation) and W. G. BINGHAM (by invitation) *Depts of Physiology, Anatomy and Surgery, Univ of Wisconsin, Medical School, Madison, Wis* We have examined in detail the motor area of this primitive new world monkey in order to compare the pattern of organization with the relatively simple plan found in the rat (see abstract by Settlege et al) Certain comparisons are possible, but the main features of the primate arrangement have already been established The relation of the motor pattern to that of the post-central tactile area as defined by the evoked potential method (unpublished data, C. N. W.) will be considered

Actions of dihydro-B-erythroidin and dtubocurarine on neuromuscular and synaptic transmission in frog and crayfish ERNEST B. WRIGHT (introduced by W. O. FENN) *Dept of Physiology and Vital Economics, Univ of Rochester School of Medicine and Dentistry, Rochester, N. Y.* 2 mg/kg dihydro-B-erythroidin (eryth) and 4 mg/kg dtubocurarine (dtubo) paralyze the frog in 20 and 30 minutes respectively, neuromuscular transmission being totally blocked Neuromuscular transmission in the isolated sciatic-sartorius is blocked by immersion in 5×10^{-7} eryth and 5×10^{-6} dtubo with reduction of the endplate potential Action potentials in the crural nerve and contractions of the cruralis muscle with blood supply tied off, elicited by stimulation of the foot skin, knee skin or sciatic nerve show that a) sensory endings and nerve conduction are unaffected by both drugs, b) transmission of flexion reflex is unaffected or slightly enhanced by dtubo, greatly depressed or blocked by eryth The crayfish is unaffected by 50 mg/kg dtubo, but paralyzed in 2 minutes by 0.05 mg/kg and in 10 seconds by 1 mg/kg eryth Sensory endings, nerve conduction and neuromuscular transmission are unimpaired at these concentrations Spontaneous impulses originating in the central system and led off from peripheral nerve are extinguished with remarkable sudden-

ness by eryth, but are unaffected by dtubo. Electrical recordings from the ventral nerve cord and from roots of the abdominal ganglia show that eryth has no effect on giant fiber conduction, blocks transmission from giant fiber to root, depresses the spontaneous activity of the cord somewhat, and depresses greatly or blocks the spontaneous activity led off from the root originating presumably in the attached ganglion. Eryth, unlike dtubo, blocks central synaptic transmission in frog and crayfish, and like dtubo blocks neuromuscular transmission in frog.

Anti-stiffness factor in relation to hearing in guinea pigs. ROSALIND WULZEN and ALICE B. PLYMPTON (by invitation) *Dept. of Zoology, Oregon State College, Corvallis, Ore.* 117 guinea pigs were divided into two groups, one on stock diet, the other on diet deficient in anti-stiffness factor. The stock diet consisted of rolled barley, green feed and straw. The deficient diet was composed of skim milk powder and water, plus an adequate supply of minerals and all known vitamins except the anti-stiffness factor. For the test, animals were exposed to signals from an audio signal generator combined with loud speaker and key. They responded with flicking of the ears to a wide range of auditory stimuli. Only slight deviations were found in repeated readings for any one animal. Limits of normal hearing, judged by the ear flick and expressed as frequency in cycles per second, were established as follows: low range, 200-450, high range, 10000-15000. Of 45 animals on stock diet, 41 proved to have normal hearing, 4 had restricted hearing, none were completely deaf, that is, without ear flick response. Of 72 animals exposed to deficient diet for varying lengths of time, 42 showed normal hearing, 15 had restricted hearing, 15 were completely deaf, that is, without ear flick response.

Fasting serum vitamin A and carotene levels, and vitamin A absorption in males over 40. MARVIN J. YIENGST (by invitation) and NATHAN W. SHOCK. *Section on Cardiovascular Diseases and Gerontology, National Heart Institute, National Insts. of Health, and Baltimore City Hospitals, Baltimore, Md.* The purpose of this investigation was to study age changes in absorption of vitamin A and fasting levels of vitamin A and carotene in a population living under homogeneous conditions. Fasting levels were determined on 121 males ranging in age from 40 to 90 years who were unselected except to exclude any subjects with clinical signs or history of liver disease. All subjects were residents of the Baltimore City Hospitals and Infirmary (Old People's Home) and were receiving an adequate diet. The method of Bessy, Lowry, Brock, and Lopez (*J. Biol. Chem.*, 166, 177, 1946) was used in the determinations. The serum vitamin-A levels ranged from 10 to 88 and per 100

ml with a mean of 49.9. Arranged by decades, the 5 groups from 40 to 90 years of age showed no age differences. The carotene levels ranged from 28 to 231 and per 100 ml with a mean of 113.1 and likewise showed no significant age difference. A low positive correlation exists between the fasting vitamin A and carotene levels ($r = 0.17$, $N = 121$) in the serum. Fifty-four males included in the above group were fed 100,000 U of vitamin A in oil. Blood samples were drawn at 0, 2, 4, 6, 8, 10, 16, and 24 hours after oral administration. Mean values in and per cent for the group at these times were 53.4, 125.3, 150.2, 172.1, 118.9, 96.7, 73.0, and 63.3. There were no age differences in response to oral administration of vitamin A. Serum carotene values remained unchanged.

Effects of DOCA and adrenal cortical extracts on survival of adrenalectomized rats after burning. S. S. YU (by invitation) and E. A. SLIERS. *Dept. of Physiology, Univ. of Toronto, Toronto, Canada.* Rats of both sexes weighing about 150 gm were bilaterally adrenalectomized and maintained on saline for 4-10 days. They were then divided into 3 groups, the first of which constituted a control and continued to receive saline. Desoxycorticosterone acetate and adrenal cortical extract were administered to the second and third groups, which were allowed water ad libitum. A standard burn was produced under ether anesthesia by immersing the backs of all animals in water at 85°C for 30 seconds. This proved lethal in 2-42 hours to the control group (10 animals). The 28 rats of the second group received DOCA by subcutaneous injection in daily doses of 0.25, 0.50 and 1.0 mg for 4 to 7 days prior to burning. At the higher dosage levels DOCA afforded a definite protection, 4 of the 5 animals which received 0.5 mg/day for 7 days survived. All the 9 animals receiving 1.0 mg/day for 7 days survived, while in another group of 9 rats which were given the same dosage for 4 days, 2 died. Adrenal cortical extracts from different sources (Connaught and Upjohn Laboratories) were administered to group 3 in doses varying from 15 to 150 dog U/day (divided doses when the dosage was high) for 4-8 days. Among the 24 rats thus treated only 2 animals which received 60 and 150 U/day respectively survived the burning. The effects of these substances on intact animals subjected to a similar stress will also be reported.

A respirator and perfusion pump with new features and an improved constant injection apparatus (motion picture). W. B. YOUNG. *Dept. of Physiology, Univ. of Oregon Medical School, Portland, Ore.* A piston pump, having new features, and an improved constant injection apparatus have been designed and constructed for this laboratory by the Martin-Hubbard Corp., Boston. The pump will deliver any stroke volume between zero and 1000 cc. A rate continuously

variable from zero to 180/min is obtained by the use of a Graham transmission unit. Either rate or stroke volume can be changed through the entire range without stopping the motor. There are 4 input ports and one output port. All parts are made of metal, the valves consisting of an axle with sectors cut out to permit passage of the gas at the proper phase of the cycle. The piston empties the cylinder at each downstroke regardless of the stroke volume. A pump having the same basic features with a smaller maximum stroke (500 cc) which will deliver against pressures in the range of arterial blood pressure is designed also. Use of the instrument to pump gases directly and indirectly and to pump liquids indirectly will be shown. The constant injection apparatus consists of a Graham transmission unit geared to turn a threaded shaft against the plunger of a syringe of any size up to 50 cc. Any injection rate between zero and 10 cc/min can be obtained without stopping the motor. Uses of the instrument to maintain steady submaximal effects by continuous intravenous injection will be shown.

Bone absorption and relaxation of guinea pig pelvis by prolonged estrogenic injections. WILLIAM C. YOUNG (by invitation) and FREDERICK E. EMERY, *Dept. of Physiology and Pharmacology, Univ. of Arkansas School of Medicine, Little Rock, Ark.* The effects of various estrogens on the pelvis of the guinea pig have been studied in about 60 young guinea pigs of both sexes. The males were injected with 1.0 mg of diethyl stilbestrol in olive oil for a duration of several months. Periodic X-rays were taken throughout the injection period. By palpation and X-ray it was demonstrated that there was a separation of the pelvis varying from little or no separation to almost complete relaxation in some cases. The testes seemed to be dominated by the estrogens, as shown by the fact that the separation at the pubic symphysis was almost as pronounced in males as in castrated males. Female guinea pigs treated in a similar manner with 0.1 mg of stilbestrol twice weekly have shown bone absorption and relaxation. So far complete disappearance of the bony pelvis, like that of the pocket gopher, has not been obtained.

Response of the young cockerel to methyl folic acid and testosterone propionate. M. X. ZARROW and I. B. KORETSKY (introduced by F. L. HISAW), *Biological Labys, Harvard Univ., Cambridge, Mass.* Studies were made on the relationship of folic acid to the response of the testis and comb of the chick to testosterone propionate. A folic-acid-deficient state was produced by the administration of a crude methyl folic acid preparation (courtesy of Dr. E. L. R. Stokstad, Lederle Laboratories) in the diet. Day-old cockerels of the Leghorn strain were divided into 4 groups of 10 each and treated in the following manner: 1) normal con-

trols, 2) 100 γ of testosterone propionate daily, 3) 2% methyl folic acid in the diet, and 4) 2% methyl folic acid in the diet plus 100 γ of testosterone propionate daily. The androgen was dissolved in sesame oil and injected subcutaneously in a daily volume of 0.05 ml. In the first experiment the chicks were treated for 7 days and killed on the 8th day at which time organs were removed for weight determination and histological examination. The testis weights for the 4 groups were 20, 15, 20 and 10 mg respectively or 27, 20, 28 and 16 when expressed as a function of the body weight. The absolute comb weights were 21, 76, 16 and 54 mg and the relative weights were 52, 98, 39 and 83. A second experiment in which 4% methyl folic acid was used in the diet gave essentially the same results for testis response. The comb weights were 34, 83, 24 and 106 mg or 40, 90, 37 and 163 respectively when expressed as a function of body weight. These results would seem to indicate that testosterone propionate was able to produce comb growth in the presence of the antagonist.

Effect of adrenoxyl on blood loss from surgical wounds. J. J. ZAVERNIK and R. F. HAGERTY (introduced by K. S. GRIMSON), *Dept. of Surgery, Duke Univ., Durham, N. C.* Adrenoxyl, a mon-semicarbazone of adrenochrome, reportedly decreases bleeding time of rabbits and man. In our studies in dogs it was determined that intramuscular injection of 10 gamma of Adrenoxyl does produce a marked decrease, effect being maximal by 30 to 60 minutes. A study of ability of the drug to decrease blood loss from surgical wounds was also undertaken. Consecutive apparently similar incisions were made in the liver of dogs estimating bleeding by weight of blood collected. One hour after administration of 10 gamma of Adrenoxyl amount of bleeding decreased markedly. Wounds were also produced by resection of similar portions of a rabbit's two ears. Amount of blood loss was found decreased moderately one hour after administration of 10 gamma of Adrenoxyl. Three similar wounds were produced on opposite ears of the same rabbit 5 days apart. The 3 different wounds produced on one ear before the drug bled respectively an average of 31 gm, 72 gm and 80 gm of hemoglobin, increasing amounts representing the larger or more proximal incisions. Five days later 3 similar wounds were made after Adrenoxyl using the opposite ear. Decrease in bleeding after administration of Adrenoxyl was 44.7%, 3.7%, and 13.3% respectively. Decrease after Adrenoxyl was greater in wounds where bleeding occurred predominantly from small vessels. A less marked decrease occurred from 3 wounds of control rabbits produced 5 days after incisions of the opposite ear and without using Adrenoxyl. Hematologic examinations demonstrated a rise in the platelet count which might explain this observation.

Effect of low protein and plasmapheresis on fluid compartments and glomerular filtration rate MARJORIE B ZUCKER, LOUIS CIZEK (by invitation) and DOUGLAS TOMPKINS (by invitation) *Dept of Physiology, College of Physicians and Surgeons, Columbia Univ, New York City* Weekly measurements were made on 3 dogs on a control diet of Beacon Meal alone, and then after 3 weeks on a diet supplying 16 gm protein/kg/day and 80 Cal/kg/day (50% Beacon Meal, 16% dextrose, 33% Mazola, 0.5% NaCl, 0.2% yeast, 0.4 gm/kg/day Cal-C-Tose, 0.4 drops/kg/day oleum percomorph). Finally, determinations were made for several weeks during which the diet was continued and the dogs plasmapheresed 1 to 4 times. Including a weekly supplement, the NaCl intake approximated 20 mEq/kg/week. Clinical edema was not observed. The first number in following parentheses represents percentage change from the control value in dog 1, the second in dog 2, etc. The diet alone caused weight loss (-17, -13, -4), decreased serum protein concentration (-10, -6, -10), electrophoretic A/G ratio (-, -49, -34), colloid osmotic pressure (COP) (-8, -13, -16), T-1824 plasma volume (PV) (-23, -23, -26), creatinine clearance (GFR) (-26, -30, -46) and, in 2 dogs, reduced thiocyanate space (AF) (-21, -23, -). The latter is contrary to Keys' results in man on a famine diet. The results after plasmapheresis, expressed as percentage change from the values observed on the low protein diet, are given for the week during which the lowest COP was observed, and were determined at least 2 days after bleeding. Plasmapheresis did not alter the weight (-3, 0, 0), but usually reduced the serum proteins (-16, -, -11), A/G (-, +10, -34) and COP (-31, -32, -27). PV increased (+10, +5, +23), a finding which is difficult to explain. The maintenance of the GFR at a low level (-10, -15, +3), is of interest. AF increased (+12, +16, -), indicating that fluid retention occurred although COP was not reduced to values associated with clinical edema.

Hepato-renal factors in circulatory homeostasis XXVI **Effect of adrenalectomy on renal VEM system and hypertension** BENJAMIN W ZWEIFACH and EPHRAIM SHORR *Dept of Medicine, Cornell Univ Medical College and The New York Hospital, New York City* The formation of a vasoexcitor principle (VEM) by kidney appears to depend on the presence of the adrenal cortex, kidneys from adrenalectomized animals failing to produce VEM *in vitro*. The present study deals with attempts to produce renal hypertension in adrenalectomized rats maintained on a high salt diet in apparently good health for periods of 30 to 120 days. Various methods for inducing hypertension were employed, capping of one or both kidneys with gauze-collodion, partial ligation of the renal

artery, or figure-eight loop around the kidney. These experimental procedures, which produced hypertension in about 75 to 85% of the control rats, did not induce any clear-cut hypertension in a comparable series of 45 adrenalectomized rats maintained on salt. Microscopic observations on the mesoappendix of these latter animals showed no vascular hyperreactivity such as occurs in the terminal arterioles and precapillaries of hypertensive rats. There was also no hypertrophy of the blood vessels of the mesenteric capillary bed such as we have found to occur during the development of hypertension in rats. A previous study has shown that kidneys of hypertensive animals develop a metabolic lesion as a result of which VEM production, normally limited to anaerobiosis, now takes place aerobically as well as anaerobically. No such metabolic alteration was present in the kidneys of the adrenalectomized rats in this study. The relation of the content of renin in such kidneys and of the α_2 -globulin substrate in the blood of these animals will be discussed.

Muscular performance during positive radial acceleration LAURENCE E MOREHOUSE *Dept of Aviation Medicine, School of Medicine, Univ of Southern California, Los Angeles, Calif* Performance of pilots in a simulated cockpit on a human centrifuge was photographed by a motor driven high speed movie camera. Deviations in normal performance were studied. During acceleration, even at low levels, errors were repeated by trained subjects which would have marked effect on aircraft control. Physiological measurements of alterations in the functions of the nervous and muscular systems during positive radial acceleration indicate that, even at blackout g levels, normal function is intact. Errors in neuromuscular control, best shown by electromyographic records, suggested that alterations in proprioceptive sensations induced by g forces acting upon the moving segments played the major role in affecting performance.

Action potentials in single muscle fibers W L NASTUK and A L HODGKIN (introduced by M I GREGERSEN) *Dept of Physiology, College of Physicians and Surgeons, Columbia Univ, New York City, and the Physiological Laboratory, Cambridge, England* Graham and Gerard (*J Cell & Comp Physiol* 28: 99, 1946) and Ling (*Federation Proc* 7: 72, 1948) showed that the potential difference across the surface membrane of a resting muscle fiber could be measured directly by transverse impalement of the cell with a microelectrode. We have repeated these experiments using equipment capable of recording both action and resting potentials. Frog sartorius muscle, stretched in order to minimize movement, was stimulated either through its motor nerve or directly. Deflections in the record attributable to contraction were

often seen, but they did not appear until after the spike and under favorable circumstances might be absent altogether. Most of the experiments were carried out with electrodes which were filled with 3M KCl, but results qualitatively similar were obtained with electrodes filled with 0.118M KCl, but results qualitatively similar were obtained with electrodes filled with 0.118M KCl or with Ringer's solution. Electrodes filled with 3M KCl are believed to give the most accurate results since 1) junction potentials should be small, 2) electrode resistances are relatively low, 3) the quantity of KCl diffusing from the electrode during the time required for measurement can be shown to be negligible. In experiments at both 19°C and 7°C it was found that the action potential exceeded the resting potential in magnitude. It has been suggested that the membrane potential is reversed during activity because the membrane becomes selectively permeable to sodium during that period. If this is correct, one would expect that the membrane would cease to reverse its potential during activity if the sodium concentration in the external fluid is reduced to a low value. We have found that the resting potential and the action potential are approximately equal when the external sodium concentration is lowered to 30% of normal, and that over a considerable range the magnitude of the action potential is proportional to the logarithm of the external sodium concentration.

Adenosine phosphorylation by rabbit kidney homogenate DAVID RAPPORT, ATTILIO CANZANELLI, and RUTH GUILD (by invitation) *Dept of Physiology, Tufts College Medical School, Boston, Mass.* Rabbit kidney was homogenized in KCl NaHCO₃, and to the mixture was added MgCl₂ or SO₄ (0.01M), Na Succinate (0.01M), Na F (0.01M), and Sorensen phosphate buffer, (0.02M), the molarities representing final concentration. The final tissue dilution was 1:4. This was incubated aerobically alone or with added adenosine in final concentration of 0.03M, usually for 30 min at 37°. Phosphate and pentose were determined in the acid filtrate and in the barium and alcohol insoluble fractions. The evidence indicates that under our conditions adenosine, or one of its products, was phosphorylated, and that in the course of this phosphorylation, pentose disappeared. The resulting phosphate ester was not a mononucleotide, such as was reported by Colowick, Kalckar and Cori (*J Biol Chem* 137:343, 1941). The failure to find adenylic acid indicates that animal tissue behaves differently in this respect than yeast (Oster and Tersakowec, *Zeitschrift f. physiol Chem* 250:155, 1937). The results suggest that a mechanism similar to that described by Schlenk and Waldfogel (*Arch Biochem* 12:181, 1947) may be operating.

An enzymatic reaction involving amino acids and adenosine triphosphate JOHN M. REINER *Dept of Physiology, Tufts College Medical School, Boston, Mass.* In the search for an intermediate of peptide bond formation, the direct phosphorylation of amino acids by adenosine triphosphate was attempted. When a rat liver homogenate in isotonic KCl is incubated for 15 minutes at 37°C with 10 micromoles of adenosine triphosphate and 10 to 20 micromoles of amino acid, a labile phosphate compound is formed. With more prolonged incubation, the labile phosphate decreases, appearing as inorganic phosphate. A washed 'mitochondrial' fraction of the homogenate contains the activity, requires as a cofactor MnSO₄, the optimal concentration being 0.0016M, and inorganic phosphate. No labile phosphate is formed in the absence of amino acid, in the absence of adenosine triphosphate, or in the presence of only catalytic amounts of the latter. Activity has been obtained with glycine, methionine, arginine, histidine, tryptophan, and aspartic acid. The activity increases with increasing amounts of enzyme and of adenosine triphosphate. Activity is inhibited by 2,4-dinitrophenol. The product is extremely labile at pH 4 it is destroyed in 30 minutes at room temperature, and the hydrolysis is accelerated by molybdate, cold 5% trichloroacetic acid splits it within a minute or two, so that deproteinization must be performed with saturated ammonium sulphate. Negative results have been obtained with Lapmann's hydroxylamine reagent for acyl phosphates. This suggests that an N-phosphoamino acid may be involved, however, since it is not known how the adjacent amino group would affect the reaction of an acyl phosphate with hydroxylamine and the color formation with ferric ion, the alternative possibility cannot be ruled out.

A new blood supply for ischemic hearts, by connecting the aorta with the coronary vessels JOSEPH THOMAS ROBERTS *Univ of Buffalo School of Medicine, Buffalo and Veterans Adm Hospital, Batavia, N. Y.* The concept of revascularizing ischemic hearts by bringing aortic blood to the myocardium through the coronary sinus and veins was introduced earlier by the author. Since then others have confirmed his report that such revascularization inhibited myocardial infarction after ligation of the coronary arteries. This operation devised by the present author is now being applied to human patients suffering from myocardial ischemia. Subsequent studies on the procedure are brought up to date, as are efforts to anastomose the internal mammary artery with the coronary arteries and veins. It is predicted that this operation may become a useful method of treating the coronary artery disease problem. After such anastomosis, myocardial blood is apparently drained by the Thebesian vessels as well as by other routes.

Initial effects of potassium on the mechanical responses of skeletal muscle ALEXANDER SANDOW and ARTHUR J. KAHN (by invitation) *Washington Square College of Arts and Sciences, New York Univ., New York City* The present studies (supported by a grant from the Office of Naval Research under Contract N6on-279, Task order 7) deal with changes in the latency relaxation (LR) and peak tension (T) of isometric twitches of the frog sartorius immediately after immersion of the muscle in K-enriched Ringer's solution. Square-wave, massive, transverse shocks, applied to the muscle immersed in the test solution, are used as stimuli. The LR is recorded by the piezoelectric, cathode-ray method, and T by optical myography. During an initial period of 3 to 4 minutes after placing a muscle in a solution containing 28 mg % K, both the magnitude (R) of the LR and T increase. The alterations are reversed relatively slowly after the initial period, although T does so somewhat more slowly than R. At the end of the initial period, the maximal increases, when compared with responses in normal Ringer's (7.8 mg % K), are approximately R, 100% and T, 25%. Solutions containing some 50 mg % K or greater cause only immediate decreases in R and T, although initial increases, too fleeting to observe, may have occurred. The initial increases observed with the smaller potassium concentrations develop so rapidly, before any appreciable K had accumulated intracellularly, that it is inferred the added K could only have directly affected the behavior of the membrane excitatory mechanism. This view will be discussed in relation to the significance of the LR in the process by which excitation and contraction are linked in the response of the muscle fiber.

Action potentials of giant fibers of the crayfish, *cambarus clarkii* C. A. G. WIERSMA *Kerckhoff Labs of Biology, California Inst of Technology, Pasadena, Calif* Action potentials lead off from partially or totally isolated giant fibers of the central nervous system almost invariably show instead of a single phase under one electrode, a double phased deflection. The first phase is always positive, and depending on leading off conditions, varies in size from very small to as large as the subsequent negative deflection. All trials to account for this positive deflection as an artifact or a pick up of a distant potential by the inactive electrode, have thus far failed. Especially convincing for the independent nature of the positive deflection which occurs under the active electrode were experiments in which both leads were taken from a part of an isolated fiber, completely surrounded by oil. Under these circumstances there will be at first a diphasic potential with a monophasic lead (quadrupole phasic with bipolar leads). After a short time in oil the negative phase becomes smaller and disappears, leaving a large positive variation. On re-submerging of the fiber in physiological fluid and subsequent return to oil this order of events can be repeated several times. In fiber bundles a diphasic deflection remains under these circumstances, only the isolated giant fibers show this phenomenon. As a working hypothesis it may be supposed that these fibers contain two double layers of opposite sign. The inner, which would be responsible for the positive deflections, would use the very fluid interior axoplasm as a conductive medium and would hence not be influenced by the increase in outside resistance caused by oil.

THE AMERICAN SOCIETY OF BIOLOGICAL CHEMISTS, INC.

Fortieth Annual Meeting

DETROIT, MICHIGAN, April 18-22, 1949

(For possible corrections in any of the following abstracts see the June issue)

Phenolsulfatase of animal tissues LYNN D ABBOTT, JR and MARY K EAST (by invitation) *Dept of Biochemistry, Medical College of Virginia, Richmond, Va* In order to establish more precisely the optimal conditions for the determination of animal phenolsulfatase activity, we have determined pH-activity curves with rat liver and kidneys and temperature-activity curves with rat liver using *p*-nitrophenylsulfate as substrate. The optimum pH appears to be slightly higher (about 6.6) than that of the phenolsulfatase of takadiastase (6.2). As was previously noted with the takadiastase enzyme, the rate of reaction was much greater at 50° than at 37°C. We have studied the phenolsulfatase activity of the sera and livers of normal rats, carbon tetrachloride-poisoned rats, and rats exposed to CCl₄ but protected by xanthine injection. The data indicate that the serum phenolsulfatase activity of carbon tetrachloride-poisoned rats was greater than that of control animals or of protected animals. The phenolsulfatase activity of the liver of carbon tetrachloride-poisoned rats appeared to be decreased.

Effect of uric acid on the peroxidative detoxification of diphtheria toxin KJELL AGNER (introduced by J W WILLIAMS) *Dept of Chemistry, Univ of Wisconsin, Madison, Wis* It has been previously reported (*Fed Proc* 7:140, 1948) that crude diphtheria toxin preparations are detoxified by peroxidases in the presence of H₂O₂. Purified toxin was not detoxified in experiments performed under similar conditions. The reaction required the presence of a dialyzable substance or substances present in the crude culture filtrate of diphtheria bacilli. It has now been found that the above crude filtrate can be replaced by a dilute solution of uric acid. Verdoperoxidase as well as horse radish peroxidase oxidize uric acid in the presence of low concentrations of H₂O₂. The rate of the destruction of uric acid is increased by the addition of diphtheria toxin. It seems likely that an intermediate oxidation product of uric acid reacts with the toxin to give detoxification.

Antimycin antibiotics KAMALUDDIN AHMAD (by invitation), F MERLIN BUMPUS (by invitation), B R DUNSHEE (by invitation) and F M STRONG *Dept of Biochemistry, College of Agriculture, Univ of Wisconsin, Madison, Wis* A new antibiotic, antimycin A, has been isolated from cultures of a

Streptomyces species. Antimycin A is a nitrogenous phenol of the probable formula C₂₅H₄₀O₆N₂. Alkaline hydrolysis destroys the antibiotic activity, and gives rise to a nitrogenous phenolic acid, a neutral, nitrogen-free product, and two moles of a volatile fatty acid. Antimycin A is highly toxic to many yeasts and other fungi, but is relatively inactive toward bacteria. Its effect on several of the more sensitive organisms is easily observable at concentrations of a few parts per billion. It inhibits the respiration of *Saccharomyces cerevisiae* Y30 and stimulates aerobic fermentation up to the anaerobic rate. It also inhibits the cytochrome oxidase and succinic dehydrogenase activities of rat liver homogenates at concentrations in the range of 10⁻⁶ molar. Paper chromatography of crude extracts of the original culture filtrate reveals the presence of two additional antibiotics, provisionally designated as Antimycin B and C.

Abnormal excretion of tryptophane-like substances in tuberculosis ANTHONY A ALBANESE, L EMMETT HOLT, JR, MARILYN LEIN (by invitation), EMILIE M SMETAK (by invitation) and BETTY VESTAL (by invitation) *Dept of Pediatrics, New York Univ College of Medicine, New York City* By the application of the tryptophane and amino N methods developed by some of us to the urines of patients of both sexes the following data were obtained:

Clin diag	Age group	No. of det.	Tryptophane amino N Total amino N, %
Non tubercular	3 m - 15 yr	55	2.6 ± 1.0
	2-14 yr	20	3.4 ± 0.7
	18-40 yr	48	4.5 ± 0.6
Tubercular	3-13 yr	32	6.7 ± 1.0
	20-62 yr	9	7.1 ± 0.8

Successive measurements on patients over a period of 2-3 years gave the impression that a) the T A N / A N ratios are consistently higher for chronic than for acute forms of tuberculosis, b) critical episodes are characterized by sharp increases in the ratio, whereas recovery is accompanied by a decrease in this value, and c) the abnormal T A N / A N ratios are not due to febrile

states Comparable T A N /A N ratios derived from urinary tryptophane figures obtained by the microbiological or Shaw-McFarlane techniques did not yield differentiating values for the tuberculosis patient as found by the Albanese-Frankston method. Moreover the high ratios do not arise from an increased output by the tubercular subject of a non-diffusible bound N component. This however does not exclude a possible increase in the output of diffusible bound N. The metabolic and nutritional implications of these observations will be discussed.

Biological value of wheat and corn proteins in the male infant. ANTHONY A. ALBANESE, L. EMMETT HOLT, JR., SELMA E. SNYDERMAN (by invitation), MARILYN LEIN (by invitation), EMILIE M. SMETAK (by invitation) and BETTY VESTAL (by invitation) *Dept. of Pediatrics, New York Univ. College of Medicine, New York City.* During the past year we have made measurements on the food value of some vegetable proteins in the infant. We felt this worthwhile for two reasons, a) vegetable protein containing diets might prove useful in feeding infants allergic to animal protein diets and, b) the use of vegetable protein diets might prove necessary if predictions regarding the failure of future food production to keep pace with population growth are realized. A synthetic diet containing lysine reinforced granulated wheat gluten (4% lysine content) as the principal N component was found to support N retention, body weight gains and blood protein concentration in 3 male infants equal to those achieved with an evaporated milk formula fed at comparable N, caloric and fluid levels. On the other hand a similar diet fed under similar conditions in which corn gluten reinforced with 6% L-lysine and 1% L-tryptophane constituted the principal protein component was found not to support N retention and weight gains at levels comparable to those attained with the evaporated milk formula. The inferior biological value of the corn gluten diet was not due to poor digestibility which we had previously found to be cause of the poor nutritional quality of commercial zein. In the light of recent investigations on the effects of amino acid imbalance on the growth of experimental animals reported from various laboratories we venture to suggest that the inferior nutritional quality of reinforced corn gluten in the infant may arise in part from its failure to provide an amino acid pattern compatible with growth.

Isolation of adenosine triphosphate from plant tissue. H. G. ALBAUM, M. OGUR (by invitation), and A. HIRSHFELD (by invitation) *Depts. of Biology and Chemistry of Brooklyn College, Brooklyn, N. Y.* We have previously reported (*Fed. Proc.* 7:141, 1948) an adenine-pentose-pyrophosphate in trichloroacetic acid extracts of the mung bean. The isolation of adenosine triphosphate (ATP) from a

plant source, seemed a necessary experimental step in the extension of common pathways of metabolism to plant tissues. The present work deals with the isolation of the plant ATP with a minimum purity of 70% when calculated as $\text{Ba}_2\text{ATP} \cdot 4\text{H}_2\text{O}$. A trichloroacetic acid extract of mung bean sprouts was fractionated with barium into two soluble fractions (pH 4.5-8, and pH 1-4.5), and a residue insoluble at pH 1. Approximately 80% of the material showing ultraviolet absorption at 260 $m\mu$ was found in the fraction insoluble at pH 1. This material, which may be dissolved and freed of barium by sodium sulfate exchange, represents an ATP extract of approximately 10% purity. Precipitation of the silver salt, decomposition with HCl, and reprecipitation of the barium salt increased the purity to approximately 50%. This barium salt is pigmented and shows absorption maxima at 320 $m\mu$ as well as at 260 $m\mu$. Removal of the barium by ion exchange, using Amberlite IR 100, and treatment with four volumes of acetone yielded a white barium salt with no absorption at 320 $m\mu$. This preparation has a ratio of pentose:adenine:labile P:total P of 1:1:2:3 and a minimum purity of 70%. It is active in the transphosphorylation of glucose by yeast hexokinase. After treatment with myokinase and hexokinase, it is deaminated by a muscle deaminase at a slow rate compared with animal ATP.

In vitro inhibition of hyaluronidase activity. HARVEY E. ALBURN, ROBERT W. WHITLEY and LOUISE C. HALL (introduced by SAM SEIFTER) *Wyeth Institute of Applied Biochemistry, Philadelphia, Pa.* In order to study the nature and amount of hyaluronidase inhibitor present in hyaluronic acid preparations, the inhibition by heparin and other sulfated polyuronides and the neutralization of this inhibition by salts and protamine were investigated. The hyaluronidase activity was determined by a modification of the Kass and Seastone turbidimetric method and a highly purified hyaluronic acid from human umbilical cord was used as the substrate. With 0.1 mg of hyaluronate and sufficient hyaluronidase to hydrolyze it almost completely in 1 ml of pH 6.0, 0.1 M potassium acetate buffer in 30 min, 0.0033 gamma of heparin gave detectable inhibition and 0.33 gamma gave maximal inhibition in the absence of sodium chloride. In the presence of 0.075M sodium chloride, the optimal concentration, 10 gamma of heparin was required to give detectable inhibition. Similar data were obtained for other salts and other polyuronides. These data were used to calculate the amounts of inhibitor in various hyaluronate preparations. Protamine was found to neutralize the inhibition of hyaluronidase by heparin in very low concentrations, probably due to combination with the heparin. In higher concentrations protamine was found to inhibit hyaluronidase activity.

Effects of 2-acetylaminofluorene on liver func-

tion JAMES B ALLISON, ARTHUR W WASE (by invitation) and WALTER W WAINIO (by invitation) *Bureau of Biological Research, Rutgers Univ, New Brunswick, N J* Studies are underway on the effects of the carcinogenic agent, 2-acetylaminofluorene, on liver function in dogs and rats. The animals are being fed a synthetic diet (*J Nutrition* 29 413, 1945) consisting of casein 12%, lard, carbohydrate, agar, minerals, synthetic vitamins and 0.03 to 0.05% 2-acetylaminofluorene. Preliminary results on the dogs demonstrate that after 4 months subsistence on this diet the excretion of uric acid increased markedly while the excretion of allantoin decreased, changes which have been associated with decreased uricase activity in damaged livers. Decreased liver function was indicated also by an increased retention of bromsulfalein, and by jaundice. At the end of 6 months a hepatoma had developed which was sufficiently advanced in 1 dog to cause death. The neoplasm had spread also to the spleen in this animal. The correlation between these and other metabolic changes associated with the development of hepatomas are being followed together with the retention of nitrogen in the body of the animal.

Administration of parenteral and oral casein hydrolysates to depleted dogs. CARL ALPER (by invitation), BACON F CHOW and SHIRLEY Q DELBRASE (by invitation) *Nutrition Dept, Div of Development, and the Div of Protein Chemistry, The Squibb Institute for Medical Research, New Brunswick, N J* Mongrel dogs, previously depleted by feeding a protein-free diet at normal caloric intake, with or without the accompaniment of plasmapheresis, were fed parenterally for a period of four weeks, and then orally for a similar period, a tryptic digest of casein as the sole source of nitrogen at a level sufficient to maintain positive nitrogen balance. The object of this experiment was to study the effectiveness of parenterally and orally administered casein hydrolysates in the repletion of plasma protein, and the maintenance of positive N balance. Maintenance of N balance, and the repletion of plasma protein were measured by urine, fecal, and blood protein N determinations and blood-volume determinations. Results of these experiments, which were carried out in 10 dogs, showed 1) no striking increments in weight during repletion, and 2) dogs retained 2 to 3-fold more N via the oral route than via the intravenous route, even though partial repletion had already been effected by the intravenous route. Also it was observed that, contrary to the current belief, the degree of hydrolysis varying from 18 to 40% did not appear to influence the utilization of N. Between 5-9% of the N retained by parenteral feeding was utilized for plasma protein synthesis. About 15-25% of the N retained by oral feeding was utilized for plasma protein synthesis.

Microbially synthesized APF (animal protein factor) STEFAN ANSBACHER, HARLEY H HILL, JR (by invitation), JESSE W TIEMAN (by invitation), JEAN F DOWNING (by invitation) and JOHN H CALDWELL, JR (by invitation) *Research Laboratory, Vi-D-Co, Marion, Ind* The need of single-stomached animals for APF appears to increase when increasing amounts of soybean oil meal (SBOM) are fed. It would seem logical, therefore, to impart APF potency to SBOM. This has been accomplished by growing certain micro-organisms on media, the principal constituent of which was SBOM. Yeast, although an excellent source of the vitamin B-complex, has normally no APF activity, but it too may be endowed with high APF potency by certain fermentation processes. The micro-organisms that selectively synthesize APF have been isolated for use in these processes. The physiological activity is expressed in APF units. Fish meal, fed to chicks at a level of 5% of the basal (all-plant) ration, has been assigned a potency of one unit. If a product fed at the same level causes chicks to grow approximately as well as those receiving the fish meal ration, it has a potency of one unit. The potency is two units, if the oral administration of a product at 2½% results in growth about equal to that obtained from the fish meal ration. Products containing at least 20 APF units have been obtained by fermentation processes without resorting to chemical purification procedures.

Chromatography of urinary steroids and products of acid hydrolysis of pure steroids. R M ARCHIBALD *Hospital of the Rockefeller Institute for Medical Research, New York City* CCl_4 extracts of hydrolysates of 10 to 50 cc urine have been chromatographed on columns in a Technicon fraction cutter. Eluting agents used were benzene, benzene plus 0.1%, 0.5%, and 2.0% ethyl alcohol, 95% ethyl alcohol, water, and 50% pyridine in water. Ultraviolet absorptions at 215, 240, 260 $\text{m}\mu$ were determined on each of ninety 3 cc fractions, then aliquots of each were used for Zimmermann, Liebermann-Burchard and modified Kober (color and fluorescence) reactions, and the colorimetric method of Munson, *et al* for dehydroisoandrosterone. By these methods comparisons were made of chromatograph fractions of extracts obtained after hydrolysis of pure steroids and urines with HCl , H_3PO_4 , H_2SO_4 , or NaOH a) at room temperature b) after reflux boiling 30 minutes. Application of these techniques to urine of a woman before and after surgical removal of a hirsutizing adrenal tumor, and to an extract of the tumor, indicated the presence of a large amount of material easily eluted with benzene in the tumor and in the urine prior to operation, but absent from urine after operation.

Determination of dimethylethanolamine in biological materials. CAMILLO ARTOM and MARIETTA CROWDER (by invitation) *Dept of Biochemistry,*

Bowman Gray School of Medicine, Winston-Salem, N C The method is based on the observation that dimethylethanolamine (DME), a likely intermediate in choline metabolism, is rapidly and quantitatively displaced from its alkaline solutions by steam distillation. The protein-free material is treated with HNO_2 to destroy primary and secondary amines, transferred to the distilling flask of the Parnas-Wagner apparatus, brought to pH 10, and aerated at room temperature to remove volatile tertiary amines. DME is then steam distilled for 15 minutes into an excess of standard acid and the excess acid titrated iodometrically with 0.005 N $\text{Na}_2\text{S}_2\text{O}_3$. 95 to 100% of the substance in pure solutions or added to tissue extracts could be recovered. Choline, ethanolamine, methylethanolamine, serine, urea, glycine, betaine or trimethylamine do not interfere appreciably. The method has been applied to aqueous extracts of liver and muscle, deproteinized with colloidal $\text{Fe}(\text{OH})_3$, and to acid hydrolysates of the lipides, extracted from the tissues of rats under various dietary conditions. Traces of DME were found only occasionally, the results being negative in most determinations. However, quite definite amounts of DME were detected in the liver lipides of rats, killed 3 or 6 hours after the administration of a single large dose of the compound. This finding indicates that DME can be incorporated in the phospholipide molecule even before further methylation to choline. Determinations of DME in the tissues of animals receiving large doses of choline or ethanolamine are in progress.

Response of pteroylglutamic acid (PGA) depleted rats to supplementation with natural products CONRADO F. ASENJO *Dept. of Chemistry and Nutrition, School of Tropical Medicine, San Juan, Puerto Rico* PGA-depleted rats, 7 weeks old, were continued on the highly purified PGA-free diet, containing 2% succinylsulfathiazole, but, in addition, were given daily weight amounts of natural products for a period of 5 consecutive weeks. The amount of the supplement was never more than 2 gm, so as not to interfere to any great extent with the basal diet intake. Two % by weight of SST was mixed with the daily supplement. Growth response, white cell regeneration, degree of alopecia, and spleen condition were recorded at the end of the supplementation period. As the depleted rat requirement of PGA to regain normalcy is approximately known (*J. Nutrition*, 38: 601, 1948), the response exhibited to the different supplements by the depleted animals can be evaluated roughly in terms of PGA. Of 10 fresh tropical fruits so far assayed, the only one to exhibit appreciable curative action on the rat was the avocado. Boiled and dried pigeon peas, red kidney beans, and breadfruit seed proved to be rich sources of PGA, inducing very rapid and pronounced recovery. In the present

report the results obtained with 20 natural products commonly used in the West Indian dietary, especially tropical products, are presented.

Action of ribonuclease on ribonucleic acid JAMES E. BACHER (by invitation) and FRANK WORTHINGTON ALLEN *Div. of Biochemistry, Univ. of California Medical School, Berkeley, Calif.* Ribonucleic acid from yeast was purified and dialyzed, neutralized to pH 7.0 and subjected to ribonuclease action. Dialysis was continued and the dialyzable and non-dialyzable fractions were isolated by lyophilization. Control experiments without enzyme were treated similarly. Application of rate studies to fractions that were isolated gave the following data:

	Ribonucleic Acid	Control Na salt	Dialyzable Fraction	Non-dialyzable Fraction
	%	%	%	%
Total N	15.4	13.7	12.3	13.7
Guanine N				
Total N	34.3	34.9	24.6	39.2
Purine N				
Total N	67.9	67.4	53.8	73.0
Total P	9.0	8.2	8.3	7.8
Labile P				
Total P	50.6	51.2	34.6	57.3
Stable P				
Total P	49.4	48.8	65.4	42.7
	atoms	atoms	atoms	atoms
Purine N	5.06	4.89	5.11	4.98
Labile P				
Pyrimidine N				
Stable P	2.44	2.48	2.32	2.47

Ribonucleic acid contains approximately equivalent quantities of each nitrogenous constituent. After ribonuclease action the dialyzable fraction, which comprises 25%, contains 2 pyrimidines per purine, more adenine than guanine and approximately twice as much uracil as cytosine. The non-dialyzable fraction, which comprises 70%, reflects the contrary.

Transaminase activity in the skeletal muscles of normal and vitamin E-deficient animals MARY ALICE BARBER (by invitation), DANIEL H. BASINSKI (by invitation) and H. A. MATILL *Dept. of Biochemistry, State Univ. of Iowa, Iowa City, Iowa* To examine further into the altered energy metabolism accompanying the dystrophy of vitamin E deficiency, aspartic α -ketoglutaric transaminase activity was investigated in skeletal muscle homogenates from normal and E-deficient guinea pigs and rabbits. In dystrophy, this trans-

amination reaction was decreased by $\frac{1}{2}$ in guinea pigs and by $\frac{1}{3}$ in rabbits. The diminution of activity was consistent whether the results were calculated on the basis of wet weight of the tissue or on the dry weight or N content of the homogenate. The concentration of the coenzyme, pyridoxal phosphate, appeared not to be the limiting factor. The reduced activity was not an artifact produced by altered removal of the oxalacetic acid formed. On the contrary, normal muscle seemed to possess a better alternative mechanism for disposing of excess oxalacetate than did dystrophic muscle. The significance of these results in the interpretation of the abnormal energy metabolism of these paralyzed muscles is briefly discussed.

Intracellular heterogeneity of liver ribonucleic acid as evidenced by P^{32} uptake. CYRUS P. BARNUM and ROBERT A. HUSEBY (by invitation), *Depts. of Physiological Chemistry and Physiology, Univ. of Minnesota Medical School, Minneapolis, Minn.* From fasted, homogenized mouse livers ribonucleic acid (RNA) has been isolated from the nuclei (N-RNA), the cytoplasmic particulate fractions (M-RNA), and the cytoplasmic fraction that does not sediment in 90 minutes at 23,000 *g* (MS-RNA). The mice had been injected intraperitoneally with inorganic P^{32} at times varying from 15 minutes to 24 hours prior to sacrifice. The N-RNA shows a specific activity (S.A. -disintegrations/min./ γ total P) which rises rapidly so that at 1 hour it is 14% of the S.A. of tissue inorganic P (I.P.) as compared to cytoplasmic phospholipid P for which the S.A. is 10.5% that of I.P. The S.A. of N-RNA passes through a maximum around 3 hours and is below that of phospholipid at 6 hours. The M-RNA takes up P^{32} very slowly and at 1 hour its S.A. is only about 0.6% that of N-RNA but rises to 3.1% at 3 hours and 21.5% at 20 hours. No significant differences have been observed in the S.A. of M-RNA samples obtained from mitochondria (sedimented in 5 minutes at 23,000 *g*) or microsomes (sedimented in 90 minutes at 23,000 *g*). The MS-RNA follows a S.A. time curve intermediate between those of N-RNA and M-RNA. At 1 hour its S.A. is about 6.8% that of N-RNA while at 3 hours it is 9.1% and at 20 hours 30.5%. These data point up the relationship between intracellular location of RNA and its rate of incorporation of newly administered inorganic phosphate.

Anterior pituitary growth hormone preparations and the glutamine-glutaminase system. PAUL D. BARTLETT (introduced by OLIVER H. GAEBLER), *Edsel B. Ford Institute for Medical Research, Henry Ford Hospital, Detroit, Mich.* Van Slyke *et al.* (*J. Biol. Chem.* 150: 481, 1943) have shown that transport and storage of ammonia are physiological functions of glutamine. Storage of amino nitrogen might be another function, and, in this respect,

glutamine might be considered a major constituent of Schoenheimer's 'metabolic pool' of nitrogen. Since in this and other laboratories weight gain and nitrogen storage have been produced in rats and dogs with growth hormone preparations it seemed of interest to study the *in vivo* effect of the recent Fishman, Wilhelm, Russell preparation on the glutamine-glutaminase system. In 19, 20, and 28 day experiments on dogs 3 different lots of this preparation were tested. Increases in plasma glutamine of 19, 30, and 33% above the average control level were obtained. Nitrogen storage and weight gain were produced and excretion of urinary ammonia was found to parallel changes in plasma glutamine. Experiments now in progress will determine whether or not the increase in plasma glutamine occurs independently of total free amino acids. In *ad libitum* feeding experiments on hypophysectomized rats and on hypophysectomized rats treated with growth hormone glutaminase assays of 21 and 31 μ /ml of 25% kidney emulsion respectively were obtained. Food consumption of treated rats did not increase during the 7-day experimental period. Kidneys from normal rats maintained on a food intake based on that of the hypophysectomized-treated rats and from normal rats fed *ad libitum* assayed respectively 35 and 56 μ /ml of 25% emulsion.

Behavior of the thyroid toward elements of the seventh periodic group II Rhenium. EMIL J. BAUMANN, N. ZIZMER (by invitation), ELEANOR OSHRY (by invitation) and S. M. SEIDLIN (by invitation), *Laboratory Div. and Laboratory of Medical Physics, Montefiore Hospital, New York City.* Two years ago we presented experiments to the Society which showed that the thyroid filters not only I from the circulation but other halogens as well. We expressed the view that the thyroid distinguishes between the halogens imperfectly if at all in the filtration process. Further, it was suggested that if a very large amount of one of the halogens were administered, compared to the amount of any of the other halogens ingested, the one given in excess will tend to wash the others out of the thyroid in a mass action like effect. On the basis of other work, we postulated then that other elements of group VII of the Periodic Table would behave as the halogens do and we now report our experiments with Rhenium (element 75). Perrhenic acid given parenterally to rats and rabbits was found to accumulate in the thyroid in greater concentration than in any other tissue—25 to over 100 times more than in the tissue having the next highest concentration. The maximum concentration occurs 1 to 4 hours after injection. Most of the Re is excreted in the urine during the first day and the remainder is practically all eliminated in the next 24-hour period.

Effects of glucose, bile salts, and protein on re-

covery of neutral 17-ketosteroids WILLIAM T BEHER (by invitation) and O H GAEBLER *Edsel B Ford Institute for Medical Research, Henry Ford Hospital, Detroit, Mich* Rates of color development of individual 17-ketosteroids, and effects of varying other conditions in the Zimmermann reaction, have been studied extensively (*Endocrinology* 33 189) Little attention has been given to effects of normal and pathological constituents of bile and urine on recovery of 17-ketosteroids In studying this problem, we have used a method involving the usual hydrolysis and continuous extraction The Zimmermann reaction was then applied after removing the estrogens, or after separating the neutral 17-ketosteroid fraction with Girard's reagent, according to the general scheme outlined by Pincus (*Clinical Endocrinology* 5 291) In either case, 2 color spectrophotometry was the final step Additions of glucose to solutions of free 17-ketosteroids (androsterone and dehydroisandrosterone), or to urine, did not influence the results Addition of bile salts or purified human serum albumin to solutions of free 17-ketosteroids did not affect the results when solutions were analyzed without preliminary hydrolysis, but lowered them when hydrolysis was included Low values due to addition of protein could be overcome by doubling the extraction period, but bile acids apparently increased the destruction of ketosteroids during hydrolysis, so that longer extraction did not influence the result Analysis of urines with and without addition of bile salts or purified human serum albumin showed that the same findings apply when one deals with conjugated 17-ketosteroids Effects of ultrafiltering to remove protein, and of varying the acid used in hydrolysis, were also studied

Intravenous administration of commercial cytochrome C to rats previously treated with radioactive iron HELMUT BEINERT and KURT R REISSMANN (introduced by FRED W OBERST) *USAF School of Aviation Medicine, Randolph Air Force Base, Texas* The biosynthesis of iron-labeled cytochrome c showing a radioactivity suitable for tracer studies has been reported previously (*Science* 108 634, 1948) Experiments were made to obtain knowledge about the penetration of injected cytochrome c into tissue cells Two pairs of litter-mate rats previously treated with radioiron were nephrectomized unilaterally One animal of each pair was then injected intravenously with commercial cytochrome c (8 mg) Immediately thereafter, both pairs were taken to a simulated altitude of 20,000 ft to favor utilization of injected cytochrome, if such actually does occur All animals were sacrificed 24 hours after injection, to assure return of tissue cytochrome concentration to pre-injection level Kidneys, hearts, and skeletal muscle were assayed for cytochrome concentration

and the isolated cytochrome was checked for radioactivity Comparative tests showed that the cytochrome content per unit weight of the left and right kidney removed under the conditions of the experiment generally does not differ by more than $\pm 5\%$. Unilateral nephrectomy, therefore, represents a useful means of internal control By this technique and comparison with the control litter-mates no significant elevation of the cytochrome values in the organs of the injected animals was found, indicating that no appreciable quantity of cytochrome was left in intercellular spaces No significant dilution of the originally occurring radioactive cytochrome could be demonstrated in the cytochrome-injected animals Iron analysis indicates that at least 94% of the measured radioactivity is due to cytochrome iron This experiment does not give evidence of any significant incorporation of injected cytochrome c into tissue cells

The fate of ingested uric acid in man AARON BENDICH (by invitation), WILLIAM D GEREN (by invitation), OSCAR BODANSKY and GEORGE BOWORTH BROWN *The Sloan-Kettering Institute for Cancer Research, New York, N Y* A normal male ingested 150 mg of uric acid labeled with an excess of N^{15} in positions 1 and 3 Total urine collections were made over specific periods for 7 days and were analysed for total nitrogen, uric acid, urea and ammonia For isotopic nitrogen analyses, uric acid was isolated by adsorption on Norite, elution with dilute alkali and purified by repeated crystallization Urea was obtained as the dixanthidol derivative and urinary ammonia was isolated The course of the urinary excretion of each of the stated compounds, as well as their isotope content, was determined During a period of 4 days, 80% of the administered isotope appeared in the urine Of this amount, about $\frac{1}{4}$ was present as urea N and about $\frac{1}{4}$ as uric acid N The results are discussed with respect to the question of uricase in human tissues, to bacterial action in the intestine, and to the relative contribution of purine nitrogen to urinary urea and uric acid nitrogen

Human uric acid metabolism JEAN D BENEDICT (by invitation), PETER H FORSHAM (by invitation) and DEWITT STETTIN, JR *Dept of Biological Chemistry, Harvard Medical School, Dept of Medicine, Peter Bent Brigham Hospital, Boston, Mass, and the Div of Nutrition and Physiology, Public Health Research Institute of The City of New York, New York City* Uric acid has been synthesized in such a fashion as to include a high concentration of N^{15} in the pyrimidine ring and this material has been administered intravenously in tracer dose to human subjects while maintained in balance on a purine-poor diet From the concentrations of N^{15} in the urinary uric acid samples in the succeeding period it has been possible to estimate 1) the quan-

tity of uric acid which mixed with and diluted the injected isotopic uric acid, 2) the rate of *in vivo* formation of uric acid in man under these circumstances. These quantities have been compared with the prevailing level of plasma uric acid during the experiment and with the independently determined rate of urinary uric acid excretion. Experiments have been conducted on both normal subjects and patients suffering from gout.

Partial purification and properties of hydantoinase FREDERICK BERNHEIM, MARY L C BERNHEIM (by invitation) and G S EADIE (by invitation) *Depts of Physiology, Pharmacology and Biochemistry, Duke University Medical School, Durham, N C*. The enzyme in rat liver which hydrolyzes hydantoin to hydantoic acid has been partially purified by removing proteins insoluble in slightly alkaline and acid solutions and by dialysis. The enzyme remains in a clear solution 0.25 ml of which hydrolyzes under optimal conditions 4.0 mg of hydantoin in 15 minutes. The solution also contains an active esterase for simple esters but only traces of choline, demerol and procaine esterases. If the activity is measured by the liberation of CO_2 , the end point depends on the pH probably because of the simultaneous formation of an NH_2 group. That the end point at any pH corresponds to the quantitative formation of hydantoic acid was proved by the determination of the latter with the diacetyl monoxime reagent. The enzyme does not hydrolyze parabanic acid, dimethyl- or methyl ethyl hydantoin but they inhibit its action on hydantoin. Its pH optimum is about 8.6. The reaction is monomolecular throughout the greater part of the hydrolysis. The relation between initial velocity and substrate concentration is of the Michaelis-Menten type. Preliminary experiments indicate a dissociation constant not far from 0.01, showing relatively small affinity between enzyme and substrate.

Conversion of carotene to vitamin A by the rat J G BIERI (introduced by M O SCHULTZE) *Div of Agricultural Biochemistry, Univ of Minnesota, Minneapolis, Minn*. Further evidence for the conversion of carotene to vitamin A by hypothyroid rats is presented from studies of the blood serum vitamin A content of hypothyroid rats given carotene. Two of four groups of rats on a vitamin A-deficient ration were made hypothyroid by feeding 0.2% thiouracil. When the animals showed weight plateaus, definite xerophthalmia and no measurable serum vitamin A, 200 γ of B-carotene in Tween 80-water (1:1) was given weekly for 5 weeks orally or intramuscularly. Xerophthalmia disappeared. The hypothyroid rats gained weight for 15-19 days only, the others continued to gain. Vitamin A in blood serum determined by the method of Bessey before, and 12 hours after, the last administration of carotene showed the following:

Thyroid	Carotene	Serum Vitamin A, $\gamma\%$	
		Before	After
Normal	Oral	7.2	13.7
Hypothyroid	Oral	8.3	21.6
Normal	Intramuscul	7.0	10.2
Hypothyroid	Intramuscul	5.8	26.3

Several laboratories have reported that the small intestine is involved in the conversion of carotene to vitamin A by the rat. Preliminary studies show that vitamin A-deficient rats given 400 γ of B-carotene in Tween intramuscularly after surgical removal of the small intestine have in the blood serum, after 5 hours, appreciable amounts (equivalent to 12-50 $\gamma\%$ of vitamin A) of a fat soluble light-sensitive material absorbing at 328 m μ . Operated control rats given Tween show no appreciable change in serum fat-soluble components absorbing at 320-350 m μ .

Cystathionase FRANCIS BINKLEY *Laboratory for the Study of Hereditary and Metabolic Disorders, Univ of Utah School of Medicine, Salt Lake City, Utah*. The enzyme responsible for the conversion of cystathionine to a compound reacting in the test of Sullivan for cysteine has been obtained in a condition of high purification from rat and pig liver. The purified enzyme was obtained in crystalline form and was dissociated, under acid conditions, into an inactive crystalline protein and an alcohol-soluble coenzyme. The inactive protein was reactivated by incubation with the coenzyme or a boiled extract of liver at values of pH near 8. Magnesium ions and inorganic phosphate were required for the activity of the enzyme but it was not possible to demonstrate an uptake of phosphate in the reaction. The rate of reaction was dependent upon the concentration of inorganic phosphate as well as upon the concentration of cystathionine or enzyme. The enzyme was active in the desulfhydration of cysteine, inorganic phosphate was required for the desulfhydration of cysteine. Cysteine was not a primary product of the action of the enzyme on cystathionine, the product responded to the Sullivan reaction but not to the reaction of Nakamura and Binkley. If, however, the reaction product were incubated with crude extracts of liver or kidney, cysteine was produced. Whereas iodometric titrations indicated a complete cleavage with the purified enzyme, the Sullivan reaction indicated less than 40% cleavage.

Hydrolysis of conjugated 17-ketosteroids in urine concentrates by acetate buffers JOEL BITMAN (by invitation) and SAUL L COHEN *Dept of Physiological Chemistry, Univ of Minnesota Medical School, Minneapolis, Minn*. Butanol extracts of male urine prepared for studies on the hydrolysis of concentrates of the conjugated ketosteroids

showed a considerable loss (up to 45%) of these conjugates from the butanol extracts if the extraction was carried out at pH above 3.0. Similar losses occurred if the butanol concentrates were washed with buffers of pH above 3.0. This indicates the presence in urine of some conjugated ketosteroids whose salts are more soluble in water than in butanol. The BaCl_2 -acetate buffer hydrolytic technique of Talbot *et al* (1943) when applied to butanol extracts of normal male urine liberated 20–40% of the total ketosteroids, of which 40–60% was of the beta type. These amounts were independent of the pH of the urine existent when the butanol extracts were prepared. The same degree of hydrolysis occurred even when the BaCl_2 was omitted from the hydrolytic mixture and the butanol residues were heated with buffer alone. Hydrolysis with pH 5.8 acetate buffer was found to be 85% complete in 4 hours. No marked increase in the proportion of ketosteroids liberated by buffers occurred when the buffer pH was reduced until a pH of 3.0 or less was achieved. These results tend to indicate the presence in normal male urine of a specific group of conjugates whose salts are much more soluble in butanol than in water and which are sufficiently labile to be hydrolyzed by relatively mild conditions.

Influence of magnesium and cobalt on the inhibition of phosphatases by α -amino acids OSCAR BODANSKY *Memorial Hospital for The treatment of Cancer and Allied Diseases and the Sloan-Kettering Institute for Cancer Research, New York City*. In the presence of inhibiting concentrations of α -amino acids or cyanide the usual activating effect of magnesium on bone phosphatase was decreased and in some instances was transformed into a retardant effect. The extent of the activating effect of cobalt on bone phosphatase was decreased slightly as the concentration of amino acid was increased. In the conjoint presence of cobalt and magnesium, accomplished either before or after the start of the reaction, the degree of activation of bone phosphatase which had been inhibited by amino acids was much greater than with either cobalt or magnesium alone and counteracted to varying degrees the inhibition by amino acid. The activating effect of magnesium on intestinal phosphatase was unaffected as the concentration of amino acid was increased, the activating effect of cobalt was decreased. The extent of activation of intestinal phosphatase which had been inhibited by amino acids was about the same in the conjoint presence of cobalt and magnesium as in the presence of magnesium alone. Human osteogenic sarcoma phosphatase resembled normal rat bone phosphatase with respect to the extent of inhibitions by various amino acids and the influence of cobalt and magnesium on these inhibitions. The present findings are interpreted to indicate that α -amino acids inhibit bone, intestinal and osteo-

genic sarcoma phosphatases by combining with an essential metal component of these enzymes and that this component normally mediates the activation of bone and osteogenic sarcoma phosphatases, but not of intestinal phosphatase, by magnesium.

Quantitative separation and determination of small amounts of histidine and tyrosine employing paper chromatography DIANA BOLLING (by invitation), HERBERT A. SOBER (by invitation) and RICHARD J. BLOCK *Dept of Biochemistry and Physiology, New York Medical College, Flower and Fifth Ave Hospitals, New York City*. Pauly (1904) reported that histidine and tyrosine gave a red color when treated in alkaline solution with freshly diazotized sulfanilic acid. The use of this reaction for quantitative determinations has been limited by the difficulties in obtaining complete separation of these 2 amino acids. The excellent technique for the separation of amino acids by paper chromatography, introduced by Consden *et al* (*Biochem J* 36: 224, 1944), and the adaptation of this method for their estimation, based on the observation that the concentration of an amino acid on the paper was proportional to the area of the spot multiplied by the color density (Block, *Science* 108: 608, 1948), suggested that the Pauly reaction could be readily adapted to the determination of histidine, tyrosine, etc. Method: Histidine and tyrosine are separated by chromatography using a mixture of n-butanol, 100 parts, glacial acetic acid, 10 parts, saturated with water. Ascending chromatograms on S&S 598 or 596 paper are run for 3 hours. The paper is removed, dried, and sprayed with freshly diazotized sulfanilamide dissolved in n-butanol. The paper is allowed to air-dry for exactly 5 minutes. It is then sprayed with an emulsion of 5% sodium carbonate in 2 volumes of butanol. The chromatograph is air dried and the quantities of histidine and tyrosine are determined from the product of the color area times density. The results obtained on casein, zein and hemoglobin agree with the better values in the literature.

Influence of pituitary and adrenal glands on ketone body production by rat liver slices PHILIP K. BONDY (by invitation) and ALFRED E. WILHELM *Dept of Physiological Chemistry, Yale Medical School, New Haven, Conn*. Slices of rat liver were incubated in Krebs Ringer medium, with phosphate buffer, pH 7.4, in oxygen at 38°C. Ketone bodies were determined by the method of Greenberg and Lester on the total contents of the flask. All animals were fasted 18 hours before the experiment. Livers from normal rats produce $2.4 \pm 1.6 \mu\text{M}/100 \text{ mg}$ (dry weight) in 15 minutes, and $8.8 \pm 4.6 \mu\text{M}/100 \text{ mg}$ in 120 minutes, an increment of $3.5 \pm 4.3 \mu\text{M}/100 \text{ mg}/\text{hour}$. The rate of appearance of ketone bodies was constant from 5 minutes to 120 minutes. Livers from adrenalectomized rats formed $2.5 \pm 1.9 \mu\text{M}/100 \text{ mg}$ in 15 min-

utes, and $10.2 \pm 4.3 \mu\text{M}$ in 120 minutes, an increase of $4.4 \pm 2.9 \mu\text{M}/100 \text{ mg}/\text{hour}$. These results are not significantly different from the data obtained from normal rat livers. The livers of rats hypophysectomized several months previously produced $1.5 \pm 1.0 \mu\text{M}/100 \text{ mg}$ in 15 minutes, and $3.7 \pm 2.0 \mu\text{M}/100 \text{ mg}$ in 120 minutes, a rate of $1.3 \pm 2.0 \mu\text{M}/100 \text{ mg}/\text{hour}$. These values are significantly lower than those obtained with either normal or adrenalectomized animals. In normal rats, the body weight was found to be a significant factor, since liver slices from heavier rats produced more ketone bodies than did slices from lighter animals ($r = 0.8428$, p less than 0.05). This correlation was observed only in the 120-minute period. No such relationship between body weight and ketone body formation could be demonstrated for hypophysectomized or adrenalectomized animals.

A microbiological determination of D-phenylalanine ERNEST BOREK and HEINRICH WAELSCH *Depts. of Biochemistry, New York State Psychiatric Institute and Columbia Univ., New York City*. The microbiological determination of D-amino acids has been previously achieved by the use of two different varieties of microorganisms one of which utilizes only the L-amino acid, and the other, either the D or the D-L form. During studies of the metabolism of phenylalanine and its derivatives in *Lactobacillus Arabinosus* we found that, while these organisms can utilize only L-phenylalanine, they readily metabolize both optical antipodes of phenyllactic acid in lieu of the amino acid. Since the growth response of the microorganisms is nil to D-phenylalanine but complete to D-phenyllactic acid, and, since the chemical transformation of the amino acid to its hydroxy analogue is almost quantitative, a convenient determination of the D-amino acid is possible. Samples of D-L phenylalanine in microgram quantities, produce, after reaction with nitrous acid, almost twice the growth response of an identical, untreated aliquot. The blood of patients with oligophrenia phenylpyruvica has been subjected to a search for D-phenylalanine which has been claimed to accumulate in these subjects. Within the limits of error of the method the phenylalanine, which circulates in concentrations as high as 30 mg % the blood of these subjects is the L-isomer.

Incorporation of labeled lysine into the proteins of guinea pig liver homogenate HENRY BORSOOK, CLARA L. DEASY (by invitation), ARIE J. HAAGENS-MIT (by invitation), GEOFFREY KEIGHLEY (by invitation) and PETER H. LOWY (by invitation) *Kerckhoff Laboratories of Biology, California Institute of Technology, Pasadena, Calif.* The incorporation of L-lysine (labeled with C^{14} in the ϵ -position) into the proteins of guinea pig liver homogenate was studied using either the whole

homogenate or the sedimented fraction obtained by centrifuging the 15-fold diluted homogenate at 2500 g. Characteristics of the reaction with the whole homogenate are: its optimum pH is at 6.1, the presence of calcium is obligatory, the reaction proceeds as well in nitrogen as in oxygen, it is inhibited nearly completely by fluoride, and less completely by arsenate, arsenite, azide, cyanide and dinitrophenol, the concentration of L-lysine incorporated is approximately a linear function of the lysine concentration and is independent of the homogenate concentration. Characteristics of the reaction with the sedimented fraction are: its optimum pH is approximately 7.3, calcium accelerated the reaction only slightly and its presence is not obligatory, it proceeds under nitrogen but more slowly than under oxygen, it is inhibited slightly by fluoride and practically uninhibited by arsenate, arsenite, azide, or dinitrophenol, the concentration of lysine incorporated is a function of the total amount of lysine in the reaction mixture. The rate of incorporation of lysine into the proteins of the whole homogenate is approximately the same as that *in vivo*, the rate with the sedimented fraction is several times faster.

Passage of hemoglobin through the glomerular membranes and its excretion by the amphibian kidney PHYLLIS A. BOTT *Dept. of Physiological Chemistry, Woman's Medical College of Pennsylvania, Philadelphia, Penna.* Kidneys of amphibia were perfused with Ringer's solution containing human hemoglobin prepared by Drabkin's method (*J. Biol. Chem.* 164: 703, 1946). 'Direct' glomerular puncture experiments and 'indirect' (hemoglobin-inulin) experiments were made with methods similar to those used previously with other proteins (Bott and Richards, *J. Biol. Chem.* 141: 291, 1941). Indirect experiments. Hemoglobin excretion in ureteral urine was influenced by pH as in the experiments of Webster, Engel, Laug and Amberson (*J. Cell and Comp. Physiol.* 5: 399, 1934) with laked cells, and the percentage filtration calculated from these by the indirect method also seemed to be so influenced. In a number of cases the calculated percentage filtration of hemoglobin did not show an increase when the concentration of hemoglobin in the perfusion fluid was increased. Direct experiments. From glomerular collection analysis there appears to be considerable variation in the degree of completeness of hemoglobin filtration by the individual glomeruli, but possibly a trend toward more complete filtration with increasing concentration of hemoglobin in the perfusion fluid. Glomerular fluid and ureteral urine were collected simultaneously in a number of experiments.

Antithromboplastic activity of navy bean trypsin inhibitor *in vivo* DONALD E. BOWMAN *Dept. of Biochemistry and Pharmacology, Indiana Univ.*

School of Medicine, Indianapolis, Ind A highly active and abundant navy bean trypsin inhibitor has been used to retard the *in vivo* coagulation which results from the intravenous injection of trypsin in rabbits. This inhibitor was prepared by a modification of an earlier procedure employing isoelectric precipitation of inert proteins, fractional salting out of the active material and fractionation with alcohol. In rabbits the navy bean trypsin inhibitor confers a considerable degree of protection against the lethal effects of single large doses of intravenously injected trypsin or repeated small doses of the enzyme. Extensive pulmonary embolism which is almost invariably observed upon immediately examining rabbits killed with trypsin alone is not found upon sacrificing those receiving the enzyme plus its inhibitor. In rabbits receiving repeated small injections of trypsin the coagulation time of carotid blood is first observed to increase markedly and then gradually decrease, finally reaching a point considerably below the control level at the time of fatal termination. The initial rise is also observed with the enzyme plus its inhibitor, however, the subsequent fall is not as severe. Iodinated trypsin which retains relatively more of the proteolytic activity as compared with the hypotensive effect of the original enzyme also gives rise to pulmonary emboli particularly with repeated small doses. Single large doses have been less toxic than the untreated enzyme given in amounts sufficient to provide equivalent proteolytic capacity. Evidence of anaphylactic reactions was not observed upon intravenous injection of the inhibitor at 14-day intervals.

Tuberculostatic properties of autoclaved human plasma DONALD E. BOWMAN *Dept of Biochemistry and Pharmacology, Indiana Univ School of Medicine, Indianapolis, Ind* During an investigation of enzymatic factors in tuberculosis it has been observed that undiluted autoclaved human plasma containing glycerol is less able to support growth of the H37 strain of tubercle bacilli than is sterile plasma which has been coagulated at 80° for 10 min. On the latter surface growth of the organisms having typical staining properties can be observed in 2 to 4 days after inoculation while growth on plasma which has been autoclaved for 15 min at 15 lb pressure requires a week or more to reach a comparable point and subsequently shows much less growth. With non-autoclaved dog plasma or restored dessicated human plasma growth is comparable to that on autoclaved fresh human plasma. That the addition of a concentrate of the fluid derived from autoclaved human plasma to synthetic media consistently inhibits growth is readily observed and can be estimated by determining the nitrogen content of the washed organisms by the procedure described by Youmans.

Fluid derived from plasma coagulated at 80° does not inhibit growth. In fact in less favorable media such as that in which the yeast extract and surface active accelerating agents have been omitted from Dubos' synthetic media, fluid pressed from 80° coagulated plasma actually accelerates growth. Uric acid shows an inhibiting effect which it partially loses upon being autoclaved.

A biologically-active, reversible oxidation product of α -tocopherol PAUL D. BOYER *Div of Biochemistry, Univ of Minnesota, St Paul, Minn* A biologically-active oxidation product of α -tocopherol has been formed by reaction with two equivalents of Fe^{+++}/M and isolated as an unstable, colorless oil by extraction and chromatographic procedures. It has an absorption maximum at 237 $\text{m}\mu$ in isooctane ($\epsilon_M = 1.2 \times 10^4$), and is readily reduced to tocopherol by ascorbic acid or hydro-sulfite. The product is a structural isomer of α -tocopherylquinone, $\text{C}_{29}\text{H}_{50}\text{O}_3$, into which it is readily converted by a slight excess of Fe^{+++} and by acids and alkalis. Its antisterility activity is 1/10 parenterally and 1/30 orally of that of α -tocopherol. This suggests a relation of the oxidation product to the biochemical function of tocopherol. Tentatively the product is considered to be 2,5,7,8-tetramethyl-2-(4',8',12'-trimethyltridecyl)-6-keto-7-hydro-8,9-epoxychroman. The absence of an OH group is demonstrated by failure to react with reagents for OH groups and by the infra red absorption spectrum. The hetero ring is thus intact and the extra oxygen must be associated with the carbon ring in a cyclic or peroxide structure. The product liberates I_2 from NaI in Ac_2O , and this property, together with the ease of conversion to the quinone, has prevented direct reaction with carbonyl reagents. The ultraviolet absorption spectra and other properties of the molecule are best explained by an α - β unsaturated keto structure. Similar products from γ - and δ -tocopherols show maxima about 10 $\text{m}\mu$ shorter wave length, consonant with the postulated structure. Properties of the molecule and structural considerations suggest the location of the extra oxygen in a three-membered ring in the 8-9 position.

Evaluation of some lactic acid producing bacteria in the microbiological assay of amino acids MYRON BRIN (by invitation) and HAROLD H. WILLIAMS *Dept of Biochemistry and Nutrition and The School of Nutrition, Cornell Univ, Ithaca, N Y* The amino acid assay of complex feedstuffs containing relatively large amounts of lipids, complex carbohydrates, or both, offers difficulties not apparent in the assay of purified protein materials. This report deals with the comparative analysis of complex feeds by 5 bacteria previously proposed for amino acid assay. Whole egg, soybean oil meal, and clover hay were chosen as representative of

feedstuffs, and casein was included as a standard of comparison with literature values. Depending upon the amino acid requirements for the respective organisms, comparative assays for the essential amino acids were run on the above materials with *Lactobacillus arabinosus* 17-5, *Lactobacillus casei*, *Lactobacillus delbrueckii* LD5, *Leuconostoc mesenteroides* P-60, and *Streptococcus faecalis*. In order to measure differences of response between organisms to the test materials, a uniform basal medium was developed which is applicable to the 5 bacteria used. Comparative results indicate that all of the organisms do not yield equivalent amino acid values under similar conditions. It is concluded that under the conditions of this study 3 bacteria yielded the most accurate values, namely *Streptococcus faecalis*—arginine, histidine, lysine, methionine, threonine, tryptophan and valine, *Leuconostoc mesenteroides* P-60—histidine, lysine, methionine and phenylalanine, *Lactobacillus arabinosus* 17-5—leucine, leucine, and tryptophan.

Mechanism of histidine synthesis in lactic acid bacteria HARRY P. BROQUIST (by invitation) and ESMOND E. SNELL *Dept of Biochemistry, Univ of Wisconsin, Madison, Wis*. If *Lactobacillus arabinosus* 17-5 is cultured in a medium deficient in histidine and purine bases, the organism grows very slowly. Much more rapid growth is obtained on the addition of either histidine or individual purine bases. This suggests a relationship between histidine and purine bases in metabolism. The possibilities (reaction *a*) that histidine may serve as a precursor of purines, or (reaction *b*) that the purines may serve as a precursor of histidine are considered. Reaction *a* has been frequently proposed, and appears unlikely in view of present knowledge. Furthermore, the histidine requirement of *Streptococcus faecalis* R is not increased by culturing in the absence of the proposed product, purine bases. Data to be presented indicate rather that the purine bases serve as a precursor for the imidazole ring of histidine (reaction *b*) and that xanthine is particularly effective in this relationship. In the absence of vitamin B₆, histidine becomes essential for growth of *L. arabinosus* and cannot be replaced by purine bases, implying that vitamin B₆ is involved somewhere in reaction *b*. Imidazole pyruvic acid replaces histidine for both *L. arabinosus* and *S. faecalis*, but only when vitamin B₆ is present in the medium. Thus B₆ appears to function in conversion of this keto acid to the amino acid. If imidazole pyruvic acid is the immediate precursor of histidine this implies a wider significance for the transamination reaction than has recently been indicated.

Changes in sodium sulfate solutions in the upper and lower intestines of dogs GLADYS R. BUCHER (by invitation), CARL E. ANDERSON (by invita-

tion) and C. S. ROBINSON *Dept of Biochemistry, Vanderbilt University, Nashville, Tenn*. The ability of the small intestine to alter sodium sulfate has been studied in a double period test in a series of acute dog experiments using 2 methods of isolating the gut segments, and also in chronic dogs with Thury-Villa loops. In the acute experiments, segments were isolated using the terminal end of the Miller-Abbott apparatus in the jejunum and 60 cm from the ileocecal valve, or by mechanical obstruction with flat clamps in these regions. After a sulfate wash, each loop was filled with Na₂SO₄ (35–40 cc, 204 mEq/l) and drained for analysis after 20 minutes. Residual volume was obtained by determining the conductivity of an equal volume of 10% sucrose solution used as a rinse. Following a rinse with sulfate, a second 20-minute test was made. The analysis consisted of determining volume, pH, total base, ammonia, sulfate, chloride and total CO₂. The data from the 3 types of preparation were statistically homogenous. The first period samples in both upper and lower loops showed some significant differences from the second period samples. In upper loops, the second period samples were significantly different in possessing a more acid pH, higher sulfate and a lower chloride concentration. In the lower loops, the second period samples were significantly different in possessing a more acid pH, increase in total base concentration and a decrease in the concentration of ammonia. These ionic shifts occurred when no consistent differences in volume were detected. The sample differences bespeak a reduction in the rate of ionic shifts in the second period, due possibly to a fatigue or saturation phenomenon.

Anaerobic and aerobic glycolysis of parasitic tissue helminths ERNEST BUEDEL *Dept of Pharmacology, School of Medicine, Western Reserve Univ, Cleveland, Ohio*. In contrast to tissues from vertebrates and to many bacteria, lactic acid is not the major end product of the anaerobic carbohydrate metabolism of parasitic helminths living in the intestinal tract or the bile ducts. However, lactic acid production accounted for at least 80% of the total amount of carbohydrate utilized anaerobically by 2 tissue parasites, the filarial nematode, *Litomosoides carinii*, and the trematode, *Schistosoma mansoni*. This was established by isolation and identification of the benzimidazole and the p-bromphenacyl derivatives from media in which the parasites had been incubated in the presence of glucose. Glycolysis of *Litomosoides carinii* was greatly reduced by aerobiosis and inhibition of its respiration resulted in a compensatory increase of glycolysis. In schistosomes and in another tissue parasite, the filarial nematode, *Dracunculus insignis*, the rates of glucose utilization and of lactic acid production remained

constant under anaerobic and aerobic (1-100% oxygen) conditions, and were not affected by inhibitors of respiration. Evidence will be discussed indicating that a large amount of energy derived from oxidative reactions is essential for survival of *Leishmaniasis carinii*, but not for that of schistosomes, in which respiration and glycolysis occur independently of each other. Glycolysis of the parasites was reduced markedly by low concentrations of -SH inhibitors. This effect could not be reversed by glutathione, dithiothreitol or H₂S. Dithiothreitol (but not glutathione) greatly enhanced the inhibitory action of p-chloromercuric benzoate on glycolysis of the schistosomes.

Bacterial glucuronidase HENRY J. BUEHLER (by invitation), PHILIP A. KATZMAN and EDWARD A. DOIST, *Laboratory of Biological Chemistry, Saint Louis Univ. School of Medicine, Saint Louis, Mo.* The estimation of several important substances excreted in the urine as glucuronides depends upon an initial hydrolysis. Since the prevailing methods for hydrolyzing such substances result in considerable destruction, we have directed our efforts toward the preparation of potent glucuronidase extracts of bacterial origin. Of fourteen organisms grown in a 1% peptone medium only *C. rosea*, *C. hoffmanni* and *E. coli* produced glucuronidase as indicated by the hydrolysis of phenolphthalein glucuronide. *E. coli* was selected for further study because it showed the greatest glucuronidase production under these conditions. The optimum pH for enzyme production by this organism at 25°C in a peptone-beef extract medium containing 0.05M phosphate buffer was found to be about 7.3. The optimum pH for enzyme activity using phenolphthalein glucuronide as the substrate and 0.033M KH₂PO₄ as buffer was determined to be approximately 6.2. The production of glucuronidase by *E. coli* can be markedly increased by the addition of menthol glucuronide to the growth medium. The addition of 0.5% menthol glucuronide in this manner has effected as high as a 70-fold increase in the yield of the enzyme. Employing as the enzyme preparation the culture fluid after dialysis and filtration, phenolphthalein glucuronide was quantitatively hydrolyzed in 2 hours. The extent of hydrolysis for shorter periods was not measured.

L-Alanine oxidase of rabbit kidney and liver M. V. BUELL and J. L. STILL (introduced by D. E. GREEN), *Institute for Enzyme Research, Univ. of Wisconsin, Madison, Wis.* Liver and kidney cytochrome preparations can catalyze the complete oxidation of L-alanine to CO₂, NH₃ and H₂O. This process requires the presence of some member of the citric acid cycle in sparking concentration. It appears that the first step in the complete oxidation is a transamination between alanine and α-ketoglutarate with formation of pyruvate and

glutamate. Once the process is properly started the oxidation of pyruvate and glutamate both of which pass through α-ketoglutarate as an intermediary step provide a continuous supply of α-ketoglutarate for the initial transamination reaction. The alanine-glutamic transaminase is capable of working at catalytic concentrations of α-ketoglutarate. Under appropriate conditions the cytochrome system can synthesize L-alanine from pyruvic acid and NH₃. This synthesis involves both the synthesis of glutamate from α-ketoglutarate and NH₃ and the reversal of the transamination reaction. $2 \alpha\text{-ketoglutarate} + \text{NH}_3 \rightarrow \text{glutamate} + \text{succinate}$ $\text{glutamate} + \text{pyruvate} \rightarrow \alpha\text{-ketoglutarate} + \text{alanine}$. The synthesis of glutamate from α-ketoglutarate and NH₃ proceeds very rapidly under aerobic conditions. α-Ketoglutarate in excess suppresses almost completely ammonia production from either glutamate or alanine in accordance with the dictates of the above equations.

Effect of amino acid administration on amino acid oxidase activity R. N. CAGAN (by invitation), J. L. GRAY (by invitation) and H. JENSEN, *Medical Dept. Field Research Laboratory, Fort Knox, Ky.* The effect of intraperitoneal injection of an amino acid mixture on the amino acid oxidase activity of the liver and kidney was studied in normal, hypophysectomized, adrenalectomized and thyroidectomized rats. The enzyme activity of a buffered extract of homogenized tissue was measured. Simultaneous determinations of blood amino acids, urea and glucose were made. An increase in the amino acid oxidase activity of the liver of normal animals was found after amino acid administration while no such increase was observed in the operated animals. The amino acid oxidase activity of the kidney was found to be dependent principally upon the amino acid level of the blood and not upon hormonal control. Comparison of the amino acid oxidase activity of normal and operated animals was made.

Direct utilization of sucrose by *Leuconostoc* WARNER W. CARLSON and VIRGINIA WHITESIDE CARLSON (introduced by EMMETT B. CARMICHAEL), *Biochemistry Dept., Medical College of Alabama, Birmingham, Ala.* Several instances of direct utilization of disaccharides by microorganisms have been reported in the literature. With the disaccharide as the carbohydrate source, earlier growth and acid production were observed than resulted from the use in the media of the constituent monosaccharides. In the case of *Leuconostoc mesenteroides* and *L. dextranicum* direct utilization of sucrose has been indicated as a result of the fact that these organisms synthesize dextran only from the intact disaccharide, no polysaccharide being formed when glucose, fructose, or a mixture of the monosaccharides are employed. We have

observed earlier growth and more rapid acid production from sucrose by various strains of *Leuconostoc* regardless of whether a particular strain formed large amounts or only a trace of the polysaccharide. Investigation of the growth requirement of certain strains of *Leuconostoc* in a chemically defined sucrose medium, and in media containing the constituent monosaccharides revealed several differences, the most important of which was an apparent absence of a biotin requirement when the disaccharide was employed, as compared with a need for this vitamin when glucose or fructose were employed. Since sucrose often is known to contain significant amounts of biotin, the studies were also made with media containing different amounts of raw egg white.

Toxicity studies with demerol hydrochloride (isonipECAINE) on adult male guinea pigs EM-METT B. CARMICHAEL, WALTER H. JOHNSON (by invitation) and FRANK A. KAY (by invitation) *Biochemistry Dept., Medical College of Alabama, Birmingham, Ala.* Toxicity studies have been made with Demerol hydrochloride on adult male guinea pigs. A fresh aqueous solution was injected intraperitoneally. The doses varied by 10 mg increments from 80 to 170 mg/kg. The smallest dose to cause death was 110 mg/kg while a dose of 170 mg/kg killed 100% of the animals. With the large doses, animals usually became nervous and excitable within 5 to 10 minutes and as the symptoms became more severe, convulsions developed. Then an animal would fall on its side during a convulsion and if the dose was lethal, the animal usually would not stand up before expiring. The survival time for those animals that died varied from 12 to 323 minutes with a majority of the animals dying in less than 2 hours. The LD₅₀ of Demerol for adult male guinea pigs seems to be in the range 130 to 150 mg/kg.

Separation of three naturally occurring adenine ribonucleotides by paper chromatography and ion-exchange C. E. CARTER (by invitation) and WALDO E. COHN *Biology Division, Oak Ridge National Laboratory, Oak Ridge, Tenn.* Adenylic acid prepared from yeast nucleic acid was assigned the structure of adenosine-3-phosphoric acid by Levene. It has been found by techniques of paper chromatography that yeast adenylic acid may be resolved into two components and by an anion exchange procedure these two components may be separated from each other and from muscle adenylic acid. The two adenylic acids in yeast nucleic acid are degraded to adenine by acid hydrolysis and to adenosine by weak alkaline hydrolysis and kidney nucleotidase. Neither component is desaminated by Schmidt's muscle adenylic acid desaminase and the phosphorous of both is acid labile. These findings suggest that nucleic acid contains adenosine-2-phosphoric acid and adenosine-3-

phosphoric acid (the 1 and 4 positions on the ribose carbon chain being excluded by the furanose ring and the 5 position by the acid labile nature of the phosphorous of yeast adenylic acid) although other possibilities for isomerism are not excluded. The ion-exchange separation of adenylic acids was achieved by elution with dilute formic, acetic or hydrochloric acid solutions from strong-base anion exchangers. Separation of nucleotides by paper chromatography was obtained in a two phase system consisting of isoamyl alcohol and 5% Na₂HPO₄ in water.

Inositol lipids of soybean HERBERT E. CARTER, WALTER D. CELMER (by invitation), MACK H. McCORMICK (by invitation), CLIFFORD O. NYMAN (by invitation) and FRANCES W. SAUNDERS (by invitation) *Div. of Biochemistry, Noyes Laboratory of Chemistry, Urbana, Ill.* Attempts to prepare inositol lipid from soybean by the procedure of Woolley (*J. Biol. Chem.*, 147: 581, 1943) yielded non-homogeneous products containing a non-reducing carbohydrate which gave positive Selivanoff and diazouracil tests. Therefore, other fractionation procedures were studied, using crude-soybean phosphatide from several commercial sources. The crude material was freed of oil and the product (3-4% inositol) was extracted with glacial acetic acid. The residue was a crude inositol lipid (10-13% inositol) which contained about 80% of the original inositol. Addition of hexane to the glacial acetic acid extract gave a white precipitate (2-5% inositol) containing a large amount of the non-reducing carbohydrate. This material when freed of inositol gave a positive test for galactose and sucrose. The optical rotation and the properties of the acetyl derivative were similar to those of raffinose. The acetic acid insoluble fraction was further purified by distribution between aqueous acetic acid and cyclohexane giving a white powder containing 11-14% of inositol (Selivanoff test negative). Distribution of this material between hexane and methanol gave two inositol-containing fractions.

Variability in the Beckman spectrophotometer W. O. CASTER (by invitation) and OLAF MICKELSEN *Nutrition Section, U. S. Public Health Service, Bethesda, Md.* Different Beckman Spectrophotometers may yield E_{1%¹cm} values differing by as much as 1-5% (Ewing and Parsons, *Anal. Chem.* 20: 423, 1948). One instrument was subjected to a series of control studies in order to determine the cause of this variation. Analysis of variance revealed several distinct and statistically significant sources of variability. Under constant conditions duplicate readings can be repeated within $\sigma = 0.2\%$. This is only slightly above the error in reading the instrument scale. This has often been considered the 'true error' of this instrument. Quartz cell correction factors, (i.e. to compensate

for the lack of agreement between readings obtained from different cells when all are filled with identical solutions) change with changes in wave length (and simultaneous changes in slit width) to give an additional variation of 0.2%. From the circuit the phototube appeared to be by far the greatest source of inconsistency. The variation between a series of ultraviolet-sensitive phototubes was $\sigma = 1.1\%$ and between red-sensitive and ultraviolet-sensitive phototubes in their overlapping range, 600–625 $m\mu$, was $\sigma = 3.2\%$. Changes in slit width over an 0.08 mm range resulted in a 0.9% variation in $E_{1\text{cm}}^{1\%}$ values. Changes in wave length over a 23 $m\mu$ range likewise resulted in a 0.5% variation. Together these error factors are considerably greater than the 0.2% so often reported as the variability of this instrument. In the exact interpretation of $E_{1\text{cm}}^{1\%}$ values these factors should be considered.

Fractionation and chemical studies of proteins of rat liver. ALFRED CHAUTIN, E. C. GJESSING and STEPHAN LUDEWIG, *Biochemical Laboratory, Univ. of Virginia, Charlottesville, Va.* The proteins of saline extracts of rat liver have been fractionated by isoelectric precipitation and ethanol. A relatively large fraction containing a protein-lipide-nucleic acid complex was separated by isoelectric precipitation. A series of proteins were obtained by adjusting the ethanol and hydrogen-ion concentrations. These fractions were analyzed for their nitrogen, lipid and nucleic acid contents. Data for the distribution of arginase, phosphatase, catalase, esterase, succinic dehydrogenase and fluorophosphatase in these fractions will be presented.

Concentration of amino acids by the rat diaphragm suspended in artificial media. HALVOR N. CHRISTENSEN, *Children's Hospital and Dept. of Biological Chemistry, Harvard Medical School, Boston, Mass.* A study has been made of the activity of excised rat diaphragm in maintaining cellular amino acids at much higher concentrations than those of the extracellular fluid. Two procedures were used. 1) One hemidiaphragm was analyzed immediately, the other after shaking in a given medium. The amino acid concentration of each was referred to the appropriate extracellular fluid. 2) The two hemidiaphragms were shaken simultaneously in media identical except for one component. A solution containing 103 mM NaCl, 25 mM NaHCO_3 , 2.5 mM CaCl_2 and 20 mM sodium pyruvate in an O_2 - CO_2 atmosphere maintained the concentrating activity for glycine unchanged for 3 hours. α -Ketoglutarate served in place of pyruvate. When supplemented with pyruvate, rat plasma was equally satisfactory. The diaphragm glycine was responsive to the fluid glycine, falling at one fluid level and rising at a slightly higher one. In the absence of oxygen, or the presence of cyanide, arsenite, 80 mM potassium, or 2,4-dinitro-

phenol at 10^{-3} to 5×10^{-6} M, glycine was rapidly lost from the diaphragm. Pyruvate and dinitrophenol added to rat plasma stimulated and inhibited respectively the concentration of α -amino acids (measured collectively by ninhydrin). These observations relate to the energy source for amino acid concentration. All α -amino acids added to the medium at 21 mM concentration diminished by about $\frac{1}{3}$ the glycine retained by the suspended diaphragm. Only α -amino acids had this effect, and pairs of optical antipodes were equally inhibitory. This inhibition, earlier shown in the intact animal, is interpreted as a competitive phenomenon.

Nitrogenous metabolism of the earthworm (*Lumbricus terrestris*). STANLEY COHEN (by invitation) and HOWARD B. LEWIS, *Dept. of Biological Chemistry, Medical School, Univ. of Michigan, Ann Arbor, Mich.* In the normal earthworm, the chief nitrogenous component of the excreta was ammonia (66–91%), with traces only of urea (<10%). During inanition, the urea content was greatly increased so that urea was the most important nitrogenous constituent of the excreta. Thus, after 18 days' fasting, from 82 to 86% of the nitrogen was present as urea and less than 10% as ammonia. When arginine was fed by tube to normal earthworms, the excretion of urea was greatly increased. Small increases in the amount of urea excreted were noted after the oral administration of citrulline, but not after ingestion of ornithine, glutamic acid, glutamine, glycine, alanine, histidine, or ammonium chloride. When citrulline was fed simultaneously with glycine, alanine, or glutamic acid, the urea excretion exceeded that observed when citrulline or the other amino acids were fed alone. The administration of ornithine with other amino acids did not alter the excretion of urea.

Detection of 7-keto-cholesterol in blood plasma. H. B. COLLIER and R. H. COX (by invitation), *Dept. of Biochemistry and College of Pharmacy, University of Saskatchewan, Saskatoon, Sask., Canada.* In connection with the administration of pure 7-keto-cholesterol to rabbits a method was sought for its detection in plasma filtrates. The Liebermann-Burchard reaction is negative, but with the Tschugaeff reagent (Trappe, *Z. Physiol. Chem.* 273:177, 1942) the compound gives an intense yellow color with an absorption maximum at 432 $m\mu$ (Coleman model 11 spectrophotometer) and a green fluorescence. Cholesterol gives a pink color, with absorption maximum at 503 $m\mu$, and a yellowish fluorescence. (A similar color, with maxima at 515–520 $m\mu$, is also given by cholestadiene (3,4,5,6), coprostene-(4,5)-one-3, and dicholesteryl ether.) When the reaction is applied to dried acetone-alcohol filtrates of plasma, 7-keto-cholesterol may be detected by a peak in the spectrophotometric absorption curve at 432 $m\mu$. However, with mixtures of cholesterol and 7-keto-cholesterol, nei-

then the optical densities in the visible spectrum nor the fluorescence intensities are additive. Semi-quantitative separation and estimation of cholesterol and 7-keto-cholesterol may be achieved by adsorption on alumina from petroleum ether, elution of cholesterol by chloroform and of 7-keto-cholesterol by acetone, followed by color development.

Demonstration of TPN dehydrogenases in the tissues of higher plants ERIC E. CONN (by invitation), BIRGIT VENNESLAND and E. A. EVANS, JR. *Dept. of Biochemistry, Univ. of Chicago, Chicago, Ill.* Ammonium sulfate fractions of seven different higher plants which contain oxaloacetic carboxylase activated by manganous ions have been shown to contain a malic dehydrogenase requiring triphosphopyridine nucleotide (TPN) as a coenzyme. The overall reaction catalyzed by these preparations may be written

malate + TPN_{oxidized} \rightleftharpoons

pyruvate + CO₂ + TPN_{reduced}

and is analogous to the reaction catalyzed by the 'malic enzyme' of pigeon liver as described by Ochoa. The main difficulty in demonstrating the occurrence of the reaction in plant preparations is associated with the widespread distribution of enzymes which destroy TPN. This destruction can be prevented by muscle adenylic acid, adenosine triphosphate, diphosphopyridine nucleotide, and to a lesser extent, yeast adenylic acid, but not by nicotinamide or adenosine. The destruction of reduced TPN is accompanied by the disappearance of the absorption band at 340 mμ and therefore simulates a reoxidation of the nucleotide. The practical significance of these facts in connection with the procedures used to demonstrate the reaction will be discussed. A detailed study of the dehydrogenase from wheat germ has been made. Observations with parsley root, parsnips, beets, carrots, spinach and peas indicate a general similarity in the properties of the dehydrogenases and of the factors which destroy TPN in crude protein preparations from all these different plant sources.

Formation of acetoacetic acid from radioactive leucine MINOR J. COON (by invitation), SAMUEL GURIN and D. WRIGHT WILSON. *Dept. of Physiological Chemistry, School of Medicine, Univ. of Pennsylvania, Philadelphia, Penna.* A fasted phlorhizinized rat was injected subcutaneously with a solution of 100 mg. of DL-leucine labeled in the β position with C¹⁴. The acetoacetate which appeared in the urine was degraded by standard procedures. The acetone fraction was found to be radioactive, and iodoform prepared from it accounted for all of the isotope present. These findings are in accord with the view that the carboxyl group of leucine is lost early in the course of metabolism. In other experiments, the radioactive amino acid was incubated with rat liver slices. The aceto-

acetate formed was oxidized with permanganate to produce formic and acetic acids, both of which proved to be radioactive. It was calculated that the methyl and methylene carbons of the acetoacetate had approximately the same concentration of isotope. Accordingly, at some stage in the metabolism of leucine, its α and β carbons must split off as a two-carbon intermediate which is capable of condensing to form acetoacetate.

Effects of feeding an ethanolamine analogue (diethanolamine) on the formation of liver phospholipides W. E. CORNATZER (by invitation), CAMILLO ARTOM and MARIETTA CROWDER (by invitation). *Dept. of Biochemistry, Bowman Gray School of Medicine, Winston-Salem, N. C.* With the aid of radioactive P as an indicator it was previously shown that the administration of a single large dose of diethanolamine to rats on low protein diets stimulates the lipid phosphorylation in the liver to a degree similar to, or greater than that observed after ethanolamine was given under the same conditions. With either substance, the stimulation involves both lecithin and cephalin fractions. The results are quite different when diethanolamine is added to the diets and fed over a period of 7 to 12 days. Under this condition the rate of lipid phosphorylation in the liver becomes markedly lower than in the controls on the same diets, unsupplemented or supplemented with ethanolamine. The decrease is mainly due to a diminished rate of formation of lecithins. Changes in the amount and distribution of liver phospholipides (increases in the total and non-choline containing phospholipides with a considerable decrease in the ratio lecithins to total phospholipides) were also noted. Indirect evidence was obtained for the presence of diethanolamine in the liver phospholipides of rats on diets supplemented with this compound. It is suggested that in these animals considerable amounts of diethanolamine-containing phospholipides are formed, and that these atypical phospholipides, being less easily metabolized than the natural cephalins, accumulate in the liver. This effect, in turn, would lead to a marked decrease in the formation of lecithins through a mechanism which remains obscure.

Electrophoretic patterns of plasma proteins during pregnancy and following delivery MARGARET N. CORYEIL (by invitation), ELIOT F. BEACH, and ABNER ROBINSON (by invitation). *Research Laboratory, Children's Fund of Michigan, Detroit, Mich.* The changes which occur in the plasma proteins of women at various intervals in pregnancy and postpartum are demonstrated by data obtained by use of the Tiselius electrophoresis technique with 89 plasma samples from the blood of 11 non-pregnant women, 23 women during pregnancy and postpartum, and the cords of 12 infants. Determinations were made with 3, 7, and 17 samples ob-

tained during the first, second, and third trimesters of pregnancy respectively, 16 maternal samples obtained at delivery, 10 samples within 5 days, and 13 samples 5 or more weeks postpartum. The data reveal a smooth progression of changes in all plasma protein fractions during the 3 trimesters of pregnancy. Comparison of the averages for non-pregnant patterns and those at delivery shows decreases in the absolute levels of gamma globulin of from 28 to 35%, respectively, while α_1 , α_2 , and beta globulins, and fibrinogen, increased 29, 41, 36, and 29%, respectively. During the 5 days following delivery there was some further fall in albumin and gamma globulins and a rise in α_1 globulin. By 5 to 9-weeks postpartum all subjects had plasma protein patterns similar to those of non-pregnant women, with complete restoration of the albumin fraction although gamma globulin was still reduced and α_1 and beta globulins were slightly elevated. Effects of factors such as milk flow, lactation failure, or renewed menstruation, upon the plasma protein patterns were not apparent.

Oral ingestion of histidine and the glutamic acid blood level in rats. H. R. CROOKSHANK and BERNARD F. CLOWDUS (introduced by EMMETT B. CARMICHAEL) *Biochemistry Dept., Medical College of Alabama, Birmingham, Ala.* The course of histidine metabolism and the conversion of histidine to glutamic acid was studied in previously fasted rats by assaying the blood for histidine, total imidazoles, glutamic acid, and amino nitrogen both before and at intervals after feeding single doses of L-Histidine. The histidine, total imidazoles, and amino nitrogen reached maximal concentrations in 1 hour after feeding and returned to the fasting level in 6 to 10 hours. No significant change in the glutamic acid level was observed, either before or at any interval after ingestion of L-Histidine. The data seem to indicate either little conversion of histidine to glutamic acid or that the glutamic acid thus formed is produced too slowly to be detected by our method or is converted to another metabolite which retains the alpha-amino nitrogen.

Incorporation of P^{32} during the operation of the cyclophorase system. R. CROSS, W. ATCHLEY and H. ALBAUM (introduced by D. E. GREEN) *Enzyme Laboratory, College of Physicians and Surgeons, Columbia University, New York City.* When the cyclophorase system is allowed to carry out the oxidation of any member of the citric acid cycle, of proline, glutamate and β -hydroxybutyrate in presence of radioactive inorganic phosphate it is found that the enzyme gel after thorough washing with 0.9% KCl is radioactive and the radioactivity is from 5-10 times as high as that of the blank treated in the same way except without added substrate. Under optimum conditions the radioactivity μ mol of total phosphate extractable from the gel by treatment with 5% trichloroacetic acid

approaches the value for the radioactivity/ μ mol of inorganic phosphate in the original digest. Arsenite and capryl alcohol abolish this incorporation of radioactive phosphate. Gramicidin and dinitrophenol only partially inhibit the incorporation though both together reduce the level of radioactivity to the level of the blank without substrate. Analysis of the radioactive gel has shown that either inorganic phosphate or one or more substances which estimate as inorganic phosphate are largely responsible for the radioactivity. The fraction corresponding to the adenosine pyrophosphate is also highly radioactive and it has been shown by enzymatic procedures that the radioactivity actually resided in the pyrophosphate moieties of ATP and ADP. Incorporation of P^{32} accompanies the oxidation of succinic acid in the cyclophorase system but not oxidation in the classical succinic oxidase system.

Influences of dietary protein transmittal of growth factor. FRANK A. CSONKA and M. W. OLSEN (by invitation) *Bureau of Human Nutrition and Home Economics and Bureau of Animal Industry, Agricultural Research Admin., U. S. D. A., Washington, D. C.* Evidence has been presented previously that the cystine and methionine content of a hen's egg may be increased by feeding a high-protein casein diet (Csonka, Denton, and Ringel, *J. Biol. Chem.*, 169: 259, 1947). In the present work, two pens of chickens were used to furnish eggs for incubation, one group was fed a high-protein diet of which 20% was casein and the other group was fed a low-protein diet containing no casein. Eggs were incubated from both pens at the same time and the chicks were reared together to 4 weeks of age on the same growing mash ration which had no casein. The chicks from the hens fed the casein diet grew faster than those from the hens fed the low protein diet, as shown by their greater body weight at 4 weeks of age. This difference in chick growth is related to the maternal dietary protein as the chief variable component in our experimental arrangement, the growth effect being transmitted through the egg to the chick. When the casein was replaced in the hen's ration with an equivalent quantity of soybean meal, the same accelerated growth effect was not observed. Addition of dried cow manure or Wilson's liver fraction 'L' to the chick mash inhibited the growth of the chicks that originated from the hens fed the high protein casein ration. The same supplements, however, slightly accelerated the growth of the chicks that had descended from parents fed the low protein ration. The growth of the chicks on the supplemented diet whose parents received a high protein soybean ration was not affected.

An ultraviolet spectrophotometric method for the determination of benzene hexachloride. BERNARD DAVIDOW and GEOFFREY WOODARD (introduced by R. L. GRANT) *Div. of Pharmacology, Food and*

Drug Administration, Federal Security Agency, Washington 25, D C A method has been developed for the estimation of small quantities of benzene hexachloride. It is based upon the conversion of the benzene hexachloride to 1,2,4-, 1,2,3- and 1,3,5-trichlorobenzene by alkaline hydrolysis. Of the mixture of trichlorobenzenes formed approximately 82% is the 1,2,4-trichlorobenzene which has a characteristic spectral absorption curve in the ultraviolet region. Advantage was taken of these facts in developing a quantitative method. The method consists of the initial extraction of the benzene hexachloride with ether from the material to be examined, and the conversion of the benzene hexachloride to the 1,2,4-trichlorobenzene by refluxing with 1N methanolic potassium hydroxide for one hour. Purification of the trichlorobenzene is accomplished by extracting with hexane and washing with water, and when necessary by the use of magnesium oxide or alumina chromatographic columns. The quantity of the trichlorobenzene is estimated by measurement of its optical density at $286\text{ }\mu$. Spectral absorption due to other substances is eliminated by applying a formula for the resolution of a two component color system. In this manner as little as $100\text{ }\mu\text{g}$ /total sample may be determined in biological tissues, in spray residues on spinach and cabbage, and in animal laboratory diets.

Isolation of biochemically deficient mutants of bacteria by means of penicillin BERNARD D. DAVIS, U S P H S, *Tuberculosis Research Laboratory, Cornell Univ. Medical College, New York City*. Mutants with increased nutritional requirements have been difficult to isolate efficiently because any medium enriched to permit growth of the mutants will also foster growth of non-mutant organisms. A method of selectively isolating such mutants from large populations suggested itself on the basis of the reports that penicillin sterilizes bacteria only under conditions which permit growth. Mutants were therefore exposed to penicillin in minimal medium in which they were unable to grow, and were found to survive while the predominant non-mutant population was eliminated. This screening technique proved to be very efficient when applied to ultraviolet irradiated *E. coli*, and made it possible in a short time to isolate mutants with individual requirements for almost all the vitamins and naturally occurring amino acids, and less specific requirements for purines or pyrimidines, as well as requirements for unknown factors in yeast extract. By testing the syntrophic effect of certain mutants on others grown adjacent to them on solid media, it has been possible to demonstrate several instances in which mutants with a common requirement are blocked at different stages in the synthesis of the nutritive (arginine, proline, histidine, phenylalanine plus tyrosine, thiamine).

Those mutants which visibly feed others must secrete into the medium considerable amounts of a stable compound which is used in biosynthesis.

Peptides: metabolic and structural intermediates in protein metabolism CLARA L. DEASY (by invitation), HENRY BORSOOK, ARIE J. HAAGEN-SMIT (by invitation), GEOFFREY KEIGHLEY (by invitation), and PETER H. LOWY (by invitation) *Kerckhoff Laboratories of Biology, California Institute of Technology, Pasadena, Calif.* A large peptide (designated Peptide A) was isolated by starch chromatography from the liver of albacore, beef, guinea pig, hog, horse, lamb and rat and from Witte's peptone. The peptide isolated from different sources had (within the limits of analytical accuracy) the same amino acid composition. The following amino acids have been demonstrated in it: alanine, arginine, aspartic acid, glutamic acid, glycine, histidine, isoleucine, leucine, lysine, methionine, proline, serine, threonine, tryptophan and tyrosine. Guinea pig liver was found to contain a number of other peptides. After incubating the liver homogenate with C^{14} -labeled glycine, leucine or lysine the labeled amino acids were extensively incorporated into Peptide A. In addition leucine is rapidly incorporated into one other peptide and more slowly into another. Labeled glycine (or an amino acid derived from it) was rapidly incorporated into two other peptides. The peptides into which labeled glycine, leucine and lysine are incorporated are normally present in guinea pig liver. They and free amino acids increase during incubation of liver homogenate, more at pH 6.0-6.5 than at 7.0-7.5. The incorporation of glycine and leucine is much faster into the peptides than into the proteins. This fact and the finding of the same peptide (Peptide A) in liver and as a major product of the peptic digestion of fibrin (Witte's peptone), are evidence that peptides are metabolic as well as structural intermediates in protein metabolism.

Studies of nuclei isolated from normal rat and rabbit liver by a modified Behrens technique ALEXANDER L. DOUNCE, GARSON H. TISHKOFF (by invitation), SHIRLEY R. BARNETT (by invitation), and RICHARD M. FREER (by invitation) *Dept. of Pathology and Biochemistry, School of Medicine and Dentistry, Univ. of Rochester, Rochester, N. Y.* Nuclei were prepared from normal rat and rabbit liver by a modification of the method of Behrens in order to avoid the use of aqueous solvents. The desoxyribonucleic acid of the Behrens nuclei was difficultly extractable, and was at least 50% lower in concentration than the desoxyribonucleic acid of nuclei prepared by aqueous solvents at pH 6.0. This finding apparently is due to the loss of much material other than nucleic acid from the latter type of nuclei during their preparation. Arginase, aldolase, catalase, cytochrome oxidase, esterase,

and lipase were present in the isolated nuclei. Precise quantitative measurements of the enzyme activity of Behrens type nuclei are difficult to carry out because of agglutination of the nuclei near pH 7.0. Free amino acids were extracted from the nuclei with 76% alcohol and were studied by the method of paper chromatography. The pattern yielded by the nuclei appears to be identical with that yielded by the whole tissue. The spots of maximal intensity are those due to glutamic acid, glycine, alanine, leucine plus isoleucine, β -alanine, and probably glutamine, and also to a spot thought to be due to taurine. Aspartic acid, serine, and valine are present in easily detectable but lower amounts, while most of the essential amino acids were detectable only in trace amounts. Glutathione was uniformly detected in nuclei. Its chromatographic detection in whole tissue was more difficult, perhaps because of greater instability in cytoplasm. Glutathione was found to be about equal in concentration in nuclei and whole tissue by chemical titration with iodate.

Hormonal influences on cytochrome c metabolism and liver regeneration. DAVID L. DRABKIN, *Dept. of Physiological Chemistry, Graduate School of Medicine, Univ. of Pennsylvania, Philadelphia, Penna.* Thyrotoxicosis, induced by thyroxine administration to rats, increased the concentration and content of cytochrome c in their tissues (Drabkin, D. L., *Federation Proc.*, 7: 151, 483, 1948). In a continuation of these studies it has been found that, despite the higher concentration of liver cytochrome c and PNA in such thyroxinized animals, instead of the usual increase in cytochrome c and PNA observed in liver regenerating after partial hepatectomy, there occurred a reduction in the concentration of these constituents, accompanied by an appreciably reduced liver regeneration (43.9% in the thyrotoxic as against 73.9% in the normal). After bilateral adrenalectomy, performed at the time of liver lobectomy in rats on a high (31%) protein diet, liver regeneration in 14 days was consistently greater than that of normal controls and of thyroidectomized animals (89.7% in adrenalectomized, 73.9% in normal, and 65.2% in thyroidectomized). Excluding liver tissue, completely adrenalectomized rats, like thyroidectomized animals, had significant decreases in the cytochrome c concentration and content of heart, kidney and skeletal muscle.

Electrophoretic comparison of plasma and body fluid proteins in certain diseases. ROBERT L. DRYER (by invitation), JACQUELINE H. BUDDE (by invitation), W. D. PAUL (by invitation), and JOSEPH I. ROUTH, *Depts. of Biochemistry and Medicine, College of Medicine, State Univ. of Iowa, Iowa City, Iowa.* We have compared the protein components of plasma and body fluids from patients with a variety of clinically diagnosed illnesses. Blood

samples were withdrawn whenever it was necessary to perform thoracentesis, paracentesis, or joint aspiration. Protein components of the corresponding samples were determined by electrophoresis in a single center section cell. Samples were withdrawn from a number of the subjects at intervals over a considerable period of time. Ten patients with various cardiovascular diseases were studied, and in general it was found that the paracentesis and thoracentesis fluids showed a distribution of protein components which closely paralleled that of the plasma. Both the plasma and the fluid showed a marked drop in albumin with a corresponding increase in globulins, especially γ -globulin. A urine sample from one subject with marked decompensation gave a protein distribution which almost exactly matched the plasma. Eleven patients with neoplastic conditions ranging from gastric carcinoma to reticuloendothelial hyperplasia were also studied. Again the most outstanding characteristic was the marked reduction in albumin. In a case of multiple myeloma a component migrating faster than albumin was found in plasma and urine. In several carcinoma cases the α -globulins rather than the γ -globulin fraction showed a greater increase in the plasma and fluids.

Non lability of choline methyl and the role of choline oxidase in transmethylation. JACOB W. DUBNOFF, *California Institute of Technology, Pasadena, Calif.* The methyl groups of choline are not labile but become available for methionine formation from homocysteine only if the animal can oxidize choline to betaine. *In vitro* studies show that methionine formation is rapid from betaine, dimethylthetin, and certain derivatives of dimethylthetin both aerobically and anaerobically in all animals tested, but choline is effective only in those animals which have choline oxidase. While the aerobic synthesis of methionine from choline in these animals approaches that from betaine, anaerobic methionine formation from choline is relatively small or absent. Rabbit, guinea pig and chick, which do not have choline oxidase, do not form methionine from choline in liver and kidney homogenates aerobically or anaerobically. Inhibition of aerobic methionine formation from choline in rat by choline analogues parallels their effects on choline oxidase. There is no significant aerobic methionine formation from choline at pH 6.7 where its oxidation proceeds only to the aldehyde stage. The importance of choline oxidase may be to enable the animal to divert choline methyl into the general transmethylation scheme.

Thiocyanation of tyrosine. MARIE L. ASTERWOOD (by invitation) and JOHN L. WOOD, *Dept. of Chemistry, School of Biological Sciences, University of Tennessee, Memphis, Tenn.* Thiocyanation has been shown to interfere with the metabolism of tyrosine in the thyroid gland. This physical

activity has been suggested to be an interference of the 'metabolic antagonist' type. Studies on thyroid glands from animals given potassium thiocyanate labeled with radioactive sulfur indicate that the thiocyanate ion itself combines chemically with protein. The data, and the chemical properties of tyrosine and thiocyanogen, are consistent with the hypothesis that administered thiocyanate may react with tyrosine, by a mechanism similar to iodination, to form thiocyano derivatives. This point of view is supported by the thiocyanation of tyrosine *in vitro*. Tyrosine reacts with thiocyanogen (corresponding in state of oxidation to free iodine) in glacial acetic acid to form thiocyanotryosine. The compound has been characterized by ultimate analysis, optical activity, absorption spectrum, and by the formation of derivatives.

On the preparation and preservation of Fraction I from human plasma JOHN T. EDSALL, JOHN D. FERRY, and PETER R. MORRISON (by invitation). *Dept. of Physical Chemistry, Harvard Medical School, Boston, Mass.* In the preparation of Fraction I (the fibrinogen-containing and most insoluble major fraction of plasma as separated by ethanol precipitation, cf. Cohn, et al., *J. Am. Chem. Soc.*, 68: 459, 1946) from human plasma previous conditions of blood processing are particularly important and may be critical. Both short handling times and quick cooling of the blood are needed to insure a stable product. The optimal conditions for the separation from plasma are pH 7.3, 8% ethanol and -3°C . Although the gross purity of the fraction (60-65% fibrinogen) is not sensitive to pH, components are precipitated below pH 7.0 which greatly reduce the stability of the product. Fraction I is most conveniently stored as frozen precipitate, but is much less stable either in this form or as frozen solution than when stored in the dry state. In the latter form, and stored under vacuum, it has been successfully kept at room temperature for more than 4 years. It is less stable in air and more stable at low temperatures. Solutions of fibrinogen are less stable than albumin or globulin at both ordinary and elevated temperatures. They are more like the latter in their response to stabilizing agents. Testing procedures for Fraction I have been followed on a considerable series of bottled 'commercial' preparations. Criteria included total and relative amounts of fibrinogen, pH and buffering capacity, clotting times with thrombin and with calcium, stability of the solutions at 25° , 37° and 45° , and of a clot at 37°C .

Estimation of ergosterol with activated glycerol dichlorohydrin ROMOLA ETTINGER (by invitation) and Albert E. Sobel. *Polytechnic Institute and Jewish Hospital, Brooklyn, N. Y.* The reaction between Ergosterol and GDH (glycerol dichlorohydrin) was studied spectrophotometrically. Activated GDH (Sobel and Werbin, *Anal. Ed.*, 18: 570,

1946) containing 4% acetyl chloride produces a greenish yellow color suitable for the determination of ergosterol. Cholesterol and 7-dehydrocholesterol do not interfere. Ergosterol values obtained on brewer's yeast are similar to those with the SbCl_5 method (Lamb, Mueller and Beach, *Anal. Ed.*, 18: 187, 1946) but lower than the less specific ultraviolet absorption method. A new method of extraction was developed which is simple, reliable, requires small samples (i.e. 25 to 50 mg brewer's yeast) and permits rapid, simultaneous determinations. Specimen is placed in a glass stoppered tube, saponified with 1N alcoholic KOH, extracted three times with petroleum ether in this tube, extracts evaporated to dryness with N₂, dissolved in 1 ml of chloroform, treated with 4 ml of GDH reagent and after 20 minutes read in the spectrophotometer at 410 μ . Quantitative recoveries were made of known amounts of ergosterol added to the brewer's yeast.

The effect of ethionine on fat metabolism and on protein formation E. FARBER (by invitation), M. SIMPSON (by invitation), and H. TARVER. *Div. of Biochemistry, Univ. of California Medical School, Berkeley, Calif.* When DL-ethionine is injected into fasted rats fat rapidly appears in the liver so that in 12 hours the fat content is 14% (Control 6%). Fat continues to accumulate and the animals die within the next 24 hours. The appearance of fat in the liver is prevented by giving D, L or L-methionine but not by other amino acids such as L-lysine, DL-valine, glycine, or L-alanine in equimolar doses. Choline lowers the fat content to only 12.5%. Orally administered sucrose (5 gm) or glucose prevents the fat accumulation. The condition is either cured or at least markedly improved by giving methionine 12 hours after the ethionine. In short term *in vivo* experiments in which ethionine is injected along with labeled methionine (S^{35}) the uptake of the label into liver protein is greatly reduced during the next 3 hours (26 and 53% in different experiments). This inhibition of protein formation is reversed by equimolar doses of methionine. Sucrose given orally does not significantly effect the inhibition. Ethionine also inhibits the conversion of methionine to cystine *in vivo* and this inhibition is relieved by methionine injected in larger doses than are required to relieve the protein inhibition. Probably ethionine prevents the demethylation of methionine. In liver slices the effects of ethionine on protein metabolism are practically duplicated. The inhibition of methionine uptake depends on the ethionine concentration and is eliminated by methionine—best by the L-isomer. Ethionine also inhibits the uptake of glycine both *in vitro* and *in vivo*. Methionine *in vivo* relieves the inhibition.

Quantitative paper chromatography of penicillins II. Development of buffered strips with

organic solvent OLIVER B FARDIG and NANCY D BREED (introduced by S B BINKLEY) *Research Division, Bristol Laboratories, Inc., Syracuse, N Y* A paper strip chromatographic procedure has been developed whereby the commonly known penicillins were completely separated from one another by developing procaine citrate-buffered strips with amyl acetate for 15 to 18 hours. Filter paper strips were buffered the first part of their length with pH 5.2 procaine citrate, spotted with 0.5 to 2.5 μ of penicillin, equilibrated in a chamber saturated with respect to water and amyl acetate vapor, and developed in the same chamber. The dried developed chromatograms were placed on *Staph aureus*-inoculated trays which were then incubated to reveal the position of the individual penicillins. Two chromatograms of different concentrations of the same solution were placed on the same tray. Photographs of the incubated trays were made to facilitate calculation. The amount of penicillin present was determined from measurements of the maximum width of each zone on the photograph. Analysis of penicillin mixtures of known composition gave results in excellent agreement with the known values. No interference was observed in the determination of the penicillins in broth. The rate of movement of the penicillins along the strip increased in the order *p*-hydroxybenzylpenicillin, benzylpenicillin, 2-pentenylpenicillin, penicillin, and *n*-heptylpenicillin. The usual spread of the fast-moving *n*-heptylpenicillin was prevented by allowing this penicillin to move beyond the buffered portion of the paper strip. The separation of the penicillins, their rate of movement, and their compactness on the strips was influenced by the buffer, the solvent, and the conditions of development.

Glycolysis and the Pasteur effect on the sub-cellular level SILVIO FIALA (introduced by DEAN BURK) *National Cancer Institute, Bethesda, Md* Mouse sarcoma 37, when homogenized in 8.5% sucrose solution, yielded on 7 minutes centrifugation at 20,000g a pellet of large particles, and after 2-3 hrs at 20,000g a microsomal gel. Both fractions when washed and re-suspended in 8.5% sucrose, and after addition of fortifying factors (DPN 4×10^{-4} , ATP 8×10^{-4} , Nicotinamid 32×10^{-4} , Na pyruvate 8×10^{-3} , $MgCl_2$ 5×10^{-3} , $KHCO_3$ 2×10^{-2} , and glucose 0.5%, at pH 7.1) glycolyzed HDP but not glucose alone. Use of the Ringer solution results in a lowering of glycolytic activity. Under conditions mentioned there is no oxygen uptake in any fraction. The glycolytic activity of the large granules and microsomal fractions is independent of the presence of oxygen, but a small Pasteur effect in the supernate may occur. When either the large particles or the microsomal pellet is mixed with the supernatant, the aerobic glycolysis (N_2 , CO_2) of the combination

is equivalent to the sum of the glycolysis of each fraction run separately. However, under aerobic conditions (O_2/CO_2) the glycolysis of the combined fractions is lower than of any single fraction. Mixing the particulate elements with the supernatant thus results in the appearance of a pronounced Pasteur effect. Normal mouse liver particulates and the supernatant fluid (after removal of microsomes) showed the same mutual interaction in regard to Pasteur effect but quantitative differences occurred. In the attempt to determine the centrifugal force sufficient to concentrate the remaining glycolytic activity in the supernatant fluid (after removal of formed elements) in the experiments done with Dr G Kegeles (National Cancer Institute) it has been found that after a run of 4 hours at 164,000g the activity in the bottom layer was 2x that of the top layer of the centrifuged sample.

Influence of estrogenic hormones on b-glucuronidase in the human WILLIAM H FISHMAN and LESTER D ODELL (by invitation) *Depts of Surgery and Biochemistry, Obstetrics and Gynecology, Univ of Chicago, Chicago, Ill* In previous work a relationship between the metabolism and action of the estrogenic hormones and b-glucuronidase was indicated. In castrate female mice, the uterine glucuronidase responds by an increase in its activity following the injection of estrogenic substances. In pregnant women, the serum b-glucuronidase becomes elevated. Additional experiments have now been done in humans with a view to exploring the extent of the relationship of estrogen metabolism to b-glucuronidase activity. The following observations have been made. In 15 post-partum women receiving no medication, whether lactating or non-lactating, the serum b-glucuronidase falls from approximately 500 μ /100 cc regularly to non-pregnancy levels by the sixth day after parturition. On the other hand, the decline in glucuronidase was much smaller and more gradual in post-partum women receiving stilbestrol (5 to 25 mg/day for periods of 10 days). Endometrial biopsies were obtained from 33 women at various days of the normal menstrual cycle and assayed for b-glucuronidase activity. The enzymic activity increased during the first two-thirds of the menstrual cycle, followed by a decline, particularly in the last three days of the cycle. The presence or absence of progestational endometrium seemed to bear little reference to these changes. From these and other observations, it is felt that estrogen may be at least one of the factors which influence the b-glucuronidase level in the serum and in uterine endometrium.

Amylase and lipase in the intestinal lymph of the rat E V FLOCK and J L BOLLMA *The Mayo Foundation, Rochester, Minn* Lymph is collected continuously from the small intestine of the rat after cannulation of the main lymphatic vessel with polyethylene tubing. The enzyme activities

24 hours prior to the operation, and on the day following received 2 meals of either a fat-free or high-fat diet by stomach tube. Lymph collected overnight before the first meal and at 2, 4 and 18 hour intervals thereafter was analyzed for amylase and lipase activity. The amylase was determined by the copper reduction method of Somogyi and the lipase (tributyrylase) by the method of Goldstein and Roe. The amylase activity of the intestinal lymph was lower than that of the plasma in the fasting rat. The response to feeding was slight and variable. If an increase was found, the level reached was generally lower than that of the plasma of the fed rat. The average hourly output of amylase in the lymph increased markedly only during the first 2 hours after feeding and this was at least in part due to the increased rate of flow. Higher values for tributyrinase activity were found throughout the 24 hour feeding period studied in the intestinal lymph of rats fed the high-fat diet than during fasting or after feeding of the fat-free diet. The average hourly output of lipase in the lymph of rats fed the high-fat diet was also increased throughout the 24 hour period whereas in rats fed the fat-free meals an increase was found only during the first 2 hours after feeding.

A new P-free and S-free brain lipid. J. FOLCH and S. ARSOVE (by invitation) *McLean Hospital, Waverley, Mass and Harvard Medical School, Boston, Mass.* A new lipid has been found to be present in grain. It appears to be P-free and S-free and to have as a constituent an as yet unidentified primary amine which becomes water-soluble after short-time acid hydrolysis. The new lipid has been partially purified. The preparation obtained is still contaminated by phosphatides (0.15 per cent P) and sulfatides (0.25 per cent S). The constituents of the new lipid appear to be sphingosine (1.1 per cent sphingosine N) or a sphingosine-like substance, carbohydrate (20 per cent as galactose), an unidentified primary amine (1.1 per cent water-soluble NH_2 after acid hydrolysis) and unsaponifiable substances (only small amounts of fatty acids are obtained from it after saponification). The constituent amine is not neuraminic acid (Klenk, E, *Ztschr f physiol Chem* 268 50, 1941 and it is linked to the rest of the molecule by its NH_2 -group, since the intact lipid does not exhibit any free NH_2 -group. The new lipid is soluble in acetic acid, and in CHCl_3 CH_3OH mixtures at room temperature and insoluble in the latter at -10° . The method of isolation which has yielded a partially pure product is based on these solubilities. The new lipid appears to be a contaminant of a large number of cerebroside and sphingomyelin preparations that have been analyzed.

Cholesterol studies on lyophilized chicken serum. J. C. FORBES and G. H. L. DILLARD (by invitation) *Dept of Biochemistry, Medical College*

of Virginia, Richmond, Va. The serum cholesterol of both male and female chickens of varying ages has been fractionated in a manner previously described (*Proc Soc Exper Biol & Med* 68 240, 1948). The results indicate that a large percentage of the cholesterol of lyophilized serum from old hens is extracted by cold chloroform in 3 hours, behaving in this regard very similarly to the serum of nephrotic patients and hypercholesterolemic rabbits. Old hens, however, show this high degree of cholesterol extractability even though the total cholesterol concentration is normal. The sera of young chickens and old roosters show a low value for this 'readily extractable fraction'. Studies on the effect of a high fat diet on these fractions in roosters of various ages will be presented also.

Synthesis of some benzoylamino acid anilides as catalyzed by papain. SIDNEY W. FOX, FREDERICK N. MINARD (by invitation), HARRY WAX (by invitation), CORNELIUS W. PETTINGA (by invitation), and JACQUETTA STRIFERT (by invitation) *Chemical Laboratory, Iowa State College, Ames, Iowa.* The synthesis of anilides from 4-benzoyl-DL-amino acids and aniline, as catalyzed by papain, has been studied in consolidated experiments. The alanine and leucine derivatives were considerably preferred in reactivity over glycine and valine. Benzoylglycine showed relatively moderate reactivity and benzoylvaline barely reacted. Benzoylvaline was the only valine derivative of several (formyl, acetyl, 3,5-dinitrobenzoyl, benzoyl, phthaloyl, and *o*-carboxybenzoyl)-DL-valine, which gave the acylamino acid anilide. The last 2 valine derivatives yielded N-phenylphthalimide, which was also the product isolated from *o*-carboxybenzoyl-DL-valine and aniline in either the absence or presence of enzyme. The relative non-reactivity of benzoylvaline was not due to the presence of the D-isomer, as shown by approximately equal reactivity of the L-component in the L- and DL-forms. These results are of interest in relation to the observation of Roche and Mourgue that papain liberates much more leucine than valine from casein. Roche and Mourgue ascribed this behavior to position of residues in the substrate molecules, in the present work the results can be explained on the basis of greater reactivity of leucine bonds than of valine bonds in papain-catalyzed systems. Hydrolytic data for papain and compounds containing the same residues has been obtained. The retarding effect of various substances, such as iodoacetic acid, p-quinone, and 2,3,5-triphenyltetrazole, upon some anilide syntheses has been studied.

Mechanism of reversible inactivation of lysozyme by iodine and sulfite. H. FRAENKEL CONRAT *Western Regional Research Laboratory, Bureau of Agricultural and Industrial Chemistry, Agricultural Research Administration, U. S. Dept of*

Agriculture, Albany, Calif Meyer et al (J Biol Chem 113 303, 1936) showed that lysozyme loses and regains activity upon treatment with iodine and sulfite, respectively. It has now been found that the effect of a great excess of iodine is partly reversible only after 10–120 minutes at or above neutrality. Reactivation was achieved also with thioglycol and was found associated with a loss in bound iodine, equivalent to 60–100% of the histidine content of lysozyme. Proteins of greatly varying histidine contents, when treated with iodine and sulfite under similar conditions, contained reversibly bound iodine in proportion to their histidine contents. From this and other evidence it is concluded that the reversibly inactivated derivative is formed first and probably contains a labile α -iodohistidine residue, whereas the irreversibly inactivated derivative is formed later by rearrangement of the α -iodohistidine into a stable ϵ -iodo form. The concomitant iodination of some phenolic groups appeared to cause little inactivation, but when over 2 iodine equivalents (per mole lysozyme) were introduced into these groups, the activity was greatly lowered. The incipient oxidative destruction of tryptophan residues (less than 1 per mole) appeared reversible by early reduction. Lysozyme contains no $-SH$ group.

Pteroylglutamic acid deficiency in the dog as produced by 'x-methyl' pteroylglutamic acid
A. L. FRANKLIN (by invitation), T. H. JUKES, E. L. R. STOKSTAD, and M. BELT (by invitation)
Lederle Laboratories Division, American Cyanamid Company, Pearl River, N. Y. Dogs were kept on wire floors in individual cages and were fed a purified diet with pteroylglutamic acid (PGA) omitted and with a crude PGA antagonist, 'x-methyl' PGA, added. The dogs grew slowly or lost weight and developed a condition marked by emaciation, alopecia, anemia and ulceration of the skin. A slight hemopoietic response with a small reticulocyte rise was obtained when liver extract was injected. However, when PGA was administered a marked response was obtained together with a prompt gain in weight and with growth of hair in the denuded areas. Dogs appeared normal when they received the diet with the antagonist omitted or with sufficient PGA added to reverse the antagonist as judged from experiments with other species.

Observations on the equilibrium between glycine and glycyglycine in the presence of liver peptidase
IAN D. FRANTZ, JR., ROBERT B. LOFTIN, and ANN S. WILNER (introduced by FRITZ LIMANN)
Medical Laboratories of the Collis P. Huntington Memorial Hospital of Harvard Univ., Massachusetts General Hospital, Boston, Mass. Methods have been worked out which permit the study of equilibrium mixtures of glycyglycine and glycine. These are based on the use of long-lived radioactive carbon, for the detection and

measurement of small amounts of the reactants, and chromatography of starch, for their separation. In a typical experiment, labeled glycine is incubated at 38° with a peptidase preparation made from rat liver. The pH is held at approximately 7.6 by means of a borate buffer. After 48 hours the reaction is stopped. Glycyglycine is added as carrier, and the reaction mixture is placed on a column of potato starch. 2.1 normal propanol-water is passed through the column, and the effluent is analyzed by the photometric ninhydrin method of Moore and Stein (*J Biol Chem* 178 367, 1948). The glycine and glycyglycine peaks are each pooled and analyzed for radioactivity. With glycine concentrations as high as 1 molar, the experiment has also been carried out with the addition of carrier, allowing confirmation of the results independent of the use of radioactive carbon. This possibility exists because of the high resolving power of the column, and its large capacity for glycine. Thus, 30 mg of glycine may be completely separated from 60 μ g of glycyglycine, formed during the reaction. The free energy of the peptide bond as determined in this way is in fair agreement with the value calculated by Borsook and Dubnoff, based on thermal measurements (*J Biol Chem* 132 307, 1940).

Purification and properties of ovomucoid
E. FREDERICQ (by invitation) and H. F. DEUTSCH
Depts. of Physical and Physiological Chemistry, Univ. of Wisconsin, Madison, Wis. The solubility of ovomucoid in trichloroacetic acid solution has been utilized for its isolation. In an egg white system of 5% sodium trichloroacetate and pH 3.5, the major portion of the ovomucoid remains in solution while the other proteins are precipitated almost quantitatively. The ovomucoid is then recovered by precipitation at an ethanol concentration of 65% and temperature -7°C . The product consists of 2 components which are closely related electrophoretically. The major component comprises from 90–95% of the total protein. It may be separated in relatively pure form from 1% solution by several precipitations at pH 3.2, ionic strength 0.01, and ethanol concentration 42%. On electrophoresis this protein behaves as a single component over a considerable pH range and has an isoelectric point at pH 3.8. In experiments performed in the region of the isoelectric point some electrophoretic inhomogeneity is evident. Its electrophoretic mobility in diethylbarbiturate buffer at pH 8.6 and ionic strength 0.1, is 4.3×10^{-5} cm² volt⁻¹ sec⁻¹. Ovomucoid which has been isolated by electrophoresis gives a sedimentation constant of $s_{20,w} = 2.9$ s. This value is also obtained with the ovomucoid separated by fractionation. Preliminary carbohydrate analyses of the crude ovomucoid show a level of approximately 10% calculated from competitive antagonists of throxine and structurally related compounds. I. W. F. 1

invitation) and RICHARD J WINZLER *Dept of Biochemistry and Nutrition, Univ of Southern California School of Medicine, Los Angeles, Calif* Thyroxine antagonism by several new compounds has been observed using the amphibian metamorphosis test system described by Frieden and Winzler (*J Biol Chem*, 176 155, 1948) The competitive nature of these inhibitors was shown by the relative constancy of the molar ratio of inhibitor to thyroxine required for reduction of the thyroxine effect by 50%, and by adherence of the data to the more rigorous equation of Lineweaver and Burk (*J Am Chem Soc*, 56 658, 1934) Reduction of the thyroxine effect by 50% by O-benzyl-3,5-diiodo-DL-tyrosine was achieved with molar ratios of 37, while the N-acetyl derivative, described by Woolley (*J Biol Chem*, 164 11, 1946), required a ratio of 550 The benzyl, p-nitrophenylethyl, and methyl ethers of 3,5-diiodo-4-hydroxybenzoic acid required ratios of 8, 75, and 150 respectively for similar effects Specificity of these antagonisms was indicated by the absence of any inhibition of thyroxine by structurally related compounds, goitregens, and other substances Inhibition of the thyroxine-like activity of 3,5-diiodo-4-(3',5'-diiodo-4'-hydroxyphenoxy)benzoic acid was obtained at the same molar ratios with several of the above thyroxine antagonists However, no inhibition of the activity of 3,5-diiodo-4-(4'-hydroxyphenoxy)aniline was observed at very high molar ratios Assuming that thyroxine-like active compounds act by serving as a prosthetic group or coenzyme for some enzyme system or systems, these data lend support to suggestions that the side chain of thyroxine serves as an enzyme-associating locus while the ortho-diiodo hydroxy phenyl group acts as a 'functional' locus of the molecule

Liver regeneration in the adrenalectomized rat CHARLES E FRIEDGOOD (by invitation), HARRY M VARS and JOAN W ZERBE (by invitation) *Harrison Dept of Surgical Research, Schools of Medicine, Univ of Pennsylvania, Philadelphia, Penna* In continuing previous studies of N metabolism and liver protein regeneration male Wistar rats have been adrenalectomized at the time of partial hepatectomy Saline drinking water was available throughout the 2-week postoperative period Total net N balances and new liver protein formed have been determined Adrenalectomy reduced the amount of liver protein regeneration in rats both protein-fed and protein-depleted before operation Whole adrenal extract administered to such rats restored their ability to regenerate new liver protein Rats, protein-depleted for 2 weeks and subjected to the double operation, were given daily injections of desoxycorticosterone acetate, 11-dehydrocorticosterone acetate and 11-dehydro, 17-hydroxycorticosterone (acetate) during the 2 week postoperative period At the dose levels used,

all stimulated hepatic protein metabolism and caused the same or greater regeneration of new liver protein than occurred in animals with intact adrenals DOCA caused the greatest increment, accompanied by evidence of hormonal overdosage 11-dehydrocorticosterone appeared to be slightly more active than 11-dehydro, 17-hydroxycorticosterone

Flavoenzyme catalysis Sulfhydryl character of the d-amino acid oxidase W R FRISSELL (by invitation), E C WEINBACH (by invitation), R C COWGILL (by invitation), and LESLIE HELLERMAN *Dept of Physiological Chemistry, Johns Hopkins Univ School of Medicine, Baltimore, Md* In earlier studies (1940-42) we observed that the activity of the d-amino acid oxidase of lamb kidney is suppressed by p-chloromercuribenzoate (Hellerman in *Cold Spring Harbor Symposia on Quantitative Biology*, 7 165, 1939) and by porphyrindine Notes have appeared from other laboratories on effects of sulfhydryl-binding agents upon such oxidases Of outstanding biochemical importance is the role of 'available' protein-sulfhydryl groups essential to the activity of certain enzymes Although p-chloromercuribenzoate and also iodosobenzoate can attack the separated protein of lamb d-amino acid oxidase, and, less reversibly, pig kidney oxidase, it is demonstrated that these reagents in low concentration may function instead as competitive inhibitors for the substrate It is essential, in these studies, to recognize that certain flavoenzymes dissociate, further, that the aforementioned 'sulfhydryl-reagents' function as such, and, independently, as typical unsaturated anionic inhibitors (*Transactions of the Second Conference, Biological Antioxidants*, 78, 1947) Any labile sulfhydryl groups of these flavoenzymes appear to be 'protected' by FAD Certain reagents attack protein-sulfhydryl irreversibly, in the thermodynamic sense Cogent evidence is revealed in experiments with phenylmercuric acetate Kinetic studies show that the inhibition observed here is not substrate-competitive The action of authentic competitive inhibitors, e.g cinnamate ion, may be superimposed upon that of the mercurial The results in no way support a concept that enzyme-sulfhydryl here is concerned directly with substrate binding or is involved in substrate 'activation'

Preparation of deuterated steroids DAVID K FUKUSHIMA (by invitation) and SEYMOUR LIEBERMAN *Dept of Steroid Biochemistry, Sloan-Kettering Institute for Cancer Research, New York City* For the purpose of studying some problems in steroid metabolism we have investigated the preparation of deuterium labeled steroids Two general methods for the introduction of stably bound deuterium into Δ^4 -steroids have been developed The first of these involved halogenation with bromosuccinimide at C₇ of a steroid ester followed by cataly-

tic reduction with deuterium in the presence of palladium or deuterized Ranney nickel. An alternate procedure, which was advantageous in that 2 deuterium atoms were incorporated, consisted in the conversion of a Δ^5 -7-ketosteroid ester to the corresponding mercaptol by condensation with ethanedithiol. Upon desulfurization with deuterized Raney nickel, the cyclic thioacetal was converted to the Δ^5 -7,7-d₂-steroid. By these methods deuterium labeled cholesterol and Δ^5 -androstenediol-3 β ,17 α -acetate-3,benzoate-17, an intermediate in the synthesis of testosterone, were prepared.

Hepato-renal factors in circulatory homeostasis
XXIV. Conditions leading to aerobic formation of VDM by liver. ROBERT F. FURCHGOTT, BENJAMIN W. ZWEIFACH (by invitation) and EPHRAIM SHORR (by invitation). *Dept. of Medicine, Cornell Univ. Medical College and The New York Hospital, New York City.* Previous experiments from this laboratory have shown that normal liver slices form the vasodepressor, VDM, only under anaerobic conditions, on aerobic incubation, VDM formation is inhibited and VDM added to the incubation medium is inactivated. In contrast, livers from animals in irreversible shock sustain a profound impairment in the capacity to inactivate VDM on aerobic incubation. A similar impairment is shown by normal liver slices following prior exposure to anaerobiosis. In a recent extension of these studies, it has been observed that liver slices from dogs in irreversible shock not only lose their capacity to inactivate VDM aerobically, but also continue to form VDM under aerobic conditions. This was also the case with normal liver following an appropriate period of anaerobic exposure, anaerobic incubation of normal liver (dog, rabbit) for one hour at 37.5°C usually results in the continued elaboration of VDM on the restoration of aerobic conditions. With both types of liver preparations, the rate of aerobic VDM formation is comparable to that of normal liver slices under anaerobic conditions. Respiratory studies of liver slices, treated so as to form VDM aerobically, revealed no relation between the loss of ability to inhibit aerobic VDM formation and changes in oxygen consumption. The significance for shock of this derangement in VDM metabolism resides in the fact that the temporary restoration of aerobic conditions within the liver by transfusions would not, per se, prevent the continued elaboration of VDM and the persistence of the decompensatory effects of this vasodepressor principle on the peripheral circulation.

Chloride diarrhea and systemic alkalosis in potassium deficiency. LYTT I. GARDNER, ELSIE A. MACLACHLAN, MARY L. TERRY, JANET W. McARTHUR and ALLAN M. BUTLER (introduced by RALPH W. MCKEE). *Children's Medical Service, Massachusetts General Hospital, and the Dept. of Pediatrics, Harvard Medical School, Boston, Mass.*

Severe potassium deficiency was produced in 160 to 175-gm rats by use of a diet containing 0.003% K and 0.7% sodium. K added to the diet produced excellent growth in controls. Rats fed the deficient diet gained weight slowly for 35–40 days, then diarrhea began, followed by anorexia, wasting and death between 60 and 120 days. Muscle K was reduced almost 50%. Hypochloremic alkalosis was present. Metabolic studies while on the deficient diet showed negative K and Cl, and positive Na balances. A single injection of 1.0 mEq K as K_2HPO_4 produced transitory reversal of these balances and temporarily arrested the diarrhea and anorexia. The Cl and Na balances lagged 3–4 days in their reversal. Fecal excretion of Cl progressively diminished for 6 days post-injection. Urinary Cl decreased for 3 days post-injection, then abruptly increased on the 4th day, coincident with marked Na diuresis. This may reflect the extrusion of intracellular Na, covered in the urine by the anion Cl, cf. Conway and Hingerty, *Biochem. J.* 42: 372, 1948. On the deficient diet daily Cl excretion was double that on the control diet. There was 4 times as much Cl in the feces of the deficient animal as in the feces of the control. Even during diarrhea there were twice as many mEq of Cl as Na in the feces of the deficient animal. The reported cases of congenital alkalosis with diarrhea, and 2 cases of ulcerative colitis seen at this hospital, show many metabolic similarities to the above findings, which suggest deficit of intracellular K. The etiologic role played in these syndromes by adrenal overproduction of the 11-desoxycorticosteroid (DOCA) type of hormone, known to produce K deficiency when injected, is under investigation.

Inhibition of hyaluronidase by blood serum and bile constituents. DAVID GLICK, LEE W. WATTENBERG (by invitation) and ERICK Y. HAKANSON (by invitation). *Dept. of Physiological Chemistry, Univ. of Minnesota Medical School, Minneapolis, Minn.* In an attempt to determine the origin of the hyaluronidase inhibitor in blood serum, 29 organs and bile, urine, and amniotic fluid of the rabbit, in addition to human saliva, milk, and spinal fluid, and hog synovial fluid were tested. No inhibitory activity was found by the viscosimetric method in any of them except bile and urine. The inhibitor in the latter fluids was heat stable and active in the presence of phosphate, thus differentiating it from that in serum. A variety of hemoglobin derivatives, bile salts, and sterol hormone conjugates have been found to inhibit hyaluronidase. The additive value of the individual inhibitions of any one of the compounds and that of serum was always greater than the observed inhibition of a combination of the two. The data would indicate that the hemoglobin derivatives and bile salts inhibited the serum inhibitor, and that serum also reduced the inhibition

of these compounds. Exceptions to this mutually antagonistic effect were observed with certain of the sterol conjugates. Stercobilin was unique in that it did not inhibit hyaluronidase under the conditions used while it did inhibit the serum inhibitor. Studies of the variations of the human serum inhibitor during the menstrual cycle revealed highest levels during actual menstruation and lowest during subsequent and middle phases of the cycle. No significant change was found during pregnancy or labor, but a marked post-partum rise was observed which reached a maximum from the 2nd to 5th days after delivery.

Amino acid composition of casein, α -casein and β -casein. WILLIAM G GORDON, WILLIAM F SEMMETT (by invitation), and MYRON MORRIS (by invitation). *Eastern Regional Research Laboratory, Philadelphia, Penna.* The investigation of the comparative amino acid composition of whole casein, α -casein and β -casein previously reported in part (*Federation Proc* 6 255, 1947) has been completed. The analytical results, expressed as grams of amino acid yielded by 100 gm of dry, ash-free protein, follow

	Whole Casein	α Casein	β -casein
Glycine	2.7	2.8	2.4
Alanine	3.0*	3.7*	1.7*
Valine	7.2	6.3	10.2
Leucine	9.2	7.0	11.6
Isoleucine	6.1	6.4	5.5
Proline	11.3	8.2	16.0
Phenylalanine	5.0	4.6	5.8
Cystine	0.34	0.43	<0.1
Methionine	2.8	2.5	3.4
Tryptophan	1.2	1.6	0.65
Arginine	4.1	4.3	3.4
Histidine	3.1	2.9	3.1
Lysine	8.2	8.9	6.5
Aspartic acid	7.1	8.4	4.9
Glutamic acid	22.4	22.5	23.2
Amide nitrogen	1.0	1.0	1.0
Serine	6.3	6.3	6.8
Threonine	4.0	4.9	5.1
Tyrosine	6.3	8.1	3.2

* Provisional

Calculation of the data on the basis of N distribution shows that 101.5% of the whole casein N, 101.8% of the α -casein N and 103.4% of the β -casein N have been accounted for in terms of recognized amino acids and amide groups.

Effect of N,N-dibenzyl- β -chloroethylamine (dibenamine) on blood sugar response to insulin and epinephrine. R. LORIMER GRANT. *Division of Pharmacology, Food and Drug Administration, Federal Security Agency, Washington, D. C.* The subcutaneous injection of dibenzyl- β -chloroethylamine hydrochloride 18-20 hours before the injection of an insulin-containing drug appeared to prolong the hypoglycemic effect of the insulin. Epinephrine injected during the hypoglycemia was significantly inhibited as an antidote to the insulin. Nickerson and Goodman (*J Pharmacol and Exper Therap* 89 167, 1947) found that dibenzyl- β -chloroethyl-

amine produced no significant inhibition of the epinephrine-induced blood sugar rise in rabbits. We repeated their experiment using a 12 rabbit cross-over test and demonstrated a significant inhibition of the epinephrine-induced blood sugar rise following treatment with dibenzyl- β -chloroethylamine. The effect of dibenzyl- β -chloroethylamine on the response to insulin is apparently due to inhibition of endogenous epinephrine or other sympathomimetic factors which increase the rate of glycogenolysis.

Studies on hypoxanthine synthesis in pigeon liver with labeled formic acid. G. ROBERT GREENBERG (introduced by HARLAND G. WOOD). *Dept of Biochemistry, School of Medicine, Western Reserve Univ., Cleveland, Ohio.* It previously has been shown that HC^{14}OOH is incorporated into hypoxanthine in pigeon liver homogenates (*Arch Biochem* 19 337, 1948). Further studies have been conducted to elucidate the intermediate steps in this synthesis using HC^{14}OOH to trace the reaction. Approximately 60-70% of formic acid was accounted for in hypoxanthine but almost 100% of the formic acid disappeared during the same period of time. This suggested that the HC^{14}OOH had either entered into other reactions or was present in intermediate compounds involved in the synthesis of hypoxanthine. Small volumes of the reaction mixture were subjected to filter paper chromatography. The paper strips were cut into 0.5 or 1 cm sections and the radioactivity of each determined. Two distinct radioactive compounds migrated down the paper. One of these has been identified as hypoxanthine and contains the majority of the radioactivity. The other component has a distinctly different absorption spectrum than that of hypoxanthine. The homogenate may be separated into 2 components, the washed particles and the supernatant. Neither fraction shows much activity alone but in combination almost the full synthetic ability is restored. Either component is inactivated by boiling.

Short-term pyridoxine deprivation in two human subjects. LOUIS D. GREENBERG, DAVID F. BOHR (by invitation), HOPE McGRATH (by invitation) and JAMES F. RINEHART (by invitation). *Dept of Pathology, Univ of California Medical School, San Francisco, Calif.* Studies of the blood pyridoxine and the urinary excretion of pyridoxine, 4-pyridoxic acid, xanthurenic acid, tryptophan and N-methylnicotinamide were carried out on two human subjects who persisted on a pyridoxine deficient diet for three weeks. The diet consisted of casein, sucrose, corn oil and salts supplemented with the known vitamins excepting pyridoxine, p-aminobenzoic acid, vitamin K and tocopherols. By the administration of extra pyridoxine prior to the withdrawal of the vitamin, the blood pyridoxine concentration was increased from initial

values of 15 to 20 μg to values of 41 to 71 μg %. At the end of the deficient period the levels had fallen to approximately the initial values or lower. The urinary pyridoxine and 4-pyridoxic acid paralleled each other, rising and falling during periods of administration and depletion of the vitamin, respectively. At the end of 2-3 weeks of depletion, xanthurenic acid excretion following 10 gm doses of DL-tryptophan was markedly increased and returned to low levels after supplementation with pyridoxine (10-15 mg daily) for one week. The urinary excretion of tryptophan as measured microbiologically was not significantly altered by deficiency, but chemical determination of tryptophan revealed that large quantities of tryptophan or an indole derivative appeared in the urine during the depletion period when test doses of DL-tryptophan were fed. Excretion of the metabolite remained high despite supplementation of the experimental diet with pyridoxine for one week. In confirmation of the work of others, an increased excretion of N-methylnicotinamide was observed after the feeding of tryptophan.

Effect of aromatic hydrocarbons on the metabolism of exogenous sulfur amino acids HELMUT R. GUTMAN (by invitation) and JOHN L. WOOD, *Dept of Chemistry, School of Biological Sciences, Univ of Tennessee, Memphis, Tenn.* The changes in urinary sulfur distribution produced by administration of aromatic hydrocarbons to rats were studied after injection of L-cystine or DL-methionine labeled with radioactive sulfur. The labeled total sulfur, inorganic sulfate, and chloroform-extractable sulfur-containing compounds in the urines were estimated by radioactivity measurements. Fifteen % of the sulfur was recovered in the urine 24 hours after injection of 10 mg of L-cystine and was chiefly in the form of inorganic sulfate. When 150 mg of bromobenzene were administered simultaneously, the amount of labeled total sulfur excreted appeared in the urine as chloroform-extractable sulfur at the expense of inorganic sulfate. The radioactive sulfur in this fraction was incorporated into bromophenylmercapturic acid since, following the addition of unlabeled bromophenylmercapturic acid to the urine, radioactive bromophenylmercapturic acid was recovered. Twenty % of S^{35} administered as DL-methionine was found in the urine in the form of inorganic sulfate after 24 hours. The administration of bromobenzene caused an increase in the total excretion of the injected S^{35} to 60% without appreciable change in the inorganic sulfate. The increase in excreted S^{35} was not accounted for by the mercapturic acid found but by other organic sulfur compounds not extractable by chloroform. The studies will be extended and correlated with alterations in sulfur metabolism produced by carcinogenic hydrocarbons.

Study of the carbohydrate-regulating hormone of hog adrenal extract WILLIAM J. HAINES (by invitation), RICHARD H. JOHNSON (by invitation), MARI P. BRUNNER (by invitation), MARVIN L. PABST (by invitation), and MARVIN H. KUIZENGA, *Research Laboratories, The Upjohn Company, Kalamazoo, Mich.* In 1933 Grollman reported that autolysis of beef adrenal tissue caused a significant decrease in the recovery of cortical hormone activity of the survival-growth type. However, subsequent biochemical studies on adrenal extracts, including those resulting in the isolation of 28 pure steroids, appear to have been done with adrenal glands collected by the usual slaughter-house procedures. The large quantities of tissue required in these earlier studies would seem to have prohibited the use of specially-collected glands. More recently we have developed techniques of isolation and identification which allow rather complete characterization of cortical hormone from relatively small amounts of adrenal tissue. These methods have now been applied to the investigation of the carbohydrate-regulating hormone of quick-frozen hog adrenals, in which autolytic changes have been greatly reduced. Comparison of this material, at various stages in its purification, with that obtained routinely from glands collected by the usual procedures, indicates some of the effects of autolysis. The neutral, composite extract from quick-frozen gland contained 120% more bioactivity (liver-glycogen deposition) than that from regular gland. Five hundred mg (10-kg gland) of it gave a normal benzene-water distribution after 2 cycles. Long standing in this system caused a 47% loss of activity. Five hundred fifty mg (11-kg gland) when chromatographed over MgSiO_3 , wherein bands were characterized by optical rotation, formaldehyde-forming capacity, and infrared absorption, yielded 70 mg of 17-hydroxycorticosterone, or 4 times the amount obtained from normal gland. Further characterization of the carbohydrate-regulating hormone are discussed.

Blood changes in acute amino acid deficiencies W. KNOWLTON HALL, LESTER L. BOWLES (by invitation) and V. P. SYDENSTRICKER (by invitation), *Depts of Biochemistry, Microscopic Anatomy and Medicine, Univ of Georgia School of Medicine, Augusta, Ga.* In order to investigate the blood changes which result from amino acid deficiencies, litter mate Wistar-strain rats were placed on diets devoid of one of the indispensable amino acids or on control diets. The deficient diets contained 3 times the minimum requirement of the other indispensable amino acids. Blood was obtained for counts and analyses by sacrifice of the animals and the values obtained with the different groups were compared. Except for some animals which were sacrificed at the beginning of the experimental period, the animals remained on the

diets until the symptoms of the deficiency became extreme. In rats fed a phenyl-alanine-deficient diet there was a reduction in blood volume although the blood counts and plasma protein levels were normal. There was a marked reduction in the number of reticulocytes. In valine deficiency the reduction in blood volume was less marked, there was a slight reduction in plasma protein level and the blood from most of the rats seemed devoid of reticulocytes. In isoleucine deficiency there was a reduction in blood volume, plasma protein levels and the reticulocyte count. These changes may be compared with the extreme hypoproteinemia, reduced blood volume and moderate anemia observed in deficiencies of threonine or protein. There was little difference between control rats fed the mixture containing only the indispensable amino acids and those fed a comparable level of an amino acid mixture similar to casein.

Mode of action of parathormone PHILIP HANDLER, W. J. A. DEMARIA (by invitation) and D. V. COHN (by invitation) *Depts. of Biochemistry and Pediatrics, Duke Univ. School of Medicine, Durham, N. C.* The intravenous administration of commercial parathyroid extract to dogs consistently resulted in an increased flow of a relatively alkaline urine containing considerably more sodium, bicarbonate and phosphate than the control urines. In some animals this phenomenon was immediately apparent while in others there was a lag period of 15-40 minutes. Studies of inulin and p-aminohippurate clearances revealed that the diuresis occurred simultaneously with a marked rise in renal blood flow and glomerular filtration. These in turn appeared to be secondary to a rise in systemic arterial blood and pulse pressures. The lag period occurred only in those dogs in whom parathormone administration induced a temporary shock-like state with low blood pressure, glomerular filtration and renal plasma flow. In no instance did the parathormone function by actually inhibiting renal tubular reabsorption of sodium, bicarbonate, chloride or phosphate, the altered composition of urine being due solely to the increased glomerular filtration consequent upon the rise in blood pressure and renal plasma flow. Studies are now in progress to determine whether the pressor principle in parathyroid extract is identical with the calcium mobilizing hormone or whether it is an artifact created during the extraction procedure.

Enzymatic hydrolysis of carnosine and related peptides H. THEO HANSON (by invitation) and EMIL L. SMITH *Laboratory for the Study of Hereditary and Metabolic Disorders and the Depts. of Biochemistry and Medicine, Univ. of Utah School of Medicine, Salt Lake City, Utah.* Liver, spleen, and kidney of the rat, and swine kidney are excellent sources of an enzyme, carnosinase, which

hydrolyzes carnosine β -alanyl-L-histidine. The swine kidney enzyme has been partially purified. Carnosinase is a metal-protein as indicated by the inhibition produced by cyanide, sulfide, and cysteine. Although both Mn^{++} and Zn^{++} activate the enzyme, it is likely that Zn^{++} is the naturally-occurring metal. This is suggested by the similarity of the Zn^{++} -enzyme and the unactivated preparation with respect to pH of optimal activity, poor stability at 40° in absence of substrate, and insensitivity to phosphate and citrate. At 0.05 M carnosine, the hydrolysis follows the kinetics of a zero order reaction, and the rate is proportional to the enzyme concentration over a range of at least 1-12. The optimal action with Mn^{++} is at pH 8.0-8.4, with Zn^{++} at 7.8-7.9, and without added metal at 7.4-7.5. The hydrolysis of carnosine cannot be attributed to any previously described protease. In addition to L-carnosine, the enzyme rapidly hydrolyzes both L and D-alanyl-L-histidine, and glycyl-L-histidine while L- α -amino-butyl-L-histidine, and glycyl-L-histidinamide are hydrolyzed more slowly. D-Carnosine, β -L-aspartyl-L-histidine, carbobenzoxy-L-carnosine, and carbobenzoxyglycyl-L-histidinamide are relatively resistant to the enzyme. These data indicate that carnosinase is an exopeptidase of dipeptidase or aminopeptidase specificity.

Application of micro methods to the study of steroid metabolism J. D. HARDY (by invitation), HILDEGARD WILSON (by invitation) and KONRAD DOBRINER *Sloan-Kettering Institute for Cancer Research and the Dept. of Physiology, Cornell Univ. Medical College, New York City.* The detailed study of the steroid hormone metabolites in the urine of healthy and diseased persons has been possible in the past with long term collection periods. By the use of infrared spectrometry as a method for the identification of the individual steroids in amounts of 1-3 mg the period of urine collection was shortened. A further improvement of this specific method of analysis was the development of a microcell for routine use. The cell has a volume of 0.03 ml, and is filled by capillary action. It is designed to be used immediately in front of the slit of a Perkin-Elmer spectrometer so that the entire cross section of the cell is effective in producing absorption. With this cell the individual steroids and their mixtures as obtained by chromatographic procedures can be recognized routinely in amounts of 25 μ g and under favorable circumstances 3 μ g suffice. The methods of separation and chromatographic analysis have been adapted for small amounts and estimation of ketosteroids by the Zimmermann reaction has been modified so that 2 μ g can be determined. This development has made possible a precise qualitative and quantitative procedure for the establishment of steroid excretion patterns in collection

periods of 1-10 days. The details of the methods applied and the results obtained will be discussed.

Toxicity of tetramethyl succinonitrile and the antidotal effects of thiosulphate, nitrite and barbiturates. R. N. HARGER and H. R. HULPIEU (by invitation). *Dept. of Biochemistry and Pharmacology, Indiana Univ. School of Medicine, Indianapolis, Ind.* Tetramethyl succinonitrile (T S N) and nitrogen are the chief products formed when azo bis-isobutyro nitrile, 'Porofor N' is heated with rubber to make sponge rubber. T S N, M.P. 167°, is quite volatile, air saturated with it containing 120 ppm at 25° and 7820 ppm at 100°. Animals poisoned with T S N exhibited violent convulsions, with asphyxial death in from 1 minute to 5 hours after the first convulsion. Administered subcutaneously, the LD50 in mg/kg was about 30 for rats and 23 for guinea pigs. Two rats receiving 49 and 56 mg/kg per os first convulsed at 5 hours and died several hours later. Intravenously, the LD50 of T S N for rabbits was 20 mg/kg, but 2.5 mg/kg caused convulsions. Dogs were killed by 20 mg/kg or more, given subcutaneously. When T S N vapor was inhaled by rats, 60 ppm killed in 2-3 hours, and 6 ppm caused death in about 30 hours. Neither artificial respiration, thiosulphate, or thiosulphate followed by nitrite had any effect on the toxicity of T S N. Barbiturates administered as needed saved animals receiving up to 50 mg/kg. The use of a quick-acting barbiturate followed by phenobarbital gave the best results obtained. Preliminary experiments indicate that 10 mg/kg of T S N has a greater analeptic effect than 5 mg/kg of picrotoxin, when tested in rabbits with severe phenobarbital depression.

Bacterial synthesis in the rat of an unidentified growth-promoting factor. A. M. HARTMAN (by invitation), L. P. DRYDEN (by invitation), and C. A. CARY. *Division of Nutrition and Physiology, Bureau of Dairy Industry, U. S. Dept. of Agriculture.* Although rats require a chemically still-undefined vitamin, (X), when 35 young were fed an X-deficient diet containing extraordinarily high levels of the 10 B vitamins, methionine and vitamins C, E, and K, 20 rats grew 169 gm and 15 grew only 87 gm in 4 weeks. Twelve of the latter increased in growth from 13 gm per week before to 16, 36, and 32 gm in successive weeks after being fed a single small dose of feces from the former. Additional slow-growing rats fed sulfasuxidine in the diet did not respond to this feeding of feces. These results suggest very strongly that X may be synthesized by microorganisms which may be induced to thrive in the rat. This synthesis was made possible by the extraordinarily high level of riboflavin, 'inoculations' being ineffective with average intakes of $71 \pm S.D. 16 \mu\text{g/day}$. Material(s) with X activity as well as with animal protein factor and antipernicious anemia activities is (or

are) formed simultaneously microbiologically *in vitro* (Stokstad, *J. Lab. Clin. Med.* 33: 860 1948). Crude preparations of B₁₂ and of the 'cow manure' factor are active as X. These results and those of Ott (*J. Biol. Chem.* 174: 1047, 1948) and Bird (*J. Biol. Chem.* 176: 1477 1948) with B₁₂ suggest that all of these factors are either very closely related or identical. X occurs in different combinations in different feeds, all are active in the normal rat.

Isotopic studies of the biosynthesis of nucleic acid components. I. Purines and pyrimidines. MILTON R. HEINRICH (by invitation), D. WRIGHT WILSON and SAMUEL GURIN. *Dept. of Physiological Chemistry, School of Medicine, Univ. of Pennsylvania, Philadelphia, Penna.* The incorporation of carbon dioxide, acetate, and glycine into the nitrogenous bases of nucleic acids and nucleotides in the rat has been studied. After administering C¹⁴-labeled compounds to rats, nucleotides were extracted from the carcasses with acid, hydrolyzed, and adenine isolated. Lipids were removed, nucleic acids extracted with 10% NaCl, and the latter hydrolyzed to individual purines and pyrimidines. Within 7 hours after injecting labeled NaHCO₃ into a rat, a very small amount of radioactive carbon was found in the nucleotide adenine and the nucleic acid adenine, guanine, and uracil. Permanganate degradations showed the isotope to be in the non-ureide carbon of guanine, and the ureide carbon of uracil. When an approximately equivalent total amount of isotope in the form of carboxyl-labeled sodium acetate was injected into rats for 5 days, about the same degree of incorporation was observed. No isotope appeared in the ureide or guanidino carbon of guanine. The highest concentration was found in the ureide carbon of uracil, probably due to incorporation of carbon dioxide. Glycine labeled in the carboxyl position was fed to a group of rats for 10 days, using about twice the quantity of isotope given in each of the previous experiments. Incorporation into the purines of nucleic acids and nucleotides was about 20 times that observed with either bicarbonate or acetate. Very little isotope was found in the uracil or thymine. A sample of the nucleic acid guanine was hydrolyzed with concentrated HCl to give glycine in which the carboxyl group is derived from carbon 4 of guanine. This glycine carboxyl, obtained with ninhydrin, contained essentially all the isotope incorporated into the guanine.

Cytochrome c reductase (DPN). LEON A. HEPPEL (introduced by B. L. HORECKER). *Experimental Biology and Medicine Institute, National Institutes of Health, Bethesda, Md.* The reduction of cytochrome c by reduced diphosphopyridine nucleotide (DPN) has been observed in freshly prepared pig heart suspensions (Lockhart and Potter, *J. Biol. Chem.* 137: 1, 1941) and a partially purified preparation of the enzyme has been ob-

tained from baker's yeast (Altschul, Persky and Hogness, *Science* 94 349, 1941) Lack of information regarding the properties of the cytochrome *c* reductase (DPN) of animal tissues has prompted this investigation The enzyme could be stored for long periods in hog liver acetone powder, from which it was extracted with 0.06 M phosphate, pH 7.4 The turbid extract was incubated at room temperature with crude steapsin After this treatment a considerable portion of the activity was precipitated between 0.4 and 0.5 saturation with ammonium sulfate and on addition of water a clear solution was obtained With extracts not treated with steapsin almost all of the activity was precipitated below 0.3 saturation with ammonium sulfate and could not be redissolved The ammonium sulfate fraction had a pH optimum at 6.8 and the enzymatic activity was precipitated below pH 5.3 By lyophilization a stable powder was prepared which is being subjected to further purification

Degradation of polysaccharides by muscle phosphorylase SHLOMO HESTRIN (introduced by C. F. CORI) *Dept. of Biological Chemistry, School of Medicine, Washington Univ., St. Louis, Mo.* Branched polysaccharides (glycogen and amylopectin) could only be degraded partially ($40 \pm 5\%$) by recrystallized muscle phosphorylase β -amylase limit dextrans of the branched polysaccharides were not degraded to a significant extent by the recrystallized muscle phosphorylase Like β -amylase and potato phosphorylase, the phosphorylase of muscle is thus incapable of degrading starch and glycogen chains beyond their branchpoints The phosphorylase limit dextrin of glycogen differed, however, from the β -amylase limit dextrin of glycogen in respect to priming activity for muscle-phosphorylase Since the phosphorylase limit dextrin afforded roughly an equivalent of one mole maltose per calculated end group when treated with β -amylase, the outer chains of the phosphorylase limit dextrin are probably three or more glucose units long The role of this dextrin in the equilibrium mediated by phosphorylase is discussed

Ataxia and loss of equilibrium in manganese-deficient rats (motion picture) ROBERT M. HILL, DORSEY E. HOLTKAMP (by invitation), A. R. BUCHANAN (by invitation) and ENID K. RUTLEDGE (by invitation) *Depts. of Biochemistry, Anatomy, and Pathology, Univ. of Colorado Medical Center, Denver, Colo.* Shils and McCollum (*J. Nutrition* 26 1, 1943) reported the development of ataxia and poor equilibrium in rats on a manganese-deficient diet Symptoms increased in severity to the 18th day of life when the rats either died or 'recovered to a great extent' We have seen these symptoms in the 2nd, 3rd, and 4th generations of rats on a very low manganese intake, about 0.006 mg/rat/

day In animals placed on low manganese diets after maturity no symptoms appeared Symptoms appeared in 5 female rats in the 2nd generation, 2 before 6 months and 3 between 6 and 14 months of age The latter 3 of these animals raised litters, although poorly Of 3 males and 4 females that were, allowed to reach maturity in the 3rd generation, 1 male and 2 females developed symptoms before weaning One of these females that did not show symptoms was bred and successfully raised one of a litter This one 4th-generation rat, a female, is now 80 days of age and exhibits marked symptoms The symptoms appeared earlier in this rat than in those of the 3rd generation All 8 females with symptoms showed shoulders leaning to the right with the head rotated to the left The 1 male showed shoulders leaning to the left with the head rotated to the right After rotation on a turntable all low-manganese animals showed extreme ataxia and loss of equilibrium Post-rotational nystagmus was normal in direction but slow and of shorter duration than normal

A 16-oxygenated steroid from adrenocortical tumor urine H. HIRSCHMANN and FRIEDA B. HIRSCHMANN (by invitation) *Dept. of Medicine, Western Reserve Univ., and the Lakeside Hospital, Cleveland, Ohio* The triacetate (I) ($[\alpha]_D^{25} = -101^\circ$) of a triol $C_{27}H_{48}O_6$ (provisionally designated as Compound A (Hirschmann and Hirschmann, *J. Biol. Chem.* 157 601, 1945)) isolated from the urine of a boy with an adrenocortical tumor has been reduced catalytically to the triacetate $C_{27}H_{48}O_6$ (II) (m.p. 177-179°, $[\alpha]_D^{25} = -58^\circ$) The same substance has been prepared from the triacetate (III) of the allopregnanetriol-3,16,20 of the urine of pregnant mares (allopregnanetriol-3(β),16(α),20(β) (IV) (Hirschmann *et al.* *J. Biol. Chem.* in press)) The 20-monoacetate of IV was tritylated in positions 3 and 16 and the ditrityl ether (m.p. 170-172°) saponified in position 20 The 3(β),16(α)-ditritoxyallopregnanol-20(β) (m.p. 168-171°) was oxidized with chromic acid in acetone to the 3(β),16(α)-ditritoxyallopregnanone-20 (m.p. 269-270°) which was reduced with lithium aluminum hydride, then hydrolyzed with acid and acetylated to yield 2 triacetates which were identified as compounds II and III Substance II, therefore, is allopregnanetriol-3(β),16(α),20(α) triacetate In view of the change in molecular rotation accompanying the reduction of I it is most probable that Compound A is Δ^5 -pregnenetriol-3(β),16(α),20(α) As this triol was obtained from adrenal tumor urine in a yield of about 6 mg/l it is derived most likely from compounds formed by adrenal tumor cells This finding seems to warrant an inquiry into the corticoid activity of suitably substituted 16-oxygenated steroids and into the possible presence of such compounds in the normal adrenal cortex

Dietary manganese and susceptibility to pneumococcal infection GEORGE H. HITCHINGS, ELVIRA A. FALCO (by invitation) and MARION B. SHERWOOD (by invitation) *The Wellcome Research Laboratories, Tuckahoe, N. Y.* The chief component of the dietary factor which increases the susceptibility of mice to pneumococcal infection (*Proc Soc Exper Biol & Med*, 61: 54, 1946, *Federation Proc* 6: 261, 1947) has been identified as manganese. By the use of a highly purified diet and a minimally infective dose of the pneumococcus (*Type I* SV1 strain) it can be shown that the susceptibility of mice to infection steadily increases with increasing manganese content of the diet to levels as high as 0.6 mg Mn/gm of diet. The effect of manganese in some cases can be partially antagonized by a large excess of dietary cobalt. Similar tests with other types and strains of pneumococci and hemolytic streptococci have resulted in the discovery of several with which the same dietary effect on susceptibility is demonstrable.

Effect of dietary manganese on the growth of white rats DORSEY E. HOLTKAMP (by invitation) and ROBERT M. HILL, *Dept of Biochemistry, Univ of Colorado Medical Center, Colo.* Several laboratories have shown that manganese is an essential dietary factor for growth of young rats, but hitherto no uncomplicated dietary study has been made to determine the optimal manganese intake for this function. In the work reported here, 55 female rats, just before breeding, were divided into 7 groups and put on identical manganese 'free' (6 µg/rat/day) but otherwise adequate basal diets with supplements of manganese in the respective groups added at the following average daily intakes per rat: none, 0.1 mg, 1.0 mg, 5.0 mg, 10.0 mg, 20 mg and 40 mg. These diets were maintained throughout gestation, lactation and the subsequent growth period of the young. Forty-eight litters were obtained of which 38 (194 young) were raised beyond 18 days of age. In the Mn 'free' group 5 litters were born from the 8 females bred, and 3 litters (16 rats) were raised to weaning age. The other 6 groups showed normal birth records with no significant differences between them. Growth records of the young were started on the second and third days and were continued through the 50th day of life. Growth was better with increased manganese supplements up to 5 mg/mother/day. This intake was optimal. Growth was progressively poorer with the higher supplements of 10, 20 and 40 mg/mother/day. At the 40 mg level growth was similar to that on the Mn 'free' diet. The advantage of the optimal level of manganese intake over both higher and lower levels becomes more apparent the longer the diets are maintained.

Quantitative paper chromatography of penicillins I. Use of aqueous solution as developing agent IRVING R. HOOPER, DAVID L. JOHNSON,

AND HAROLD D. TAYLOR (introduced by S. B. BINKLEY) *Research Division, Bristol Laboratories Inc., Syracuse, N. Y.* The commonly known penicillins were separated in paper strip chromatography by development with a sodium citrate solution. 2-Pentenylpenicillin and *n*-pentylpenicillin, moving fastest, were not separated. Benzylpenicillin and *p*-hydroxybenzylpenicillin, appearing together, were not completely separated from the 2-pentenylpenicillin and *n*-pentylpenicillin. *n*-Heptylpenicillin moved slowest and was completely separated. Schleicher and Schuell 589 Blue Ribbon filter paper strips, $\frac{1}{4}$ inch wide were spotted with 0.5 to 2.5 units of penicillin in 0.5 to 5 microliters of solution and then were developed by allowing 40% sodium citrate to flow over the strip in a humidified chamber. After development the strips were placed on *Staphylococcus aureus* inoculated trays which were incubated to demonstrate the position of the penicillins on the strip. The results were photographed. By this procedure benzylpenicillin in mixtures has been determined quantitatively without purification or concentration. The percentages of the penicillins present were determined from the maximum widths of the inhibition zones of two strips with different volumes of a penicillin solution placed on one tray. A statistical analysis was made on the accuracy of the quantitative determination of benzylpenicillin in a series of solutions prepared with known amounts of benzylpenicillin, *n*-pentylpenicillin and *n*-heptylpenicillin. For benzylpenicillin content it was concluded that the observed average for two strips should be within 8.5% of the true value 95 times out of 100 and within 4.2% two times out of three.

Cytochrome *c* reductase (TPN) from liver B. L. HORECKER, *Exptl Biology and Medicine Institute, National Institutes of Health, Bethesda, Md.* Haas, Horecker and Hogness (*J Biol Chem* 136: 746, 1940) have isolated an enzyme from yeast which catalyzes the reduction of ferricytochrome *c* by reduced triphosphopyridine nucleotide (TPNH₂). Cytochrome reductase (TPN) has now been purified from hog liver by extraction of acetone powder with Na₂HPO₄, digestion with trypsin, fractionation between 0.45 and 0.70 saturated (NH₄)₂SO₄, fractionation with alcohol at pH 5.0, adsorption on Al(OH)₃, C γ gel, elution with Na₂HPO₄, adsorption on Ca₃(PO₄)₂ gel and elution with Na₂HPO₄. This procedure yields a pale yellow solution which is 170-fold purified compared to the acetone powder extract. The purified enzyme has a specific activity in the reduction of cytochrome *c* with excess TPNH₂ which is about one sixth that of pure cytochrome reductase from yeast. In the acetone powder extracts the bulk of the activity is associated with insoluble particles from which it is liberated by the digestion with trypsin. The activity is found in the mitochondrial fraction

prepared from fresh rabbit liver by the method of Hogeboom, Schneider and Pallade (*J Biol Chem* 172 619, 1948) The specific activity in these granules is identical with that of the liver acetone powder extracts With purified preparations no reduction of ferricytochrome *c* occurs with reduced diphosphopyridine nucleotide

Penicillin and amino acid assimilation in staphylococci ROLLIN D HOTCHKISS *Rockefeller Institute for Medical Research, New York City* Penicillin is known to cause death of growing, but not of non-growing, bacteria From the work of Gale it appears that those strains of staphylococci which are susceptible to penicillin are dependent upon pre-formed amino acids for growth Gale has also shown that staphylococci grown in penicillin are subsequently unable to take up glutamic acid normally It is difficult to know whether this effect is a cause, or a result, of the primary biochemical damage to these growing cells An effect upon washed cells could not be demonstrated The author has reported (*Federation Proc* 6 263, 1947) that washed, respiring staphylococci can take up amino acids and couple them into cell protein In the presence of crystalline penicillin G (50 u/mg of cells), however, the nitrogen compounds produced are recovered largely or entirely in the suspending medium This is true although the rates and extents of disappearance of amino groups have always been found to be identical in the presence and absence of penicillin, from a variety of simple and complex mixtures of pure amino acids Similar small amounts of ammonia, esterified phosphate and other side products are produced in the two cases Under appropriate conditions, simultaneous utilization of simple amino acids by washed staphylococci leads to the disappearance of uracil from the environment, this disappearance is markedly increased by low concentrations of penicillin Other pyrimidines or purines are not materially affected The uracil utilized cannot be recovered by hydrolyzing the bacteria

Purification, crystallization and properties of circulin, an antibiotic from the bacillus circulans group SPACEY F HOWELL *Biochemistry Section, V D Research Laboratory, U S Public Health Service, Staten Island, N Y* Circulin is an antibiotic of polypeptide nature and has been isolated in crystalline form from the culture fluid of *Bacillus circulans* It is purified by acidifying the culture fluid to pH 2.0, adding acetone to 30% followed by saturation with ammonium sulfate The circulin transfers to the acetone layer Part of the acetone is removed by distillation *in vacuo* The circulin is precipitated from the acetone layer by shaking with chloroform The circulin is dissolved in water and precipitated with ammonium sulfate The antibiotic is dissolved in 70% ethyl alcohol and crystallized at reduced temperature

Circulin can be recrystallized from a number of solvents including 30% ethyl alcohol, methyl alcohol, 70% isopropyl alcohol, 80% acetone and molar sodium acetate solution The form of crystal obtained varies with the solvent Circulin is very stable Water solutions or dry preparations can be stored at room temperature without inactivation Circulin has the following properties M P 235 C, α_D^{20} -93.3, isoelectric point in 0.02M citrate buffer is at pH 7.0 and absorption bands are at 2520, 2580, and 2640 Å The elementary analysis and molecular weight of 1050 indicate a molecular formula of $C_{61}H_{83}O_{15}N_9 \cdot SO_4$ Crystalline circulin is soluble in water (0.3%), 0.7M ammonium acetate solution (2.0%), ethylene glycol (5.0%), and 70% ethyl alcohol (1.5%) at 25 C Although the antibacterial activity of circulin is low, 200,000 *E coli* u/gm, the spectrum is very wide Circulin is toxic to animals

Phosphate turnover of various nucleotides in respiring liver homogenates J P HUMMEL and OLOV LINDBERG (introduced by H A MATTELL) *Wenner-Gren's Institute, Univ of Stockholm, Sweden* To determine the phosphate turnover in the pyridine and flavin nucleotides, a respiring liver homogenate, with glutamate as substrate, was briefly incubated with P^{32} orthophosphate After deproteinization with trichloroacetic acid, the filtrate was saturated with ammonium sulfate and the liver acid-soluble nucleotides (flavin and pyridine nucleotides, adenylic acid, and small amounts of ATP) were extracted into phenol The phenol-extracted material was transferred to water by adding excess ether The water extracts were analyzed by paper chromatography against the following solvents butanol-acetic acid, butanol-phenol, pyridine, phenol, and 2,4,6-collidine Radioactivity on the paper strips was measured directly under a Geiger counter Location of the nucleotides was established by analysis of extracts from the paper Excellent separations of the components were obtained with phenol and collidine Radioactivity was found in a fraction corresponding to ATP, another radioactive fraction was associated with the position of flavin adenine dinucleotide No radioactivity was found with the adenylic acid, flavin mononucleotide, or cozymase fractions On the assumption that only one of the two phosphorus atoms of flavin adenine dinucleotide can exchange phosphate, the specific activity of this phosphorus atom was of the same magnitude as that of the easily hydrolyzable P of ATP This suggests that flavin adenine dinucleotide is intimately associated with aerobic phosphorylation

Anaerobic phosphorylation due to a coupled oxidation-reduction between α -ketoglutaric acid and α -iminoglutaric acid F EDMUND HUNTER, JR *Washington Univ Medical School, St Louis, Mo* When α -ketoglutarate is added to washed

particles from rat liver tissue in anaerobic experiments, essentially no dismutative reactions occur. If ammonium ions are added along with the α -ketoglutarate a rapid reaction takes place. With bicarbonate buffer evolution of carbon dioxide indicates the formation of acid groups. Since the reaction stops when approximately one molecule of carbon dioxide has been evolved per molecule of ammonium ion added, the ammonium ion must participate stoichiometrically rather than catalytically. If ammonia is in excess, the reaction stops when the α -ketoglutarate concentration has fallen to a very low level. These data suggest the almost exclusive occurrence of the reaction $2 \alpha\text{-ketoglutarate} + \text{NH}_3 \rightarrow \text{succinate} + \text{CO}_2 + \text{glutamate}$. This dismutative reaction was observed by Krebs and Cohen (*Biochem J* 33 1895, 1939), but they reported negative results for rat liver. When hexokinase and glucose are added there is considerable phosphorylation of glucose coupled with the oxidation-reduction. The inorganic phosphate removal approaches one molecule per molecule of ammonium ion added, which would be equivalent to one per molecule of α -ketoglutarate oxidized to succinate in the proposed reaction.

Interaction of 9-aminoacridines with proteins and nucleic acids J. LOGAN IRVIN and ELINOR MOORE IRVIN (by invitation) *Department of Physiological Chemistry, Johns Hopkins University, School of Medicine, Baltimore, Md.* The proton acceptor species of 2-methoxy-6-chloro-9-(1'-methyl-8'-diethylamino-octylamino)-acridine (SN-12868) and of quinacrine combine reversibly with bovine plasma albumin and with the proteins of fraction III-1 of bovine plasma. This interaction can be evaluated spectrophotometrically with the equation $\text{pH} = \text{pK}'_1 + \log \frac{(D_1 - D)}{(D - D_2)} + \log \frac{(D_1 - D)}{(D - D_2) + k'_1 [p]}$ in which pK'_1 is the apparent ionization exponent for the group on the aromatic nucleus, k'_1 is the equilibrium constant for the binding of the first acridine molecule to the protein, $[p]$ is the molar concentration of unbound protein at equilibrium, and D_1 , D_2 , D_3 , and D are the optical densities, at a selected wavelength, when the acridine is completely in the form of the proton-donor species (D_1), the free proton-acceptor species (D_2), the protein-bound acceptor species (D_3), and an intermediate equilibrium state (D). For SN-12868 versus bovine albumin in the presence of 1M NaCl to minimize uncertainties regarding ionic strength, $\log k'_1 = 4.37$ (pH 6.7 to 8.3). Binding of this compound by the mixed proteins of fraction III-1 is about one-half the strength of binding by albumin on the basis of total weight of this fraction, and the data suggest a different type of binding. Strong interaction between a cationic species of SN-12868 and sodium ribonucleate (yeast) or desoxyribonucleate (sperm) has been observed spectrophotometrically

in buffered aqueous solutions from pH 6 to 8.6. At pH 6.4 and a concentration of the acridine of $4 \times 10^{-5} \text{M}$, the mid-point of the equilibrium is attained at a concentration of 0.011 gm of sodium ribonucleate per 100 ml.

Difference in electrophoretic behavior of sickle cell hemoglobin and normal human hemoglobin HARVEY A. ITANO and LINUS PAULING (introduced by CARL G. NIEMANN) *Gates and Crellin Laboratories of Chemistry, California Institute of Technology, Pasadena, Calif.* The nature of the phenomenon of sickling of erythrocytes in sickle cell anemia suggests that this disease involves a pathological state of the hemoglobin molecule. The electrophoretic behavior of hemoglobin from individuals with sickle cell anemia and from normal individuals has been studied with the Tiselius apparatus with the collaboration of Dr. S. J. Singer. Ferrohemo-globin and carbonmonoxyhemoglobin from sickle cell blood and from normal blood were studied in phosphate buffers of 0.1 ionic strength at pH values of 5.7, 7.0, and 8.0. A significant difference was found between the electrophoretic mobilities of hemoglobin derived from sickle cell anemia blood and from normal blood in both ferrohemoglobin and carbonmonoxyhemoglobin. The curves of mobility against pH are roughly parallel, the isoelectric point of normal hemoglobin being lower than that of sickle cell hemoglobin for each compound. At pH 7.0 sickle cell carbonmonoxyhemoglobin moves as a positive ion while normal carbonmonoxyhemoglobin moves as a negative ion. The most plausible explanation for the observed differences in mobility is that there is a difference in the ionizable groups in the two hemoglobins. With use of the titration data of German and Wyman it is possible to calculate the approximate difference in net charge between the two hemoglobins. This calculation indicates that the sickle cell hemoglobin molecule in the pH range studied has between 2 and 4 less net negative charges than the normal hemoglobin molecule.

Mechanism of action of phosphoglucomutase VENKATARAMAN JAGANNATHAN (by invitation) and JAMES MURRAY LUCK *Dept. of Chemistry, Stanford Univ., Stanford, Calif.* Phosphoglucomutase was prepared from rabbit muscle by extraction, heating and fractionation with acetone and manganous sulfate. The purified enzyme required Mg^{++} , serum albumin, and sodium sulfite for maximum activity at pH 7.5. It contained non-dialysable phosphorus. When the enzyme acted on glucose-1-phosphate labelled with P^{32} the enzyme became radioactive while the specific activity of the ester-P decreased. The observed values for the subsequent radioactivity of enzyme and substrate corresponded with those calculated on the hypothesis that an exchange between enzyme-P and substrate-P took place. The radioac-

tivity of the enzyme could not be removed by dialysis but after reaction with non-labelled glucose-1-phosphate the enzyme lost its radioactivity on dialysis. After inactivation by iodine the radioactivity of the enzyme was not removed by a similar treatment. An exchange between enzyme-P and substrate-P is postulated as an essential step in phosphoglucomutase action.

Interaction between diisopropyl fluorophosphate (DFP) and proteins of brain tissue. BERNARD J. JANDORF and PRISCILLA D. MCNAMARA (by invitation) *Biochemistry Section, Medical Division, Army Chemical Center, Md.* Rabbit brain homogenates were incubated with 10^{-7} to 10^{-9} M DFP solutions. With these concentrations, the inhibition of brain cholinesterase progresses at a slow rate and requires more than 4 hours at 38°C to become maximal. When DFP containing 15–20 mc P^{32} /gm was used, the initial rate of uptake of P^{32} by the tissue was far higher than the rate of cholinesterase inactivation, near-maximal binding of P^{32} was attained at a time when more than 50% of the cholinesterase activity was still unimpaired. A small but significant uptake of P^{32} was obtained when a brain homogenate, previously treated with a 100-fold excess of unlabelled DFP, was incubated with labelled DFP. When radio-DFP was subjected to mild alkaline hydrolysis, the resulting mixture added to brain homogenates produced no inhibition of cholinesterase activity, and no binding of P^{32} by protein.

Mode of inhibition of chymotrypsin by DFP. II. Elimination of fluorine and introduction of isopropyl. EUGENE F. JENSEN, M-D. FELLOWS NUTTING (by invitation), ROSIE JANG (by invitation) and A. K. BALLS *Enzyme Research Division, Bureau of Agricultural and Industrial Chemistry, Agricultural Research Administration, U. S. Dept. of Agriculture, Albany, Calif.* It has previously been shown by us that the esterase and proteinase activities of crystalline trypsin and chymotrypsin are inhibited by diisopropyl fluorophosphate (DFP). Since both activities were inhibited at the same rate and to the same extent, the activities were considered to be due to the same active groups of the enzymes. Only 17 moles of inhibitor per mole of enzyme (using 40,000 as the molecular weight) were needed for complete inhibition of chymotrypsin, whereas chymotrypsinogen was not affected by DFP. After complete inhibition the resulting inert protein was obtained in crystalline form. After treatment of crystalline chymotrypsin with DFP containing P^{32} , analysis of the crystalline inert protein showed that the chymotrypsin had accepted 16 moles of P per mole of enzyme. Hence all of the phosphorus of the DFP needed for complete inhibition was introduced into the enzyme. Zeisel analyses showed that the isopropyl moiety was also introduced, but only 2.8

equivalents per mole of crystalline chymotrypsin were found. Whether the difference between the amount of phosphorus and that of isopropyl introduced is real or reflects analytical difficulties is not apparent. Fluorine was shown to be absent by spectrographic analysis. Most probably the inhibition reaction is $2 \text{DFP} + \text{XtH}_2 \rightarrow \text{Xt}(\text{DP})_2 + 2 \text{HF}$ where XtH_2 represents chymotrypsin containing two peculiar, active hydrogens. It is felt that a complete knowledge of the mode of DFP inhibition may lead to an understanding of the mode of action of certain enzymes.

Lipids of the nervous system during *in vitro* degeneration. A. C. JOHNSON (by invitation), A. R. McNABB (by invitation) and R. J. ROSSITER *Dept. of Biochemistry, Univ. of Western Ontario, London, Canada.* The changes in the concentration of lipids during the *in vitro* degeneration of cat brain slices and sciatic nerve have been determined after incubation in bicarbonate buffer for periods of time from 1 to 14 days. In brain slices incubated for 14 days there was a great decrease in the concentration of total phospholipid with no change in the concentration of cerebroside or total cholesterol. Of the individual phospholipids, there was a decrease in the concentration of sphingomyelin and cephalin and no significant change in the concentration of lecithin. In sciatic nerve incubated for 8 days there was a significant decrease in the concentration of cephalin and a decrease of borderline significance in the concentration of total phospholipid. There was no significant change in the concentration of cerebroside, free and total cholesterol, sphingomyelin or lecithin. Thus, in confirmation of the work of others, there is a phospholipid-splitting mechanism, possibly enzymatic in nature, in tissue of the nervous system. There are many differences between the degeneration of tissue from the nervous system *in vitro* and the *in vivo* degeneration of peripheral nerve (*Rev. Canad. Biol.* 1949 in press).

Chromatographic separation of bile acids. I. Separation of mixtures of cholic and desoxycholic acids. ARTHUR F. JOHNSON (introduced by ARTHUR H. SMITH) *Dept. of Surgery, College of Medicine, Wayne Univ., Detroit, Mich.* The quantitative separation of milligram quantities of cholic and desoxycholic acids has been accomplished by a chromatographic technique. Hydrated magnesium sulfate (Epsom Salts), in the 40–200 mesh particle size range, is employed as the adsorbent. The adsorbed bile acids decrease the intensity of the fluorescence of the magnesium sulfate making it possible to follow the progress of the chromatogram under ultra-violet light. Empirical sectioning of the completed chromatogram is more convenient for routine determinations. Standard 18-mm diameter chromatographic tubes are packed with dry adsorbent under suction to give

a column 100 mm in length. The acids are introduced in benzene solution and development carried out with an additional 100-200 ml of benzene. After development the column is allowed to dry under suction and divided into four equal portions which are eluted with alcohol. Aliquots of the eluates and of the filtrate are analysed by colorimetric or fluorimetric methods. The cholic acid is found in the eluate from the top quarter of the column and the desoxycholic acid in the bottom quarter and in the filtrate.

Inhibitory action of some antioxidants on rat kidney phosphatase. CARTER D. JOHNSTON (introduced by EDWIN P. LAUG) *Division of Pharmacology, Food and Drug Administration, Federal Security Agency, Washington, D. C.* The inhibition of alkaline rat kidney phosphatase by several compounds proposed as antioxidants in food has been studied in an exploratory manner. The enzyme system consisted of a crude kidney extract, glycerol phosphate substrate, barbitol buffer (pH 9.4) and added Mg ions. Hydroquinone (HQ), nordihydroguaiaretic acid (NDGA), propyl gallate, and thioldipropionic acid inhibit this system 20-25% in concentrations of 0.001 to 0.005M. While 0.005M HQ produces 30% inhibition aerobically, it shows no or very little effect when the experiment is carried out anaerobically in evacuated Thunberg tubes. Quinone, however, inhibits to the same extent under either condition, the degree of inhibition ranging from 80% at 0.005M to 20% at 0.0002M. Quinhydrone lies in an intermediate position. The inhibitory action of HQ thus appears to result from its partial conversion to quinone in the alkaline buffer. Propyl gallate and NDGA show inhibition both in the presence and absence of oxygen. At 0.001M there was a greater inhibition aerobically than anaerobically, but still an appreciable effect in the absence of air (25-40% inhibition). The extension of these studies to related compounds and under a variety of experimental conditions is in progress.

Effects of metabolic inhibitors on membrane potentials. NORMAN R. JOSEPH, ERVIN KAPLAN (by invitation) and C. I. REED *Univ. of Illinois, Chicago Professional Colleges, Chicago, Ill.* Determinations of the membrane potential across the synovialis of the knee in dogs have been made with various electrolytes and nonelectrolytes. With numerous ions the potentials agree with theoretical values calculated from ionic mobilities. With metabolic inhibitors or activators, however, the potentials are of a greater order of magnitude, and appear at lower concentrations. Inhibitors or activators have been classed under five groups: 1) cytochrome inhibitors, 2) heavy metals and other sulphhydryl inhibitors, 3) thiols, 4) inhibitors or activators of succinic dehydrogenase, and 5) electron acceptors, etc., iodine or H_2O_2 . In general inhibitors produce

positive and activators negative potentials. Sulphide yields approximately 400 millivolts, about twice the effect given by cyanide. From the effects of the reagents on the respiratory enzymes, a theoretical explanation of the sign and magnitude of the potentials can be advanced. Hydrogen transfer systems terminate metabolically at one or another of the cytochromes, which are electron acceptors. The electrons are carried to oxygen via cytochrome oxidase, the component having the highest standard redox potential. The mean difference of potential between this component and the original electron acceptor depends on the potential at which electrons are transferred from hydrogen transport systems. The potential difference depends on facilitation or blocking of hydrogen or electron pathways. Asymmetrical increase of the source potential (blocking electrons at cytochrome b) or decrease of the terminal potential (sulphide, cyanide) result in high positive potentials. Decreasing source or increasing terminal potentials produce negative potentials. Experiments on the gastrocnemius of the rat are in essential agreement.

Acetate oxidation by a washed rabbit kidney cortex preparation. GEORGE KALNITSKY *Dept. of Biochemistry, State Univ. of Iowa, Iowa City, Ia.* A rabbit kidney cortex, homogenized and washed in several volumes of NaCl-KCl solution and finally suspended in one volume of NaCl-KCl solution, oxidizes acetate practically completely. Acetate is utilized, oxygen is taken up, and carbon dioxide is evolved, according to the following equation: $CH_3COOH + 2O_2 \rightarrow 2CO_2 + 2H_2O$. The activity of the tissue suspension is proportional to the concentration up to 0.9 ml of the suspension. Veronal, borate and glycine buffers do not inhibit acetate oxidation by this preparation. The pH optimum is in the alkaline range, with the peak at approximately pH 8.6. This preparation actively oxidizes acetate, lactate, caproate and succinate. Citrate is oxidized at a slightly lower rate. Pyruvate, glucose and glutamate are not appreciably oxidized. Mg^{++} and inorganic phosphate increase the rate of oxidation of acetate. Mn^{++} cannot replace Mg^{++} . Kidney cortex was found to be the best source of this acetate oxidation system. Under the same conditions, liver oxidized acetate only slightly. Brain, spleen, lung, heart muscle and skeletal muscle exhibited little or no activity on acetate. Fluoroacetate and malonate at 0.005M concentrations almost completely inhibit acetate utilization, oxygen uptake and carbon dioxide evolution.

Acetyl precursor in aromatic amine acetylation in pigeon liver extracts. NATHAN O. KALLAN and MORRIS SOODAK (introduced by LEWIS L. L. L.) *Biochemical Research Laboratory, New York City General Hospital and Dept. of Biological Chem.*

istry, Harvard Medical School, Boston, Mass The product of the reaction between ATP and acetate in extracts of *E. coli* which appears to be an acetyl precursor in pyruvate synthesis (Kaplan and Lipmann) was tested for activity in the enzymatic acetylation of sulfanilamide. A partially purified fraction was found to promote acetylation under conditions in which monoacetyl phosphate and diacetyl phosphate were ineffective. Coenzyme A is necessary for the acetylation with this compound. Compared with ATP plus acetate the yields of acetylated amine were 50 to 90% at 25°, at 37° the yield was 25% only, presumably due to the much faster rate of destruction. The reactivity as acetyl precursor in pigeon liver extract is apparent but less pronounced than in *coli* extract. This may in part be due to a greater stability of the compound in the latter. Present results suggest however that ordinarily no free acetyl precursor may spill into solution. This is indicated furthermore by experiments on the differential competition for the acetyl donor between the acetyl-trap hydroxylamine and aromatic amines of varied acetyl-affinity. The nature of the primary acetyl donor in pigeon liver and in *E. coli* extracts will be discussed.

Influence of pteroylglutamic acid on glycine and on porphyrin metabolism CECILIA K. KEITH (by invitation) and JOHN R. TOTTER *Dept of Biochemistry, School of Medicine, Univ of Arkansas, Little Rock, Ark* The effect of pteroylglutamic acid (PGA) on growth and on fecal porphyrin production of weanling albino rats receiving standard purified rations or similar rations with 3 per cent sodium benzoate was investigated. The addition of 0.5 mg of PGA/100 gm of purified diet did not influence the growth rate of the animals but elevated the average daily fecal porphyrin excretion from 42 μ g for the control group (12 animals, 28 days) to 50 μ g (12 animals, 28 days) in one experiment and in a second experiment from 68 μ g (8 animals, 24 days) to 94 μ g (8 animals, 24 days). The inclusion of 3% sodium benzoate in the highly purified diets reduced the weekly gain in weight from an average of 21 gm/animal to 5.6 gm/animal. The addition of 0.5 mg of PGA/100 gm of the benzoate-containing diet resulted in an increase in growth rate to 15.5 gm/week/animal. The average daily fecal porphyrin excretion by these two groups were respectively 27 μ g (13 animals) and 37 μ g (12 animals) per rat over a 28-day period. The addition of 2% glycine to the benzoate-containing diet prevented the reduction in growth rate and in porphyrin production brought about by the benzoate.

Effect of dietary pteroylglutamic acid on liver D-amino acid oxidase of young rats BARBARA KELLEY (introduced by PAUL L. DAY) *Dept of Biochemistry, School of Medicine, Univ of Arkansas, Little Rock, Ark* Weanling male albino

rats were given a standard purified diet, with and without pteroylglutamic acid (PGA), for several weeks. The oxygen consumption of the liver homogenates from such animals was measured by the Warburg technic using DL-alanine as the substrate. The inclusion of 5 mg of PGA per kilo of diet resulted in a decreased enzyme activity. The average oxygen uptakes (μ l/gm wet weight of tissue) for 4 groups of control animals receiving the basal diet and for 4 groups receiving the basal diet with added PGA were respectively at the end of one hour, 136 and 111, at the end of 2 hours, 262 and 213, and at the end of 3 hours, 705 and 525. The addition of an excess of coenzyme (FAD) to the reaction flasks resulted in an increase in the oxygen uptake of both groups. The amount of coenzyme present appears to be a limiting factor in this reaction. Data on the activity of other flavin-containing enzyme systems will also be presented.

Demonstration of specificity of a simplified method for the determination of total cholesterol FORREST E. KENDALL, LIESE LEWIS ABELL (by invitation), BETTY B. LEVY (by invitation), J. MURRAY STEELE (by invitation) and BERNARD B. BRODIE *Dept of Medicine, College of Physicians and Surgeons, Columbia Univ, Depts of Medicine and Biochemistry, New York Univ College of Medicine, and New York Univ and Columbia Research Services, Goldwater Memorial Hospital, New York City* Although it has been recognized that neither digitonin precipitation nor color development with the Lieberman-Burchard reagent is specific for cholesterol, one or both of these reactions form the basis of all methods for cholesterol determination. Studies on cholesterol metabolism and its relationship to arteriosclerosis made it imperative to know the identity of the substances being measured by these reactions. A simple method which avoids digitonin precipitation has been devised for cholesterol. Serum is treated with alcoholic KOH to saponify cholesterol esters. After dilution with water the cholesterol is extracted into petroleum ether. The cholesterol content of an aliquot of the petroleum ether phase is determined by the Lieberman-Burchard reaction. Accuracy of the method was checked by recovery experiments. Specificity was assayed by application of Craig's countercurrent distribution technique to the material extracted into the petroleum ether. At least 98% of the material which gave color with the Lieberman-Burchard reagent was cholesterol. This degree of specificity pertained to sera of abnormal as well as of normal cholesterol levels. The new procedure gave results on 100 sera that agreed with the values obtained with the Schoenheimer-Sperry method. Indirectly this demonstrates also the specificity of the latter procedure.

Oxidation of higher fatty acids by isolated rat liver mitochondria EUGENE P. KENNEDY (by invitation) and ALBERT L. LEHNINGER *Depts of Biochemistry and Surgery, Univ of Chicago, Chicago, Ill* It has been difficult to study the enzymatic oxidation of the higher, physiologically occurring fatty acids by preparations of mitochondria from rat liver due to their extreme insolubility and the fact that the fatty acids are themselves potent inhibitors of the oxidase system. By standardizing techniques of preparing substrate solutions it has been found possible to study the oxidation of the normal saturated acids from C_8 to C_{18} . With increase in length of the carbon chain the tendency to form acetoacetate diminishes greatly while the tendency for complete oxidation to CO_2 increases, as indicated by measurements of R. Q., and acetoacetate formed. Purified normal saturated fatty acids (C_{14} , C_{16} , C_{18} , C_{17}) and oleic acid are oxidized essentially completely to CO_2 at high rates as judged by R. Q. measurements. The oxidation of oleic acid has the same cofactor requirements as octanoic acid. Linoleic, linolenic, and vaccenic acids are also oxidized at high rates by the mitochondria. α -Monopalmitin and the more soluble phosphatidic acid prepared therefrom are readily oxidized. It appears probable that oxidation of esterified forms of higher fatty acids is preceded by enzymatic hydrolysis.

Analysis of protein hydrolysates by group separation and paper chromatography of isotopically labelled derivatives ALBERT S. KESTON (by invitation), SIDNEY UDENFRIEND (by invitation) and MILTON LEVY *Dept of Chemistry, New York Univ College of Medicine, New York City* The formation of p-iodophenyl sulfonyl (pipsyl) derivatives of amino acids can be carried out quantitatively (Keston, Udenfriend and Cannan, *J Am Chem Soc* 68: 1390, 1946). The derivatives are separable by paper chromatography (Keston *et al* *J Am Chem Soc*, 69: 315, 1947). The analytical reagent is labelled with I-131. An indicator reagent labelled with S-35 is used to prepare known pure S-35 pipsyl amino acids. When these are added in known quantities to the I-131 labelled unknowns the estimation of the unknown becomes independent of complete resolution and depends only on the S-35/I-131 ratio in any pure fraction. The possibility of errors in identification and of overlapping chromatographic bands is greatly reduced by preliminary separation of the pipsyl derivatives into groups. This may be accomplished by simple counter current techniques. The most hydrophilic pipsyl derivatives (those of aspartic and glutamic acids, hydroxyproline, serine and threonine) constitute group I and are obtained from the aqueous end of a $CHCl_3$ -0.2N HCl extraction system. Group II which consists of glycine and alanine appear predominately in the organic end of a sym-

dichloroethane-0.2 N HCl system. For maximum separation chromatographic development on paper is best done with butanol-isopropanol mixtures for glutamic and aspartic acids (Group Ia), with butanol for hydroxyproline, serine and threonine (Group Ib) and with amyl alcohol for glycine and alanine. In each case the solvent is saturated with aqueous NH_3 solution before use. The bands on the paper are located by radioautography and separated into strips. Constant ratios of counts with and without a filter in successive strips indicates purity. The corresponding S-35/I-131 values are used in the calculations. Several proteins have been analysed by the technique.

Immunochemical studies of factors modifying interaction of egg albumin and rabbit anti-egg albumin WALTER J. KLEINSCHMIDT (by invitation) and PAUL D. BOYER *Division of Biochemistry, Univ of Minnesota, St Paul, Minn* The effect of ionic strength and of pH on inhibition of the EA-antiEA reaction and on dissolution of preformed EA-antiEA precipitates has been investigated by quantitative immunochemical procedures. Inhibition of precipitate formation increases with concentration of NaCl up to 1M but decreases with higher concentrations. With KBr the inhibition increases with concentration up to 3M. KBr produces slight and NaCl no dissolution of preformed precipitates. Definite limits of pH have been established for the EA-antiEA reaction, complete precipitation occurs between pH 6.25 and 8.45. Inhibition of precipitate formation is practically complete at pH 4.2 and 9.5, and disappearance of preformed precipitate occurs in buffer solutions of pH beyond the optimal range. Knowledge of the amino acid composition of egg albumin and γ -globulin allows approximation of the changes of reactive groups with pH. Such calculations indicate that aspartic acid, glutamic acid and lysine play a prominent role in antigen-antibody reactions, while histidine is relatively unimportant. Preliminary experiments have been made on the effect of soluble amino acid derivatives, in particular acetyltyrosine, on the EA-antiEA interaction with the view of further defining the importance of various protein groups in antigen-antibody reactions. Sodium acetyltyrosinate at neutral pH shows a marked inhibition at 0.15M and nearly complete inhibition at 0.5M concentration. Approximately 50% dissolution of preformed precipitate is effected by 0.575M. These effects are much greater than those due to ionic strength alone and may be related to the importance of tyrosyl residues in the interaction.

Penicillin-cytochrome complexes I. M. KLOTZ and W. W. WELSH (by invitation) *Dept of Chemistry, Northwestern Univ., Evanston, Ill* Spectrophotometric investigations have been made which gave direct evidence of complex formation between cytochrome c and penicillins G, K, and X.

tively In the presence of any one of these antibiotics at a concentration of 2×10^{-3} molar, in a phosphate buffer at pH 7.0, the spectrum of the heme protein (7×10^{-5} molar) in the ferristate, develops 2 horns at 520 and 550 m μ , on top of the characteristic broad absorption with a peak at 530 m μ The sample of cytochrome which gave the most striking results was assayed by the method of Rosenthal and Drabkin (*J Biol Chem* 149 437, 1937) and found to be 97% pure Experiments with another sample assaying 54% cytochrome c gave much less pronounced effects It seems unlikely, therefore, that the observed effects are due to spectral changes in hemin impurities All of the penicillins were crystalline samples obtained from the Antibiotics Study Section of the National Institute of Health Of the penicillins examined, K was the most effective in producing the spectrophotometric change, and hence presumably the most strongly bound in this complex As in other anion-protein complexes, penicillin can be displaced from its cytochrome complex by the addition of a competing anion such as sodium dodecyl sulfate (2×10^{-3} molar) This displacement by another anion indicates the importance of electrostatic attraction in the formation of the complex with the antibiotic

Effect of arsenic on the metabolism of selenium

HARLAN L KLUG (by invitation), DONALD F PETERSEN (by invitation) and ALVIN L MOXON *Chemistry Dept, South Dakota Agricultural Experiment Station, Brookings, S D* The alleviation of selenium poisoning by arsenic was first reported from this laboratory in 1938 Since then, the study has been extended to various laboratory and farm animals and the use of arsenic remains the only practical way of counteracting selenium poisoning Relatively little is known about the mode of action of this selenium-arsenic antagonism although it has been suggested that the selenium might be bound by the arsenic in a non-toxic form in the tissues Three groups of rats were kept in metabolism cages and given controlled dosages *per os* for 2 ten-day periods One group received 1 mg/kg of arsenic (arsenite) daily, the second group received 1.4 mg/kg selenium (selenite) daily and the third group received 1 mg/kg arsenic plus 1.4 mg/kg selenium daily Urine and feces samples for each period were analyzed and at the end of the 20-day period the rats were sacrificed and various tissues analyzed The results show that arsenic had little effect on the absorption, excretion or tissue deposition of selenium The conclusion concerning tissue content is also supported by other data from this laboratory Metabolism studies indicate that the lungs may be an important pathway of elimination

Enzymes of liver oxidizing tryptophan to a kynurenine-like compound W E KNOX, KATHLEEN MERO (by invitation), W I GROSSMAN (by invitation), and V H AUERBACH (by invitation)

Rheumatic Fever Research Institute, Northwestern Medical School, Chicago, Ill The metabolic conversion of tryptophan to kynurenine and ultimately to nicotinic acid is evidence for the existence of a new system of enzymes which act on tryptophan Such a system has been obtained, from liver only, of several animal species The soluble enzyme preparation carries out the aerobic oxidation of l-tryptophan in the α -position of the indole ring, d-tryptophan is not oxidized The product of the reaction is a compound similar to kynurenine, but has not yet been completely identified The properties of the enzymes and the nature of the transformations do not agree with those reported by Kotake *et al* for the reactions forming kynurenine The reaction occurs in air, and the rate is doubled by addition of methylene blue The product is a diazotizable amine with a free α -amino group Analyses show the reaction to be 1 l-tryptophan + 2 O — 1 amine No CO₂ is produced The conversion of tryptophan to kynurenine requires the further removal of one atom of carbon One atom is found as formic acid upon hydrolysis of the reaction product Simple fractionation does not separate the preparation into different enzymes On dialysis the need for two co-factors becomes apparent These have been identified as Mg⁺⁺ and adenylic acid

Metabolism of testosterone and androstanediol-3 α , 17 α by liver and kidney homogenates CHARLES D KOCHAKIAN, N PARENTE (by invitation) and H V AROSHIAN (by invitation) *Dept of Physiology and Vital Economics, School of Medicine and Dentistry, Univ of Rochester, Rochester, N Y* In previous reports it was shown that testosterone is metabolized by rabbit liver slices (*J Biol Chem* 170 23, 1947), and homogenate (*Federation Proc* 7 (1) 42, 1948) to Δ^4 androstenedione-3,17, *cis*-testosterone and traces of unidentified compounds Also that rabbit kidney homogenate (*Federation Proc* 7 (1) 42, 1948) converts testosterone in part to Δ^4 -androstenedione-3,17 The homogenates of guinea pig liver and kidney also convert testosterone to Δ^4 -androstenedione-3,17 but in smaller yields than rabbit tissues Furthermore, other as yet unidentified ketosteroids are formed in small amounts These same homogenates convert androstanediol-3 α , 17 α to one or more ketosteroids The metabolites, however, account for less than 5% of the original steroid of which approximately 90% was recovered as crystalline material

Micro molecular distillation of fatty acids ALFRED E KOEHLER and ELSIE HILL (by invitation) *Santa Barbara Cottage Hospital and The Sansum Clinic Research Foundation, Santa Barbara, Calif* Distillation of the neutral fat fatty acids of the blood from a film at 0.03 micron Hg for 30 minutes indicates that some of the fatty acids distill readily at 25° As the temperature is increased more fatty

acids are distilled but at about 60° the curve flattens markedly with only about 75 per cent distilled. This was at first believed to be due to the presence of higher homologues with low boiling points but it was later found that some pure fatty acids undergo changes at the higher temperature that retards their distillation. In general the fatty acids from caprylic to linoleic distill in proportion to their molecular weights at 30°. The following percentages were found: caprylic 100, capric 75, myristic 60, palmitic 32, oleic 20, linoleic 12, and stearic 4. At higher temperatures (40° to 100°) this relationship no longer holds. Palmitic and stearic acid have conventional types of distillation curves but myristic, lauric, oleic, and linoleic acids do not. In fact, myristic and oleic acids at certain higher temperatures may distill less completely than at lower levels. This phenomena is probably explained on the basis of polymorphism. This may occur in the solid phase below the melting point as in the case of myristic acid or in the acids that are liquid throughout the temperature range as in oleic and linoleic acid.

Adaptive enzymatic conversion of l-malate to lactate and CO₂. SEYMOUR KORKES (by invitation), ALICE DEL CAMPILLO (by invitation), and SÉVERO OCHOA, *Dept. of Pharmacology, New York Univ. College of Medicine, New York City*. As previously reported (Korkes and Ochoa, *J. Biol. Chem.* 176: 463, 1948) *Lactobacillus arabinosus* can be adapted to convert malate to lactate and CO₂. The isolated enzyme system requires Mn⁺⁺ and catalytic amounts of diphosphopyridine nucleotide (DPN). The reaction appears to be the combined result of the two reactions (1) l-malate + DPN_{ox} ⇌ pyruvate + CO₂ + DPN_{red} and (2) pyruvate + DPN_{red} ⇌ lactate + DPN_{ox}. The second reaction is catalyzed by lactic dehydrogenase while the first is catalyzed by an enzyme which, except for its DPN specificity, is identical to the one previously isolated from pigeon liver (Ochoa *et al.*, *J. Biol. Chem.* 174: 979, 1948). A study of extracts of acetone powders from either unadapted or malate-adapted cells shows that: 1) Approximately equal amounts of lactic dehydrogenase are present in either case, 2) no 'malate' activity can be extracted from unadapted cells while very high activity is obtained from adapted ones, 3) simultaneously with the appearance of activity toward malate the extracts become able to catalyze the decarboxylation of oxaloacetate to pyruvate and CO₂, a weak fumarase activity also appears. Adaptation to malate can be obtained in a short time with suspensions of resting cells in Warburg vessels if glucose and an allanoin growth medium are also present. Both a supply of glycolytic energy and of anoxia are essential for the adaptation. The partial purification and properties of the enzyme system will be described.

Inorganic pyrophosphate in the enzymatic synthesis of DPN. ARTHUR KORNBERG (introduced by W. H. SEBRELL, JR.), *Experimental Biology and Medicine Institute, National Institutes of Health, Bethesda, Md.* The purification of an enzyme which catalyzes the reaction: nicotinamide mononucleotide (NMN) + adenosine triphosphate (ATP) ⇌ diphosphopyridine nucleotide (DPN) + inorganic pyrophosphate (P-P), has been reported recently (*J. Biol. Chem.* 176: 1475, 1948). An autolyzate of dried brewer's yeast was fractionated twice with ammonium sulfate and precipitated at pH 4.80. The resulting preparation was free of phosphatase activities and was about 1000 times more active per milligram of protein than the original extract. With 50 micrograms of the purified preparation in 1 cc of incubation mixture, equilibrium was reached in 30 minutes at 38° from either direction starting with approximately 2 micromoles each of NMN and ATP or of DPN and P-P. The equilibrium constant, $K = \frac{(\text{DPN})(\text{P-P})}{(\text{NMN})(\text{ATP})}$ is approximately

0.4. These findings indicate a mechanism for the synthesis of DPN and for the origin and function of inorganic pyrophosphate. Current studies with partially purified preparations from brewer's yeast suggest that the synthesis of triphosphopyridine nucleotide involves a direct phosphorylation of DPN by ATP.

Fate of the infecting virus particle. LLOYD M. KOZLOFF (by invitation) and FRANK W. PUTNAM, *Dept. of Biochemistry, Univ. of Chicago, Chicago, Ill.* The origin of virus phosphorus and the fate of the infecting virus particle have been investigated using P³² to label various components of the *E. coli*-T₂ bacteriophage system. Previous study in synthetic lactate medium revealed that the medium itself is the ultimate source of 70% of the virus P (Putnam and Kozloff, *Science* 108: 386, 1948). Extension of these experiments to nutrient broth has yielded substantially similar results. In experiments on the fate of the infecting virus particle T₂ bacteriophage was labeled by growth on *E. coli* in broth containing P³² (2-3 μc/ml). Bacteria in isotope free broth were infected with the purified radioactive virus (60,000 cts/min) under conditions producing a single generation of virus. The phage was purified by concentration in the supercentrifuge followed by differential centrifugation. Prior to infection the radioactivity of the labeled phage was 95% sedimentable at 20,000 g. Upon infection 60% of the counts were absorbed by the host bacterium. After lysis 60% of the radioactivity was non-sedimentable in the supercentrifuge (50,000 g). The low radioactivity of the phage could be accounted for as undischarged P³² used for infection. Disruption of the phage particle is observed in the presence of a high concentration of phosphate.

60 to 400 times that of the progeny. The data indicate that the integrity of the infecting virus particle is destroyed in the course of reproduction.

Pteridines and xanthine oxidase activity EDWIN G. KREBS (by invitation) and EARL R. NORRIS, *Dept of Biochemistry, Univ of Washington, Seattle, Wash.* An enzyme preparation active in the oxidation of either xanthopterin or xanthine was obtained from whey. Spectrophotometric methods as described by Kalckar were used in studying these oxidations. The 'natural' substrate for the enzyme appeared to be xanthine, which was converted to uric acid at a rate about $25\times$ greater than found in the conversion of xanthopterin to leucopterin. Xanthopterin was found to be an effective inhibitor of xanthine oxidation, the inhibition being of the competitive type. The dissociation constant of xanthine with the enzyme was estimated to be 7×10^{-6} , while that of xanthopterin with the enzyme was around 2×10^{-6} . Pteridines with a substitution in the 7-position, such as xanthopterin-7-carboxylic acid, inhibited xanthopterin oxidation as well as xanthine oxidation. These findings may be of significance in explaining some of the observations of Norris and Majnarić on the effects of pteridines in bone marrow cultures or in rats made anemic on a diet containing sulfathiazole. Xanthopterin in low concentrations or dosages was found to stimulate hematopoiesis, but was inhibited in this action by 7 substituted pteridines. In higher concentrations xanthopterin inhibited blood cell formation. This latter effect might be attributed to its possible role as a structural antagonist in purine reactions such as the oxidation reaction discussed here.

Effect of diet composition on rehabilitation following starvation in albino rats W. A. KREHL and W. P. McNULTY, JR. (by invitation), *Yale Nutrition Laboratory, Dept of Physiological Chemistry, Yale Univ., New Haven, Conn.* Experiments conducted with growing and adult albino rats to determine the effect of diet composition on their ability to rehabilitate following 30% loss of body weight as a result of complete starvation led to the following observations: 1) The efficiency of rats in regaining their original weight bore little or no significant relationship to the re-fed diets, the composition of which varied in protein content from 10 to 60% and in isocaloric substitution of carbohydrate with fat. 2) Two of three groups of weanling rats held at constant weight for 5 weeks by chronic inanition were re-fed, respectively, on an optimum artificial ration and on an identical diet, except for the isocaloric substitution of fat for carbohydrate. No significant difference in the rate of gain on the two diets was observed. The third group, placed on a self-selection regimen (after Richter, exhibited a distinctly inferior growth rate, in fact, half the animals failed to select a diet which was satisfactory

for growth by any criterion. A control group of weanling rats placed on self-selection from the start either grew poorly or failed to grow at all. 3) Adult rats placed on dietary self-selection after starvation fell into two groups, a) those that regained at a reduced rate and b) those completely unable to gain. 4) Adult rats starved a second time after recovery either on a prepared diet or on self-selection made a more rapid recovery on this second trial. Furthermore, 100% of the animals placed on the self-selection regimen the second time rehabilitated successfully.

Some properties of Chymotrypsinogen B and Chymotrypsin B VIRGINIA KUBACKI (by invitation), KENNETH D. BROWN (by invitation), and M. LASKOWSKI, *Dept of Biochemistry, Marquette Univ. School of Medicine, Milwaukee, Wis.* Chymotrypsinogen B and Chymotrypsin B were prepared according to previously described methods (*J. Biol. Chem.* 170: 227, 1947; 173: 99, 1948). For the purpose of comparison Chymotrypsinogen alpha and Chymotrypsin alpha were prepared according to Kunitz and Northrop (*J. Gen. Physiol.* 18: 433, 1934-35). Each protein has been recrystallized a minimum of 4 times. Electrophoresis was carried out in a standard 15 ml. cell using a 1% solution of protein in 0.1 M buffers at 3°C. Each of the 4 proteins showed a single component, indicating purity of the protein. A 1:1 mixture of Chymotrypsinogen B and Chymotrypsinogen alpha showed two widely separated components in approximately equal amounts. The non-identity of proteins of the B type with proteins of the alpha type was further proved by pH mobility curves. The zero mobility point for Chymotrypsin B was found at pH 4.7, for Chymotrypsinogen B at pH 5.2, for Chymotrypsin alpha at pH 8.3, and for Chymotrypsinogen alpha at pH 9.1. Solubility studies using Chymotrypsinogen B were conducted according to Kunitz (*J. Gen. Physiol.* 13: 788, 1930). Before the experiment, the material was equilibrated 5 times with the solvent (0.1 M acetate, pH 5.0, 0.27 saturation with ammonium sulfate). The slight deviation from the theoretical curve for one component might have been due to the experimental conditions, or the presence of a small amount of contaminant.

Bixin and the rate of autoxidation of methyl linoleate H. O. KUNKEL and WALTER L. NELSON (introduced by JAMES B. SUMNER), *Dept of Biochemistry and Nutrition, Cornell Univ., Ithaca, N. Y.* The rate of oxidation of methyl linoleate dissolved in triacetin in an oxygen atmosphere was measured in the Warburg manometric apparatus at 25°C. The addition of 130 γ or less of bixin to 50 mg of linoleate in 2 ml of solution decreases this rate of oxidation of the linoleate, while at the same time the bixin is rapidly decolorized. The destruction of bixin proceeds as an apparent first order reaction with respect to oxygen uptake as

contrasted to a first order reaction with respect to time. When a larger amount of bixin (325 γ to 50 mg of linoleate) is added the rate of oxidation is considerably increased, while the bixin is destroyed at the same rate as in the first case. In the presence of light from a mercury lamp, bixin at all concentrations used has been found to produce a more rapid oxidation of the linoleate. This is true even when α -tocopherol has been added to the system at the start. In the presence of α -tocopherol, the bixin is not appreciably destroyed until the end of the induction period, after which its destruction is as rapid as in the experiments first described. Preliminary experiments indicate that carotene acts in a manner similar to that of bixin. Data have also been obtained to show that bixin will enhance the antioxidant action of α -tocopherol.

Certain organic anions and amide and peptide linkages. GRANVIL C. KYKER and SANFORD L. STEELMAN (by invitation) *Dept. of Biological Chemistry and Nutrition, School of Medicine, Univ. of North Carolina, Chapel Hill, N. C.* The rates of hydrolysis at 65°C of the amide and peptide linkages of certain proteins (egg albumin, serum albumin, gelatin and hemoglobin) by hydrochloric acid in the presence of certain organic anions depend on the concentration of the protein, the anion, and the hydrochloric acid and on the nature of the protein. Most important of all is the ratio of the concentration of the protein to the concentration of the anions. The differences in the hydrolytic effectiveness of the organic anions do not parallel, in all cases, the differences in the affinities of the anions of the acids for proteins as suggested by Steinhardt (*J. Research NBS* 29: 315, 1942). A maximum rate of amide hydrolysis is reached with sodium dodecyl sulfonate and egg albumin. This is not the case with the other proteins studied. Sulfosalicylic acid, which has an 'intermediate' anion affinity for wool protein, inhibits amide hydrolysis of egg albumin. The catalytic effect of organic anions on the peptide hydrolysis is limited to the initial stages of hydrolysis and when the protein is further split, the rate tends to approach that of HCl. For the ones studied, when the protein was approximately 25% hydrolyzed the rate began to closely approach that of the HCl. The mechanism for the catalytic effect is uncertain but may be due to the denaturing action of the anion on the protein and to the combination with it. As the hydrolysis proceeds, there is evidently less tendency of the anion to combine and the rate of hydrolysis approaches that of HCl.

Photoelectric colorimetry of pH. GRANVIL C. KYKER *Dept. of Biological Chemistry and Nutrition, School of Medicine, Univ. of North Carolina, Chapel Hill, N. C.* Since the advent of photoelectric colorimeters, many procedures for the colorimetric measurement of pH have appeared as adaptations to various instruments. Such procedures

presume the accurate determination of one color of an indicator in the presence of its other. The colors vary reciprocally with pH. The selectivity of filters employed by photometric instruments to yield monochromatic light is generally inadequate to separate quantitatively the two colors. The effect of one color on the other is compensated by the present method to permit accurate measurements of pH. The choice filter is selected for each of the colors of an indicator. The indicator is added to a sample and instrumental readings are taken using each filter. The two readings are expressed as a ratio. The ratio varies with pH. The procedure affords certain distinct advantages. A source of error is eliminated since the concentration of indicator has no effect over generous limits. When comparing 8, 10, and 12 drops of bromphenol blue, respectively, in 10 ml samples of standard buffers (pH 3.0-4.6) readings varied greatly with concentration (Klett-Summerson blue and green filters) while the ratio remained constant with pH. Indicators, for which neither color is accurately determinable by an instrument depending on filters, may be acceptable. The method has given excellent results in the teaching laboratory, students encountering it the first time obtain titration curves from 5 ml 0.1M lactic acid which superimpose smoothly upon the theoretical. Calibration is done in the usual manner.

Studies on the metabolism of radioactive sucrose in the rat. ALVIN R. LAMB and GEORGE O. BURR *Experiment Station, Hawaiian Sugar Planters' Association, Honolulu, Hawaii.* Recrystallized sucrose, isolated from a sugarcane leaf after photosynthesis in radioactive CO_2 , was given by stomach tube to fully-fed mature rats. Immediately after feeding the 200-mg dose, the rat was placed in a desiccator cage through which air was passed from a tank at a constant rate of 400 cc/min. The CO_2 in the effluent air was trapped in NaOH solution. By means of a by-pass, samples were taken at intervals in Ba(OH)_2 , beginning 1 minute after the sucrose was given, and each 10 minutes thereafter, with increasing intervals later. The BaCO_3 was filtered rapidly on 20 mm paper, dried and counted, using an area of 2.65 sq. cm. In one experiment net counts per minute were 18.9 at 11 minutes, 92.8 at 21 minutes, 285.1 at 51 minutes, 116.8 at 225 minutes and 15.3 at 10.5 hours. Sucrose, therefore, has been absorbed and oxidized within 11 minutes of ingestion, by a fully fed animal. The highest points of the curves of respiratory elimination of radioactive CO_2 were reached in 72-81 minutes. The curves dropped quite rapidly thereafter. Radioactive carbon appeared in the urine within 2 hours. The dried sample registered 223.0 counts/min. Uncontaminated feces registered 25.7 counts/min. The animals were killed after 24 hours. A few p

cal counts muscle glycogen, 43.4/min, bone marrow, 10.9 to 24.7, brain, 19.3, plasma proteins, 32.5, plasma lipids, 5.8, mesenteric fat, 8.7 to 16.6, total carcass residue fat, 7.1

A new metabolic regulator in mammalian spermatozoa HENRY A. LARDY and D. GHOSH (by invitation) *Dept. of Biochemistry, College of Agriculture, Univ. of Wisconsin, Madison, Wis.* Bovine epididymal spermatozoa have comparatively low rates of respiration and aerobic glycolysis and a high rate of anaerobic glycolysis. In contrast, ejaculated spermatozoa separated from seminal fluid by centrifugation have much higher rates of respiration and anaerobic glycolysis and a lower rate of aerobic glycolysis. Thus the Pasteur effect exhibited by the epididymal cells has almost completely disappeared in seminal spermatozoa. These metabolic differences result from the liberation of an extremely labile, lipid-soluble substance from a bound form occurring in the epididymal sperm cell. Until the substance has been characterized we shall refer to it as a 'Metabolic Regulator'. Additions of minute quantities of the purified regulator to epididymal spermatozoa immediately stimulates their respiration and anaerobic glycolysis and abolishes the Pasteur effect. An assay for the regulator has been developed based on its ability to stimulate the fermentation of Bakers' yeast. Using this assay the regulator has been concentrated about 2000-fold from bull semen. It is present also in the spermatozoa of the boar, ram, rabbit and man. In low concentrations the regulator stimulates the oxidation of pyruvate + fumarate and of succinate by washed residue of rat kidney homogenate. It inhibits glutamate oxidation. The regulator functions by uncoupling phosphorylation from enzymatic oxidations.

Esterification of phosphate coupled to electron transport between dihydrodiphosphopyridine nucleotide and oxygen ALBERT L. LEHNINGER and MORRIS E. FRIEDKIN (by invitation) *Depts. of Surgery and Biochemistry, Univ. of Chicago, Chicago, Ill.* Previous work in this laboratory has shown that inorganic phosphate labeled with P^{32} is incorporated into an esterified fraction when dihydrodiphosphopyridine nucleotide ($DPNH_2$) is incubated aerobically with washed rat liver suspension, ATP, Mg^{++} , and cytochrome-c. In order to study this phosphorylation more closely, a system was devised in which $DPNH_2$ was continuously generated by action of β -hydroxybutyric dehydrogenase on β -hydroxybutyrate. The oxidation of the latter by molecular oxygen is not complicated by further oxidation of acetoacetate, which is inert in the system. Oxidation of β -hydroxybutyrate by this system in the presence of ATP, Mg^{++} , catalytic amounts of DPN and cytochrome-c, and inorganic P^{32} causes esterification of the latter. Omission of ATP or Mg^{++} has no effect on the rate

of oxidation but abolishes the esterification, which is therefore not obligatory for the oxidation. Aging of the enzyme at 30° causes loss of phosphorylating activity without affecting oxidative activity. The phosphorylation can also be decoupled from oxidation by arsenite, dinitrophenol, Ca^{++} , and other substances. Phosphorylation does not occur if cytochrome-c is replaced by methylene blue, brilliant cresyl blue, or ferricyanide. Adenylic acid has been used as an acceptor to study the efficiency of the phosphorylation in non-isotopic experiments. The maximum P/O ratio observed has been 1.10, indicating that for each pair of electrons passing from $DPNH_2$ to oxygen, at least one molecule of phosphate is esterified.

Mammalian tyrosinase. Action on compounds structurally related to tyrosine and dihydroxyphenylalanine A. BUNSEN LERNER (by invitation), T. B. FITZPATRICK (by invitation), and W. H. SUMMERSON *Biochemistry Section, Medical Division, Army Chemical Center, Md.* Study of the ability of tyrosinase preparations from the Harding-Passey mouse melanoma to catalyze the oxidation of a variety of monohydroxy and dihydroxy phenolic compounds reveals that, of the various monohydroxy compounds, only tyrosine and its ethyl ester possess significant substrate activity. Compounds such as phenol, dihydroxytyrosine, 4-methoxyphenylalanine, and tyramine are relatively or completely inert as substrates, even in the presence of catalytic amounts of added dihydroxyphenylalanine (dopa), which we have shown promotes the oxidation of tyrosine by mammalian tyrosinase (*Federation Proc.* 7:167, 1948). The 3-amino, 3-fluoro, N-formyl, and N-acetyl derivatives of tyrosine proved to be potent inhibitors of tyrosinase activity. Of the dihydroxy phenolic derivatives, only L-dopa and DL-dopa are significantly effective as substrates, although certain of them (arterenol, catechol, homogentisic acid) resemble dopa in their ability to shorten the induction period in the action of the enzyme on tyrosine, and others (epinephrin, hydroquinone, cobefrin) are rapidly oxidized if dopa oxidation is proceeding simultaneously. The bearing of these findings on the question of substrate specificity of mammalian tyrosinase will be discussed.

Physical stress and liver fat content of the fasted mouse LOUIS LEVIN *Dept. of Anatomy, College of Physicians and Surgeons, Columbia Univ., New York City.* The present experiments confirm previous findings of other investigators that administration of crude pituitary extract to fasting mice causes mobilization of fat to the liver. There are good indications that this fat mobilizing effect is mediated by the adrenal cortex. Data will be presented to show that pure adrenocorticotrophin (Armour) is as effective as crude pituitary extract. Certain physical stresses thought to activate

the pituitary-adrenal system have been tested with respect to liver fat mobilization. Some of these (exposure to cold, severe exercise) are very effective in causing increase in liver fat. The fat increase may be detected within one hour after beginning of exposure to the stress and increases in intensity as the exposure period is prolonged. Other stresses (exposure to high temperature or to low barometric pressure), though indicated to be very severe by the inability of many of the animals to survive, do not increase the liver fat content but instead have a tendency to cause a loss of liver fat. Parenteral administration of glucose during exposure to an otherwise effective stress or during treatment with pituitary extract prevents most of the liver fat increase. However, comparison with the liver fat content of glucose injected, non-stressed mice indicates that the glucose treatment does not completely inhibit the fat mobilizing effect. All procedures which cause increase in liver fat also produce a relative and absolute liver enlargement but the increased liver weight cannot all be ascribed to the accumulation of fat.

Investigation of phospholipid composition in minute amounts. CELIA LEVINE (by invitation) and ERWIN CHARGAFF, *Dept. of Biochemistry, College of Physicians and Surgeons, Columbia Univ., New York City*. The procedures for the chromatographic separation of nitrogenous lipid constituents described recently (Chargaff, *et al.*, *J. Biol. Chem.* 175: 67, 1948) have been extended to the quantitative micro estimation of the bases. Serine and ethanolamine, separated by means of butanol-diethylene glycol-water (4:1:1), were determined in aqueous propanol extracts of the respective adsorbates on filter paper by a modification of the photometric ninhydrin method of Moore and Stein (*J. Biol. Chem.* 176: 367, 1948). Parallel guide strips, developed by means of ninhydrin, indicated the position on the chromatogram of the various amino compounds. Between 2 and 15 γ of each component in 0.01 cc. of solution served for the determination which had an accuracy of $\pm 3\%$. Choline (25 to 100 γ) was estimated with a precision of about 5% in separate chromatograms by the planimetric measurement (Fisher *et al.*, *Nature* 161: 764, 1948) of the molybdenum blue spots produced, as described previously, by the successive treatment of the choline adsorbates with phosphomolybdic acid and stannous chloride. Choline standards were run with each series of determinations. The use of these techniques for the study of the composition of various cellular lipid fractions and for the investigation of novel lipid constituents will be discussed.

Isolation and physicochemical characterization of pituitary follicle-stimulating hormone. CHON HAO LI, *Institute of Experimental Biology, Univ. of California, Berkeley, Calif.* A method for the isolation of follicle-stimulating hormone (FSH)

from sheep pituitaries has recently been described (Li, Simpson and Evans, *Science*, in press). Ca(OH) extract of fresh whole sheep glands was used as the starting material. The extract was next fractionated with $(\text{NH}_4)_2\text{SO}_4$ and FSH activity concentrated in the fraction 0.50–0.75 saturated $(\text{NH}_4)_2\text{SO}_4$. This fraction was extracted with 40% ethanol, the extractable material was then precipitated by adding ethanol to 80%. The alcohol precipitate was finally fractionated again with $(\text{NH}_4)_2\text{SO}_4$ at pH 4.7, FSH precipitated out in the fraction 0.55–0.70 saturated $(\text{NH}_4)_2\text{SO}_4$. The hormone thus prepared behaves as a single protein in the ultracentrifuge and in electrophoresis. It contains approximately 1.3% mannose, 0.6% hexosamine, 0.6% tyryptophane and 4.5% tyrosine. Qualitative analysis indicated that the hormone contains cystine but no cysteine. The results of elementary analysis of the preparation were carbon 44.93%, hydrogen, 6.67%, nitrogen, 15.10%. Electrophoretic analysis of FSH solutions at different pH buffers gave the following mobilities: $+4.8 \times 10^{-5}$ at pH 4.00, $+2.2 \times 10^{-5}$ at pH 4.25, -1.5×10^{-5} at pH 4.60, -1.9×10^{-5} at pH 4.81, -3.0×10^{-5} at pH 5.10, -4.2×10^{-5} at pH 5.60, -6.5×10^{-5} at pH 7.00. These experiments were conducted at 2°C in buffers of 0.10 ionic strength. From these values, the isoelectric point of FSH is estimated to be approximately at pH 4.5. Ultracentrifugal study of one specimen of FSH in a Spinco ultracentrifuge at 165,000 times gravity gave a sedimentation constant, S_{20}^w , to be 4.3 S. Without the values of diffusion constant and partial specific volume, an approximate molecular weight of FSH may be estimated to be 70,000.

Relative size of adrenocorticotropically active peptide fragments. CHON HAO LI, *Institute of Experimental Biology, Univ. of California, Berkeley, Calif.* In previous studies we found that the adrenocorticotrophic hormone (ACTH) isolated from sheep glands preserved its hormonal activity after partial acid or peptic hydrolysis. The active peptide fragments were not precipitated by trichloroacetic acid and were readily dialyzable. We have now found that the average peptide length in the active hydrolysates is approximately 8. In 6 M HCl at 120°C for 24 hours, the hormone hydrolysate contained 6.5% of the total nitrogen as imide nitrogen and 79.4% of the total nitrogen minus the imide nitrogen as the amino nitrogen. These values represent an average of 8 determinations from 1 different ACTH preparations. When the hormone was digested at 37.4°C to the extent of 48–51% with crude pepsin and the hydrolysate fractionated, the corticotropically active material was estimated to be approximately 10% of the total nitrogen.

Experiment No	% of Digestion	Total N of Hydrolysate	NH ₂ -N	N in Peptides	A _v Peptide length
		mm	mm	mm	
83	48	1.04	0.111	0.830	7.5
81	48	1.09	0.099	0.865	8.7
86	50	1.07	0.093	0.850	9.1
87	51	1.07	0.113	0.850	7.5

age peptide length in the hydrolysates was computed and found to vary from 7-9. We are concerned with the isolation of the adrenocorticotropical active peptide(s) in these hydrolysates.

Studies on the biological synthesis of cholesterol from acetic acid. HENRY N. LITTLE (by invitation) and KONRAD BLOCH, *Dept. of Biochemistry and Institute of Radiobiology and Biophysics, Univ. of Chicago, Chicago, Ill.* Studies on the formation of cholesterol in animal tissues carried out with the aid of deuterium have shown that acetic acid is employed in the synthesis of both the isooctyl side chain and the cyclic moiety of the sterol molecule (*J. Biol. Chem.* 145: 625, 1942). Experiments have now been carried out in which cholesterol was synthesized in liver slices from either $\text{CH}_3\text{C}^{14}\text{OOH}$ or $\text{C}^{14}\text{H}_7\text{COOH}$. Degradation of cholesterol obtained from these 2 sources shows that the isotope concentration is higher in the nuclear portion than in the side chain when $\text{CH}_3\text{C}^{14}\text{OOH}$ is the precursor and that the isotope concentration in the side chain at least equals that of the cyclic moiety in cholesterol synthesized from $\text{C}^{14}\text{H}_7\text{COOH}$. Cholesterol formed from acetic acid labeled by C^{13} in the methyl and C^{14} in the carboxyl group contains C^{13} and C^{14} in a ratio of about 1:4 indicating that decarboxylations occur at some stage of the synthetic process. Cholesterol obtained by biosynthesis from labeled acetic acid was converted into cholestane and the latter oxidized with chromic acid to yield the isopropyl group of the side chain in the form of acetone. Isotope analysis of this fraction indicates that the isopropyl group is also derived from acetic acid.

Experiments on the mechanism of coupling between respiration and phosphorylation. W. F. LOOMIS (introduced by Fritz Lipmann), *Biochemical Research Laboratory, Massachusetts General Hospital and Department of Biochemistry, Harvard Medical School, Boston, Mass.* Some aspects of the kidney homogenate technique will be discussed. Preparations, when quick frozen in dry ice, were found to retain practically intact respiration and phosphorylation. Freezing and storage has to occur at around -80°C . At higher temperatures fast deterioration occurs. Phosphorylation coupled anaerobically with ferricyanide reduction was studied and a quotient P/2 ferricyanide of approximately 1 was found. Aerobically a minimum P/O ratio of 2.3 was found in analogous preparations. The already reported inhibition of

the coupling by m-dinitrophenol is also observed with p-nitrophenol but not with p-nitrophenol phosphate. Similar activity was found with di- and trihalophenols but none with diiodo-tyrosine or thyroxine. The apparent substitution in the respiration of tissue dispersions of phosphate by nitro or halophenols has been further explored.

Determination of gamma globulin in blood serum. JOSEPH M. LOONEY and MARY O. AMDUR (by invitation), *Research Laboratory, Veterans Administration Hospital, West Roxbury, Mass.* A study of the method proposed by Kunkel (*Proc. Soc. Exper. Biol. & Med.* 66: 217, 1947) for the turbidimetric determination of gamma globulin with zinc sulfate indicated that the turbidity varied with the albumin concentration. When albumin was added to a 2.0% solution of γ -globulin the turbidity readings obtained were 5.0, 14.0, 10.8 and 8.5 μ , at albumin concentrations of 0.0, 1.0, 3.0 and 8.0% respectively. Irrespective of the γ -globulin concentration on the maximum turbidity was obtained at an albumin concentration of approximately 1.0%. By adding a solution of zinc sulfate to a buffered serum dilution in the presence of gum ghatti a stable opalescent suspensoid, which was proportional to the γ -globulin concentration, was obtained. For the determination, 0.3 ml of serum was mixed with 4.0 ml of barbital buffer pH 7.5 (187 mg barbital and 140 mg Na-barbital/l.) and 2.5 ml of 2% gum ghatti, and then 1.0 ml of $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ (192 mg/l.) was added. After 30 minutes the turbidity was read at 650 μ in a Coleman Jr. spectrophotometer against a blank containing saline in place of the serum. The concentration was determined from a standard curve prepared from pure γ -globulin. The turbidity produced by a given amount of γ -globulin remained constant when the albumin concentration was varied from 0.0-8.0%. Recoveries of γ -globulin added to sera were made in a series of 27 experiments. The mean value of the γ -globulin as calculated was 2.20 gm/100 ml, and that found was 2.15 gm/100 ml. The standard deviation of the individual readings was 0.15 gm. The difference between values exceeded 0.20 gm in only 3 cases. The mean value of γ -globulin found in 32 patients with normal serum proteins was 0.89 gm/100 ml.

Comparative study of growth factors for some lactic acid bacteria. CARL M. LYMAN and J. M. PRESCOTT (by invitation), *Dept. of Biochemistry and Nutrition, Agricultural and Mechanical College of Texas, College Station, Texas.* By means of electrolysis of a dilute solution of liver extract prepared for the treatment of pernicious anemia (reticulogen), the growth factors required by *Leuconostoc citrovorum* 8081 and *Lactobacillus leichmannii* 4797 were separated. The factor for *Leuconostoc citrovorum* migrated toward the positive electrode indicating the acidic nature of the sub-

stance The factor for *Lactobacillus leichmannii* was found in the electrolysis cells nearest to the negative electrode Separation of the factor for *Lactobacillus leichmannii* from the other factor was also accomplished by treatment of a dilute liver extract solution with the anion exchange resin IRA 400 The factor for *Leuconostoc citrovorum* was quantitatively retained on the column while almost 100% of the other factor passed through A striking difference in the stability of the 2 factors toward heating in dilute alkaline solution was found On autoclaving with 0.05 N NaOH at 15 pounds pressure for 30 minutes, the factor for *leichmannii* was completely destroyed while the *citrovorum* factor showed 100% recovery When *Lactobacillus leichmannii* 313 was used as the test organism, the activity of the various fractions indicated above followed very nearly the same pattern as that obtained with *Lactobacillus leichmannii* 4797 Although the factors for *Leuconostoc citrovorum* and *Lactobacillus leichmannii* appear to be distinctly different compounds, they are very probably related In a comparative test on the activity of enzymatic digests of various animal tissues, liver and spleen gave the highest values and muscle tissue gave the lowest values with both organisms The presence of thymidine may have influenced these results

D-serine inhibition of *E. coli* and its reversal by other amino acids and by mutation WERNER K. MAAS (by invitation) and BERNARD D. DAVIS *U S Public Health Service, Tuberculosis Research Laboratory, Cornell Univ Medical College, New York City, and the Naval Medical Research Institute, Bethesda, Md* D-serine produces a nephrotoxic effect in the rat (Artom *et al*, *Proc Soc Exper Biol & Med* 60:284, 1945) Animals can be protected against the action of D-serine by several amino acids (Wachstein, *Arch Path* 43:515, 1947) We have found that growth of normal *E. coli* is delayed considerably by concentrations of D-serine as low as 5 γ /ml In the presence of D-serine the bacteria undergo a few divisions at normal rate Further multiplication is then retarded for a period whose length depends upon the concentration of D-serine, but eventually the organism overcomes the inhibition This adaptation is due not to the formation of an adaptive enzyme, but rather to an adjustment of the environment Of 11 other DL-amino acids tested at 200 γ /ml, none proved to be inhibitory L-aspartic acid, although not inhibitory by itself, greatly enhances D-serine activity Complete antagonism is provided by DL-alanine and glycine Most other amino acids, even in high concentration, produce only partial reversal of the inhibition L-cysteine, L-cystine, L-hydroxy proline and, curiously, L-serine have no effect Spontaneous mutants which are resistant to D-serine inhibition occur with rela-

tively high frequency The mutation rate is greatly increased by ultraviolet irradiation Resistant colonies when grown on D-serine medium together with sensitive bacteria produce a zone of satellite growth of the sensitive bacteria The simple structure of D-serine permits this phenomenon to serve as a model for studying the mechanism of drug resistance

Evaluation of six standard proteins by growth of young dogs DOROTHEA MABEE (by invitation) and AGNES FAY MORGAN *Laboratory of Home Economics, Univ of California, Berkeley, Calif* This experiment was part of a cooperative effort made by several laboratories to standardize methods of assessing the nutritive value of proteins Either 2 or 3 comparable young dogs from our purebred cocker spaniel colony were used for each diet Growth and intake were observed for 120 days, and blood composition and N retention regularly determined Raw egg yolk was used as the control diet The proteins were fed at the 18% level except for the egg yolk and whole egg powder which were fed at the 12% level and the gluten and dried egg albumin at both 18 and 40% levels The apparent absorbabilities were gluten 96, casein 93, casein plus 10% methionine 91, beef 89, peanut 88, egg yolk 87, whole egg powder 82, heated (15 minutes at 140°) casein plus 0.6% lysine 78, heated casein 76, heated egg powder 61, egg albumin 45 If the gain per gm protein eaten for raw egg yolk be taken as 100, that of whole egg powder was 77, beef muscle 73, casein 71, heated casein plus lysine 67, heated casein 65, heated egg powder 61, casein plus methionine 55, peanut flour 41, gluten 28 (18% level) and 34 (40% level), dried egg albumin 25 (18% level) and 9 (40% level) The dried egg albumin contained an active antitryptic agent and the gluten produced running fits The egg albumin was well utilized by rats showing no evidence of antitryptic activity

Determination of hemochromogen in serum WILLIAM M. McCORD (introduced by J. Roy Dorr) *Dept of Chemistry, Medical College of South Carolina, Charleston, S C* Slight hemolysis of red cells interferes with the determination of hemochromogen in serums By determination of 'oxyhemoglobin hemin' and 'total hemin' the serum hemochromogen may be calculated by difference By determining the optical density of a sample of serum, with a Beckman Spectrophotometer, at 576 m μ and at 588 m μ , using water as the blank, the concentration of the hemin, representing the oxyhemoglobin present, may be calculated by using the formula $Hemin_{(O_2)} = (O.D._{576} - O.D._{588}) \times 6.86 \text{ mgs/100 ml}$ Total hemin is determined by adding 8.5 ml of 10% ammonium hydroxide and 0.5 ml pyridine to 1 ml of serum Five ml of the mixture is used as a blank, to 3 ml of the remainder, in the absorption cell, is added 0.1 ml of freshly prepared

20% sodium hydrosulphite ($\text{Na}_2\text{S}_2\text{O}_4$) The optical density is read at $555 \text{ m}\mu$ The total hemin concentration is calculated by using the formula $\text{Hemin}_{(\text{total})} = \text{O D}_{555} \times 34.72 \text{ mgs/100 ml Serum}$ hemochromogen, in terms of hemin, is then calculated by difference Standardization is accomplished by the use of crystalline hemin Sensitivity of the method is of the order of 1 mg hemin per 100 ml with an accuracy of about 5% Bilirubin does not interfere

Stability and stabilization of testicular hyaluronidase D ROY McCULLAGH, FLORENCE VALENTINE (by invitation), and SIBYLLE TOLKSDORF (by invitation) *Dept of Biochemistry, Schering Corporation, Bloomfield, N J* The stability of hyaluronidase which has been dried from the frozen state has been investigated It has been found to decrease as the purity increases Bulk enzyme assaying 150 Turbidity Reducing Units per mg does not measurably decrease in potency on standing at room temperature for several months 500 TRU/mg material has a half life of approximately 3 months Hyaluronidase can be sterilized by filtration without destruction When it is packaged in vials, losses are occasionally observed during drying The lability is greater when the amount of enzyme in the vial is very small The enzyme in vials is stable for several months at 5°C , but at room temperature it decreases considerably in potency in 2-3 months At 60°C the aqueous solution is almost immediately destroyed In the dry state at 60°C the half life may vary from a few hours to a few days according to the amount of enzyme in the vial It has been found that the addition of small quantities of gelatin will greatly increase the stability of hyaluronidase However, when gelatin is included in the solution to be dried, the final product is not readily soluble Therefore, a polypeptide derived from gelatin has been used as a stabilizer When this material is used the potency decreases only 15-20% in 7 weeks at 60°C The product is very soluble in water Various bacteriostatic agents have been used in conjunction with hyaluronidase and do not appear to destroy the activity

Further studies on enzymatic benzoylations R W MCGILVERY (by invitation) and P P COHEN *Laboratory of Physiological Chemistry, Univ of Wisconsin, Madison, Wis* The study of enzymatic benzoylations has been extended to the conjugation of ornithine by the fowl The washed residue of chicken tissue homogenates couples p-aminobenzoic acid (PAB) with N^6 -benzoyl-L-ornithine to form p-amino-L-ornithuric acid The product has been isolated as the p-(p-hydroxyphenyl) azo derivative N^a -benzoyl-L-ornithine also reacts with PAB, presumably forming p'-amino-L-ornithuric acid, but this reaction has not been studied in detail Adenosine triphosphate (ATP) is required for the synthesis Other properties of the systems will be reported

Growth stimulatory factors for the malarial parasite, Plasmodium knowlesi RALPH W MCKEE and QUENTIN M GEIMAN (by invitation) *Depts of Biological Chemistry, and of Comparative Pathology and Tropical Medicine, Harvard Medical School, Boston, Mass* Submaximal growth and multiplication of *Plasmodium knowlesi* are obtained when a nutrient medium of known composition (*J Exper Med*, 84 607, 1946), simulating plasma, is used The addition of at least 2, apparently different, factors stimulate *in vitro* growth and multiplication of the malarial parasites One factor is a dialyzable component (or components) present in horse, monkey and human plasmas In a washed erythrocyte culture system, to which are added the nutrient medium and purified serum albumin or globulin, growth and multiplication are retarded The addition of either plasma or the dialyzable component restores the activity This growth stimulatory substance is organic and appears to be quite heat stable as deproteinization with heat at pH 5 does not destroy the activity The other active material is a non-dialyzable substance (or substances) present in 15 unit antipernicious anemia concentrate of liver The liver concentrate (0.005 ml per culture) increases the rate of growth and the numbers of parasites to as much as 150% of that obtained when plasma alone is present The addition of folic acid or of additional p-aminobenzoic acid appear to have no stimulatory action Vitamin B_{12} remains to be tested Further chemical and isolation studies are under way on these factors

Rate and mechanism of the Liebermann-Burchard reaction on various derivatives of cholesterol HERBERT MCKENNIS, JR, JOSEPH Y THOMAS (by invitation) and J C FORBES *Dept of Biochemistry, Medical College of Virginia, Richmond, Va, Dept of Physiological Chemistry, The Johns Hopkins Univ School of Medicine, Baltimore, Md and Laboratory for Surgical Research, Medical College of Virginia, Richmond, Va* During the course of our investigations of the effect of various derivatives of cholesterol on growth it became desirable to know the comparative behavior of these substances in the Liebermann-Burchard reaction The results of rate studies at bath temperatures of 10° and 22° appear to indicate a process which is kinetically of the first order In view of the recent isolation of dicholesteryl ether from the spinal cords of cattle (Silberman, N, and Silberman-Martyncewa, S, *J Biol Chem* 159 603, 1945) it was particularly interesting to study this ether On a molar basis the amount of color produced was essentially twice that from cholesterol itself This finding gives indirect support to Yoder's conception of cholesteryl ether cleavage by a cholesterol-cholesterilene route It further opens to question the view (Nath, M C, Chakravorty, M K, and Chowdhury, S R, *Nature* 157 104, 1946) that

dicholesteryl ether is not an intermediate in the production of the Liebermann-Burchard color

Formation of formaldehyde in the biological oxidation of the methyl group of sarcosine COSMO G MACKENZIE and VINCENT DU VIGNEAUD *Dept of Biochemistry, Cornell Univ Medical College, New York City* In the course of studies on the biological oxidation of the methyl group in S- and N-methyl compounds, radioformaldehyde has been obtained as an oxidation product of sarcosine labeled in the methyl group with C¹⁴. The formaldehyde has been isolated as the dimedon derivative from the trichloroacetic acid filtrate of rat liver homogenates incubated with the labeled sarcosine. This derivative of formaldehyde has also been isolated by direct distillation of the incubation mixture from 0.1 M H₂PO₄ into aqueous dimedon. Free formaldehyde is formed in the course of the oxidation of the methyl group as can be shown by blowing it out of the incubated homogenate-sarcosine mixture with a stream of N₂ at 37° and trapping it in a solution of dimedon. The formation of free formaldehyde from the methyl group of radiosarcosine by respiring liver slices may similarly be demonstrated by drawing a stream of O₂ through the reaction vessel and into a dimedon scrubber. A positive color test for formaldehyde in liver homogenates incubated with sarcosine has been reported by Handler, Bernheim and Klein (*J Biol Chem* 138: 211, 1941). The homogenate described by these authors was employed in the present experiment. Radioactive CO₂ has also been obtained as a product of the oxidation of the tagged methyl group of sarcosine both in liver preparations and in the whole animal.

Specific volume of α - and β -casein and relationship of specific volume to amino acid composition T L McMEEKIN, M L GROVES (by invitation) and N J HIPP (by invitation) *Eastern Regional Research Laboratory, Philadelphia, Penna* The specific volume of a protein is of great importance in determining its molecular weight by sedimentation and diffusion. It has been suggested by Cohn *et al* (*J Biol Chem* 100: Proc. xxviii, 1933) that the apparent specific volume of a protein is largely determined by the volume increments of the amino acid residues of which it is composed. The fairly complete amino acid analyses of α - and β -casein reported by Gordon *et al* (*Federation Proc*, this issue), which show considerable differences in the composition of these proteins, offer the opportunity of testing the accuracy of the hypothesis that the specific volume of a protein is determined by its amino acid composition. The apparent specific volumes of α - and β -casein, as well as unfractionated casein, have been determined in dilute alkali and in acid solutions. The following data illustrate the agreement of the experimentally determined specific volumes with the specific volumes calculated from the amino acid analyses of Gordon *et al*.

	Apparent Sp Vol Calculated from Amino Acid Residues	Apparent Sp Vol Determined at 25 C
α Casein	0.728	0.724
Unfractionated casein	0.732	0.727
β Casein	0.744	0.740

Lipids of peripheral nerve during Wallerian degeneration A R McNABB (by invitation), A C JOHNSON (by invitation) and R J ROSSITER *Dept of Biochemistry, Univ of Western Ontario, London, Canada* It has previously been shown (*Rev Canad Biol* in press) that when a cat peripheral nerve undergoes Wallerian degeneration there is a steady decrease in the concentration of the myelin lipids, i.e. cerebroside, free cholesterol and sphingomyelin, the substances which we have previously suggested are the principle lipid components of the myelin sheath (*Biochem J* 43: 573, 578, 1948), and an increase in the concentration of the ester cholesterol. Further observations on the concentration of neutral fat and total fatty acid make it possible to piece together the changes in the distribution of lipids in a nerve when it undergoes Wallerian degeneration. There is an early increase in water content and a reduction in the concentration of neutral fat. After 8 days, corresponding in time to the appearance of macrophages along the course of the degenerating nerve, there is a steady decrease in the myelin lipids, i.e. cerebroside, free cholesterol and sphingomyelin. These substances are presumably slowly hydrolysed, and the products of hydrolysis, e.g. glycerol, fatty acid, choline, galactose, sphingosine and phosphate are removed. There is, in addition, a hydrolysis of cephalin and a slower hydrolysis of lecithin. Some of the fatty acids liberated during hydrolysis presumably combine with free cholesterol to form ester cholesterol while others may be converted into neutral fat. Such a process would explain many of the histochemical observations made on degenerating nerve tissue.

Distribution of radiophosphorus in rabbit tissues after injection of labelled disopropyl fluorophosphate (DFP) PRISCILLA D McNAMARA (by invitation) and BERNARD J JANDORF *Biochemistry Section, Medical Division, Army Chemical Center, Maryland* Sublethal doses of DFP, containing 15-20 mc of P³²/gm, were injected intravenously into rabbits. Upon sacrifice of the animals from 10 minutes to 24 hours after injection, the specific radioactivity (P³²/unit tissue weight), in decreasing order, was found to be high in kidney, plasma, lung, and liver, moderate in skeletal muscle, heart, and erythrocytes. The specific activity of cerebral tissue was low even after injection of DFP into the carotid artery. Thus, no correlation was found to exist between the cholinesterase activity of these tissues and their ability to retain P³² derived from DFP. The magnitude of specific

activity of rabbit organs depended on the time interval between injection and sacrifice of the animal, while their order of relative activity was independent of this interval. Kidney and liver tissue of animals injected with DFP and sacrificed at intervals showed a decrease in total specific activity with time, however, the proportion of protein-bound to total radioactivity in these organs increased steadily during the same interval. In lung tissue, a maximum value for total and protein-bound P^{32} was attained within 10 minutes after injection, these values decreased only slightly during the subsequent 24-hour period. When DFP was replaced with an equivalent dose of sodium diisopropyl phosphate, little or no P^{32} was retained, 24 hours after injection, in the tissues mentioned.
